Dr F C **Hotz**, Chicago—The closing remark of the Doctor alludes to cases we have all seen that have gone through the hands of our colleagues, have been refracted by them, and in which we find that our examination would not confirm or sustain the prescription for glasses which the patient received at the former examination If the eyes have changed in a considerable number of these cases, it should certainly put us on our guard and keep our mouths shut as to what we think of the glasses the patient has When I read the title of the paper in the preliminary program it interested me particularly, because just at that time an old patient of mine had returned, showing a decided change in the astigmatism I therefore went over the records of this year and last in my case book to get an idea how many cases I might fish out that had returned The trouble is that a great many patients who consult us, if the glasses become unsatisfactory in time, go to some one else for the second examination, and we never know whether their astigmatism has changed or not I was surprised, though, in such short space of time, a few months more than a year, to come across a half dozen cases that I had examined years before, and in which a re examination now showed a marked and interesting change in the astigmatic condition The examination of the past had been made under mydriasis and the re examination was made under the same conditions If in the first instance atropin had been used I used the same in the re examination, and if at first it was homatropin, I used the same drug again, so the conditions of the examinations were absolutely the same, and if the results differed, it must have been due to change in the eye during the intervals In one of my cases examined in 1887 each eye then needed — 75 D cyl, and in 1897 each eye needed — 1 50 D cyl A second case shows a change from emmetropia to a high degree of myopic astigmatism In 1887 the patient, then 20 years of age, after recovery from an attack of iritis and while the eyes were still under the full effect of a mydriatic, showed emmetropia In 1889 the left eye showed a myopia of 6 D with astigmatism of — 3 50 D cyl ax 15 In the spring of this year the condition has changed to a myopia of 7 50 D in one eye, with —5 D cyl ax 15

A third case shows in 1890, right eye required + 3 D cyl In 1893 it required a — 1 D s with + 4 D cyl, and in 1897 — 2 D s with + 5 D cyl, showing that while one meridian retained its hypermetropia, the other became myopic Then I came across three cases in which hypermetropic astigmatism had increased This is most remarkable, because we know from statistics that if the eye is changed during school life, the tendency is to develop myopic conditions

Dr G C **Savage**, Nashville—On my arrival I told Dr Bane that he had made but one omission, and that was in leaving out the ophthalmometric measurements That these changes take place no one can deny, but where it takes place is a matter undecided In the first place allow me to say there is one of my patients who has never been able to get away from me, that is myself In Philadelphia where they do refraction work to perfection, I was given a — 50D cyl and a little later I found I was not fully corrected until I used a —1 50D cyl axis vertical A little later I found still more, and nine years ago the first ophthalmometer I ever saw, in the office of Dr Swan N Bur nett, showed —2.25D cyl in each eye I am wearing that glass to the present time - What does this mean? I believe the radiating fibers of the ciliary body help to correct the astigmatism, and that they are not under the control of the third nerve I do not believe they are reached by the mydriatics, and hence it is impossible to control them except by teasing out the astigmatism A slight contraction of the meridianal fibers will tilt the lens one way and those of another portion will tilt it another direction, and astigmatism is increased at right angles to this tilting ' I think my case and others which I have observed, show that we have seldom, if ever, any increase of the corneal astigmatism, but that the increase is due to tilting of the lens, and we must tease this out until we get the maximum of astigmatism, when a given lens will serve its purpose forever

Dr H V **Wurdemann**, Milwaukee—I wish to mention one factor in the correction of astigmatism that has not been spoken of, that is lid pressure We all know that intense blepharospasm or a chalazion will produce astigmatism, which after the spasm or pressure has been relieved, passes away Now there are some patients with astigmatism against the rule, who are in the habit of correcting it in part by lid pressure We totally correct the astigmatism as it appears and we find the patients relieved, but if we examine them later we find a recurrence of astigmatism, the elasticity of the cornea having asserted itself, and instead of, say 2 diopters of corneal astigmatism, we find 3 or 3½ to correct

Dr T A **Grigg**, Butte, Mont —I have listened to these papers with much interest and can not wholly agree with most of the speakers on the subject My opinion is that the astigmatism that has not been fully corrected It was there, and the mydriatic, homatropin or atropin has not been used in sufficient quantity, or not long enough to overcome the defect Again, in young people the elasticity of the lens is great, and you will often see those people that have a considerable amount of astigmatism, as much as 2 or 3 diopters, who before you used any mydriatic in the eye could possibly read 6/6 quite distinctly and who after you have used the mydriatic could not read more than about half that amount, and at the same time you would not have fully overcome the ciliary muscle One of the gentlemen spoke of using tablets of cocain and homatropin It has been my experience in using cocain that it produces an astigmatism itself, that it acts upon the corneal epithelium and gives, as it were, a false astigmatism I know that in old people past 45, where I was timid about using atropin and used cocain, so as not to produce a glaucomatous condition, I have produced an irregular astigmatism, which I could not bring out later on when I tried again to refract the eyes I think if the physicians present today will watch their cases where they use cocain to dilate the pupil and overcome the action of the ciliary muscle, and will later on refract these eyes again they will note entirely different results I remember an aphorism I read in a little book, I think written by Dr Fox of Philadelphia, which is that astigmatism is an invisible and subtle child of the devil, whose hiding place is the ciliary muscle of the eye, and he is said to hate atropia as his father hates holy water

Dr **Minney**—I have noted this difficulty ever since I began to practice ophthalmology, and I supposed it was due to two causes, first, because I had not the ability to fit these patients, and, second, because some changes did take place I do not know why these changes can not take place, and I think we must believe that they do

Dr J L **Thompson**, Indianapolis—The gentleman is correct about that, and I am not surprised at anything that can take place in the eye It is true that if I took one out I should be surprised to see it grow in again, but nothing short of that would astonish me I have seen cases that I examined years ago and gave them plus cylinders, and when examined again ten or fifteen years later, I found that they had changed from positive to negative astigmatism You will see some gentlemen writing today that they can calculate, in cases of myopia where they propose to remove the lens, what glasses the patient will have to wear afterward They know nothing about it One can not make such mathematical calculations for the human eye

Dr **Edward Jackson**, Denver—The subject brought before us is one well worthy of study, and when we have accumulated enough definite facts bearing upon it, we shall know a great deal more about the changes that lead to astigmatism, and the ways of influencing it aside from correction by glasses In 1890 I reported to the American Ophthalmological Society, a series of 18 cases of increase in hypermetropic astigmatism I was interested in the subject first by my own case, which was similar to that of Dr Savage There was no question, I think, as to the refraction at the first measurement My eyes were measured repeatedly in experimenting with different mydriatics, requiring 50D cyl for one eye and 75D cyl for the other After two or three years of hard eye work with a microscope, etc , I found something wrong with my glasses and an examination then showed that the astigmatism had increased to 1 25D in each eye Two or three years later they showed 1 75D in one eye and 2D in the other That was over eight years ago, and it has remained entirely constant since that time, though I have been examined within the last year

My earlier histories of such cases are not good, because I did not then use the ophthalmometer in all cases But I can say now that these changes in astigmatism do not depend in all cases upon change in the cornea, nor are they in all cases independent of this Perhaps the ophthalmometer will be of some value in practice for this purpose I hold it to be of very little practical value unless it will be in this way, to follow up and detect the changes in the cornea Astigmatism against the rule is more apt to arise after the age of fifty than before, which looks as if these cases were dependent upon some change in the shape of the lens, or its position, I think likely the latter

Dr H B **Young**, Burlington—With one exception I believe I am a doubting Thomas in regard to this change and I would like to remind Drs Savage and Jackson that in their arguments I think they proved the opposite of what they intended They stated that when they got to a certain point their astigmatism remained steady If the conditions were changing, why did they stop eight or nine years ago

It has been my fortune to examine quite a number of cases of what is popularly known as second sight, the refusal of glasses by people of 60 or 70 years of age, who have been using glasses previously In examining nearly all of those cases I have found beginning opacity in the periphery of the lens and all showed a development of astigmatism against the rule We find an astigmatism of this kind after operating upon cataract and the question arises in my mind whether that is purely an aphakic astigmatism that we see after cataract operation

Dr C E **Norton**, Lewiston, Me —Some years ago I had a case that bears on this point and I am sorry that I can not at present give the exact facts concerning it It was a young man who came to me with a difficult error of refraction and on examination I gave glasses that were satisfactory for some time He came to my office later with a chalazion of the lid, not giving him any pain, but he was prepared to find his sight in that eye defective and thought he could not see distinctly with the old glasses I had given him In my first examination I had used the ophthalmometer and had a record of the findings In the second examination, in which I also used the ophthalmometer, I found that there had been a change in the corneal astigmatism, but having about that time read of a similar case I thought it possible that this might be due to pressure of the tumor and suggested that we operate on the lid before making any change in the glasses This was done, and in the course of a few weeks his vision had improved and the ophthalmometer showed the same record it did in the first examination I do not remember where I read the account of the tumor in the lid that changed the corneal astigmatism

I think this question opens a field for investigation and I do believe that in the ophthalmometer we have an instrument of great accuracy in estimating the corneal astigmatism and I think this study of Dr Jackson's will be extremely interesting I differ with him as to the practical value of the ophthamometer in office work for I use it constantly and feel that it is one of the most important instruments that I have It is well known that many of the New York oculists have much faith in it, while the Philadelphia men, as a rule, have none

Dr **Henry Gradle**, Chicago—I would like to quote the most extreme change in the degree of astigmatism I have witnessed A girl of seventeen years, examined in 1892, showed a myopic astigmatism of 1 50 D cyl ax 180 The tests were so decisive and the vision so perfect (-%o corrected) that no mydriatic was used and the patient was fully satisfied with the glasses She returned in 1894, stating that the old complaint had returned, but she had been free from discomfort for four years I found now 4 50 D cyl with the rule and with the best correction scarcely more than 2%o vision Under a mydriatic the astigmatism remained the same, but 1 D of hypermetropia in the opposite meridian was brought out making the refraction now=Sph +1 with Cyl —4 5, axis horizontal

I have seen two instances where astigmatism had been produced by the pressure of a chalazion and where the subjective findings changed completely within two weeks after removal of the tumor

Dr **Bane**—The facts that I wanted have been brought out Certainly the remarks that have been made prove that astigmatism does change, both in amount and its meridian As to the latent astigmatism theory, I think it is hardly tenable The gentlemen who have spoken have nearly all used mydriatics to an extent which would have brought it out if it were present

---

THE CONSERVATIVE TREATMENT OF EPIPHORA AND AFFECTIONS OF THE LACHRYMAL APPARATUS

Presented to the Section on Ophthalmology, at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo, June 7-10 1898

BY S D RISLEY, M D
PHILADELPHIA

It is the purpose of this paper to urge the importance and value of conservatism in the treatment of lachrymal obstruction The ophthalmic surgeon meets with no more numerous, annoying or persistent class of affections than those involving the lachrymal apparatus, especially that part constituting the drainage system Pathologic processes affecting any portion of this delicate apparatus lead to a partial or complete closure of its lumen and thus obstruct the flow of tears from the eye into the nose The symptoms of lachrymal retention and the secondary consequences are too well known to require any extensive recital It should however be borne in mind that the ocular affections which often precede or cause the disease of the lachrymal passages, become chronic and persist against all measures of treatment by virtue of the evil results of the retained tears, thus constituting a vicious circle, to be broken only by the judicious treatment of the lachrymal obstruction The retention of tears may be partial or complete, bearing more or less definite relation to the degree of obstruction in the drainage system Partial closure of some portion of the duct may exist and cause no notable obstruction to the outflow of the tears except under circumstances which increase the requirements by producing excessive secretion, e g when the emotions are excited or on exposure to strong winds or irritants, or by the still further contraction of the tissues caused by exposure to cold These minor cases of partial retention are doubtless frequently overlooked, and the eye treated by washes and astringents directed to the cure of mild forms of chronic conjunctivitis caused by the retained tears The obstruction may be at any part of the drainage system, e g at the puncta, one or both, in the canaliculi, lachrymal sac, or nasal duct, or, by a closure of the duct at its nasal orifice from swelling of the tissues overlying the inferior turbinated bones

A very frequent cause of partial retention is a more or less complete obliteration of the inferior punctum, or a narrowing of the lumen of the canaliculus, the sac and nasal duct being normally patulous In these cases it is usually necessary only to dilate the punctum, or punctum and canaliculus by a delicate needle probe, a single dilation often effecting a cure It should be done without sufficient violence to set up inflammatory reaction, which might increase instead of relieving the contraction If the trouble is in the punctum alone it is occasionally necessary to cut its sphincter muscle, and thus to convert it into a slit Where the obstruction is confined to the punctum or canaliculus it is obviously unnecessary to subject the patient to the annoyance and pain of probing the nasal duct The absence of obstruction in the sac or nasal duct can be determined by the ready flow of a stream of warm boric acid, or salt solution, injected through the dilated punctum or canaliculus, by inserting the fine point of a suitable syringe If the solution flows freely into the nose it is obvious that the sac and nasal duct are patulous, but should it flow backward into the conjunctival sac through the upper canaliculus it is equally plain that these passages are occluded and some estimate as to the locality of the obstruction may be made by the quantity of fluid injected before the return current is observed A fine bulbous probe may then be inserted, without slitting the canaliculus, in order to explore the passage If it passes through the duct readily, meeting with obstruction only at the nasal orifice, the nasal passages should then be carefully studied and any existing disease properly treated A few cases of lachrymal retention need no other treatment than to free the nasal end of the duct from existing synechia between the inferior turbinate and the floor of the nose, or from hypertrophy of the mucous membrane surrounding its orifice My attention was first called to the importance of nasal disease in causing lachrymal obstruction in 1879 I had treated a gentleman for many weeks quite unsuccessfully by probing the duct, after slitting the canaliculus He called my attention to some discomfort he was suffering in the nostril of the same side A superficial ulcer was discovered on the floor of the nose which spread itself into the region of exit of the nasal duct After careful cleansing this was painted with a solution of nitrate of silver He returned on the second day with the ulcer quite healed, and his lachrymal retention cured In some cases therefore it is important to explore the nostril before adopting radical measures addressed directly to the lachrymal apparatus In my experience these cases of nasal disease furnish a relatively small percentage of the cases of the retention of the tears but are still sufficiently common to suggest a routine study of the nose in all cases. The obstruction exists however, in the vast majority of cases, in some portion of the nasal duct and usually at or near its upper end. Considerable variety is presented both as to the degree of obstruction presented to the flow of the tears, and the nature and extent of the constriction in the duct. These variations manifest themselves in the symptoms and history of the affection, and to the prudent surgeon suggest widely differing methods of treatment. In a comparatively limited group of patients I have found a thin paper-like stricture situated at the bottom of the lachrymal sac, and spreading itself like a membrane over the orifice of the bony nasal duct, effectually preventing the exit of the tears. In these cases a fine Bowman's probe can be forced through the membrane, and the rent thus made may be dilated afterward by successively larger probes, but the stretching or dilation affords only temporary relief since the membrane very soon contracts again and the obstruction is once more complete, the membrane becoming thicker, more dense and unyielding with each repetition of the procedure. This group of patients furnish the only examples where cutting operations are justifiable or efficient for permanent relief. A probe pointed knife, much after the pattern of the Webber's canaliculus knife, but with a longer shank, which should be ductile, is suitable for cutting the membrane. Dr. H. C. Thomas of Philadelphia, exhibited such a knife to the Section at its Detroit meeting in 1892. Its probe point can be pressed through the constricting membrane and the knife made to follow, enlarging the opening by incision. By slightly turning the instrument on its long axis, a second incision can be made on withdrawing it. The process can be repeated in different diameters of the duct as often as desired. After the blood clots are washed away, a Bowman's probe sufficiently large to fit the lumen of the duct snugly should be inserted and allowed to remain for half an hour. When withdrawn the duct should be washed again with a boric acid solution. On the second day the probe may again be introduced and allowed to remain for half an hour. This will in some instances suffice to effect a cure, but the duct should be subjected to occasional inspection by syringing or gentle probing, in order to anticipate any tendency to recurrence. This class of cases have however, in my experience been comparatively rare.

The cases where the obstruction is found in some portion of the bony duct have been far more numerous than any other variety, the next in frequency being located at the inferior punctum or in the canaliculus. Statistics on this point however, as far as I know, are wanting. The obstruction in the nasal duct is as a rule due to a more or less extended narrowing of the lumen of the duct by a thickening of the soft tissues which line its bony walls. The readiness with which, in some individuals, the duct may be entirely closed or its caliber so diminished as to obstruct the flow of tears, will be made manifest by any study of numerous dried or frozen preparations of the bony duct. Such a study reveals great variety in the size and contour of its walls. The irregularities in the surface of the osseous walls of the nasal duct in many individuals obviously render them especially liable to its ready obstruction from even a slight thickening of the lining membrane. While the duct may be large and even abnormally capacious in some parts of its course, forming lake like expansions, in other portions bony projections or irregularities of surface contract its diameters to a narrow channel or a mere slit or produce a tortuosity of its course which explains the difficulty which is often experienced in passing a probe into the nose, even in cases where fluids pass quite readily. The probability of these anatomic peculiarities being present in any case of lachrymal retention should always be borne in mind, and in the adoption of methods of treatment should suggest conservatism in surgical interference. Any violent effort to force a probe through the canal in these cases may very readily cause a traumatism far more serious in its results than the disease we are attempting to cure. If, for example, the canal is tortuous, or if ledges of bone project from its walls the end of the probe is liable to infringe upon the bony surface, and attempts to force it onward are likely to cause a tear in the lining membrane which will allow the probe to pass between the soft tissues and the bone. If these tissues are already the subject of chronic inflammation and thickening, the acute exacerbation caused by the traumatism, and the accumulation of coagulated blood between the bone and mucous membrane lead to increased thickening and a still more complete retention of the tears above the obstruction. I believe that more or less serious injury is often done in this way by converting comparatively simple cases of retention into practically incurable obstruction of the duct. After this accident the most careful manipulation is required in order to prevent its recurrence at every subsequent attempt to probe the duct. When it occurs the grating of the probe against the bone and the subsequent bleeding are sufficient evidence of the accident and no further attempt to pass the probe should be made until the wound has had sufficient time to heal. The duct should, however, be carefully and repeatedly cleansed by warm aseptic and slightly astringent solutions. In long-standing cases the lining membranes of the duct often seem not only thickened, but spongy and friable, so that it is extremely liable to be torn or perforated, especially if too small probes are employed. The size of the probe to be selected is of much importance. The great variation in the size of the osseous duct in different subjects suggests caution at this point. If too large a probe is forced through the passage, not only may the inflamed and friable membranes covering its wall be torn away and driven before the end of the probe, but the fragile projections of bone which encroach upon its lumen may be fractured. This certainly can be necessary in very few instances, if ever, and the results following such violence may be of more serious moment than the original disease. That this accident is probable as the result of using too large probes I demonstrated before the Medical Society of the State of Pennsylvania in 1878. In a group of skulls sent to me by the late Prof. Harrison Allen, there were two in which the nasal ducts were too small to admit the smallest of a series of large aluminum probes, and not one of them would admit the largest probe of the series without a fracture. It may be argued that such a fracture need not be a serious contingent or even that such an enlargement of the bony duct might not be necessary to effect a cure. I can conceive of cases of total obstruction where this might be preferable to obliteration of the lachrymal sac, or to consignment of the patient to life long stillicidium with the ever present liability to recurring attacks of acute blennorrhea, or of phlegmon of the sac, but under all ordinary circumstances such violence should certainly be avoided

The violent methods too frequently pursued in the surgical treatment of lachrymal obstruction, as in cutting operations and in the forcible passing of very large or conical probes, seems to the writer to be based upon a misconception of the *physiologic function* of the parts While the function of the apparatus is to drain the eye of tears, the duct is not in health an open drain pipe through which the tears flow by gravity, but is a delicate pump, the pumping force being the act of winking This delicate function is disturbed or destroyed by any operation, which opens widely the inferior and common canaliculus up to the entrance into the sac, and converts the nasal duct into a permanently broad, open tube It gives ready access for air from the nasal passages to the eye so that in the act of blowing the nose the contents of the duct are forced back into the conjunctival sac The design should be to cause the disappearance by absorption of the thickened or hypertrophied soft tissues which produce the obstruction to the normal exit of the tears In comparatively acute cases, that is to say, when the obstruction is of recent origin the existing pathologic conditions may frequently be cured by the same methods adopted in the treatment of analogous conditions of the conjunctiva, viz , by the use of aseptic washes and mild astringents After dilating the punctum the fine nozzle of a syringe may be introduced and a few drops of a 4 per cent solution of cocain introduced into the sac, and if possible, forced through the nasal duct If the latter is not possible at first it may become so in a few moments by virtue of the shrinking of the swollen and congested tissues through the action of cocain The sac and duct may then be thoroughly washed with a warm saturated solution of boracic acid, or other wash, e g an alkalin antiseptic solution, Dobell's solution, etc After this has been accomplished a few drops of a solution of sulphate of zinc gr ii to f℥i or a silver nitrate solution gr i to f℥i may be introduced The patient should then receive a wash *to be employed at home*, and be instructed to instill it freely into the conjunctival sac, after emptying the lachrymal sac by pressure, and then by rapidly winking, pump it into the sac and again empty it by pressure This can be repeated again and again, three or four times daily between the office visits I have many times, in cases of brief duration, succeeded in effecting a cure by this simple means and have thus avoided any mutilation of the apparatus and caused no pain to my patient A few drops of a solution of cocain prevents pain even from any necessary dilatation of the punctum In chronic cases, however, attended with more or less blennorrhea of the lachrymal sac, with much thickening and sponginess of its walls, and showing well-marked and rigid stricture of the nasal duct, the treatment required is quite different and much more exacting and tedious

In my experience, however, cutting operations are followed by only temporary relief and a subsequent contraction which makes the stricture worse than before, unless a style is introduced and worn until the tube is converted into a patulous drain pipe, through the complete atrophy and change of the tissue by pressure This I think should be avoided, and fortunately in the majority of cases is not necessary In a few instances I have found this the only recourse, but such cases are certainly rare

The object in view in cases of closure through hypertrophy of the lining tissues of the duct is to cause the absorption of the thickened tissue and at the same time to remove the inflammatory conditions which are still present As long as the duct is closed entirely or partially we have to contend with one of these vicious surgical circles It is futile to endeavor to cure the inflammation of the conjunctiva, lachrymal sac and duct as long as the tears are retained It becomes necessary therefore to open the duct so that the tears can flow away This can be temporarily effected, usually by passing a suitable probe through the duct into the nose The method devised by Mr Bowman is the best thus far devised

A probe sufficiently large to pass snugly through the constricted area should be cautiously passed, after the instillation of a few drops of cocain solution, and allowed to remain twenty to thirty minutes The patient soon experiences an increasing sense of pressure and throbbing The attempt to withdraw the probe will usually require more force than was needed for its insertion The duct should then be flooded with a suitable wash, followed by an astringent The theory for such treatment is the gradual absorption of the hypertrophy by pressure of the thickened tissue between the probe and the walls of the duct The absorption is in some instances aided by washing the duct with a weak solution of iodin This solution can be readily made as needed by dropping Lugol's solution of iodin into distilled water, until it assumes a light wine color In many patients the treatment may be repeated with benefit on alternate days, while others require longer intervals of rest That these conservative measures of treatment are successful in the majority of patients I have had abundant opportunity to demonstrate When success is not reached it will be found that some marked anatomic defect is present in the duct itself or that the turgidity of the soft tissues is maintained by pressure through anatomic defects or pathologic conditions in the nose, or, that some constitutional vice is present In such cases *treatment must be addressed to these collateral* conditions before a cure can be expected

In a large group of cases the congested state of the lachrymal drainage system seems to depend upon eye strain due to refraction errors, or abnormalities of ocular balance, the turgescence of the membrane lining the duct being common with that of the caruncles, the conjunctiva and the intraocular membranes I have many times seen the lachrymal retention disappear with the cure of the intraocular conditions by treatment and the use of correcting glasses without *any treatment addressed directly to the lachrymal* apparatus

---

COLPOPERINEORRHAPHY AND THE STRUCTURES INVOLVED

DEDICATED TO DR THOMAS ADDIS EMMET AND MR LAWSON TAIT
IN RECOGNITION OF THEIR LABORS IN THE SURGERY
OF THE PERINEUM

BY BYRON ROBINSON, B S , M D
CHICAGO ILL

Continued from page 650

In 1887 Dr Hadra of Texas contributed some valuable articles on the subject of perineorrhaphy He suggested vivisection of the posterior vaginal wall for colporrhaphy, as is done in anterior colporrhaphy Since 1880, the laborers in the field are legion Gradually the operation of perineorrhaphy was modified from Paré, Baker-Brown Dieffenbach, Langenbeck and Simon to Tait and Emmet The modification consisted in denuding not only the perineal tears, but also denuding higher up in the posterior vaginal wall Hildebrandt especially carried the denudation well up into the posterior vaginal wall

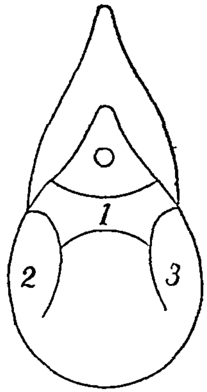

Fig 18A —Emmet's operation (elytrorrhaphy posterior) for prolapse 1 and 2 show the lines of union of denuded surfaces in the vaginal sulci on each side of the vaginal column 3 which still remains

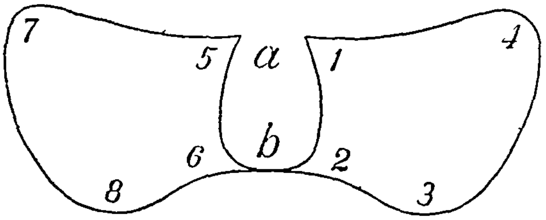

Fig 18B —Staude's operation (elytrorrhaphy posterior) for prolapse 1 2 3, 4, and 5, 6 7, 8, represent the denuded vaginal sulci *a b* shows the intact column, which is utilized in coaptation and fixation of the denuded surfaces The principle of saving and utilizing the column is the same as in Martin's and Emmet's operation

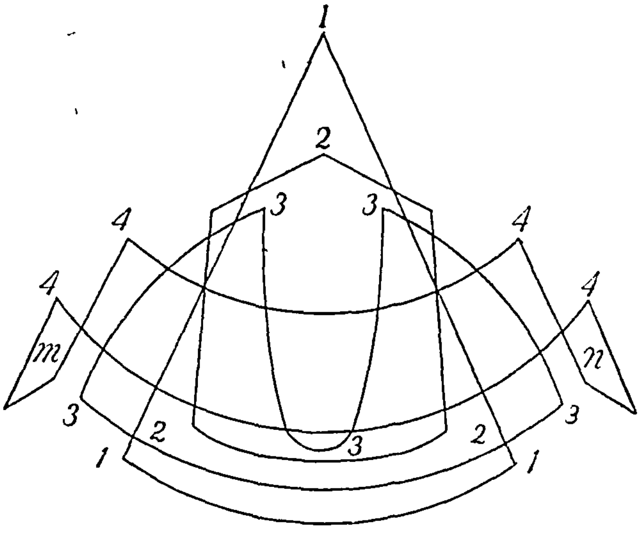

Fig 18C —Various shapes of the denudation in posterior elytror rhaphy represented by superimposed diagrams 1 1 1 Hegar's 2 2 2 Simon's 3 3, 3 Bischoff s, 4, 4 4 *m*, *n* Winckel's *Observe that Bischoff* saves the column

As regards suture material, Sims, Thomas, Emmet and others worked out the application of metallic wire to plastic labors on the perineum during the past thirty years The modern tendency is to use silkworm gut as a non-absorbable suture This may be left weeks in a wound, and acts as a splint in coapting the surfaces It is easy to remove To Dr T A Emmet is due the credit of introducing a method of perineorrhaphy which, until recently, was the one generally practiced in America In 1883 Dr Emmet published a new method, or rather a modification of his old operation Dr Emmet denudes the sulci on each side of the vagina and extends the perineum forward His operation is intended to repair perineal fascia and muscles Dr Emmet holds that loss of support following laceration is not due to injury of the perineal body The loss of support after childbirth, he claims is due to rupture of perineal muscles and fascia Dr Emmet's operation is difficult to make clear by description, but it consists in lateral denudation wholly within the vagina to such an extent that when the sutures introduced are drawn tight, the excess or slack in the posterior vaginal wall disappears The ostium vaginæ is not interfered with by any special denudation The claim of his operation is that discomfort disappears immediately after, and also that the posterior vaginal wall is brought in proper position and relation to the anterior wall, as it is in the normal condition The view contained in the surgical procedure is that the perineal body is insignificant in support, and that laceration of it alone impairs but little the integrity of the genital supports But the tearing or excessive stretching of the perineal muscles and fascia at their attachments to the genitals quickly disturbs the delicate balance of the pelvic organs There is one point against Dr Emmet's operation, and that is the relatively blind method of introducing the higher sutures In other words, the deep layers of the lacerated pelvic fascia may not be included in the sutures with any degree of certainty Dr Gillwyly added the idea that Dr Emmet's operation would be improved by denuding the posterior vaginal wall a considerable distance and then continuing the denudation well up into the posterior vaginal sulci This method, however, sacrifices a larger amount of posterior vaginal wall

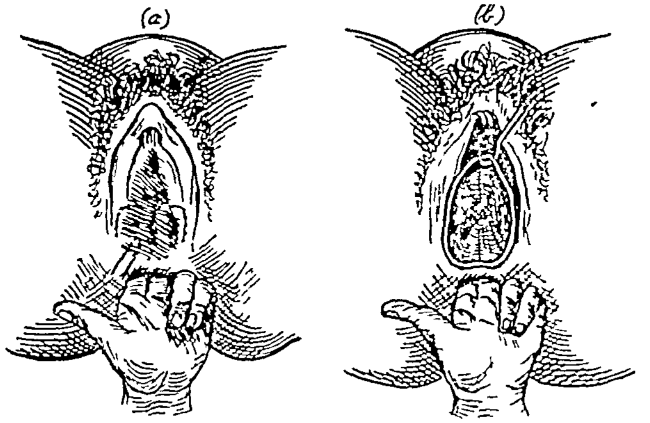

Fig 19 *a* and *b* —Dr Jenks' method (flap) of perineorrhaphy The flap splitting is executed with two fingers in the rectum, and a scalpel In *a* the flap is marked out by a dotted line in *b* the flap is completed ready for suturing

About 1872 Mr Lawson Tait of Birmingham, England, began to introduce a method of perineorrhaphy known as the flap method It differed from all others in that he used elbow scissors and introduced the very deep sutures without penetrating the skin or mucous membrane It involved no loss of tissue The direction for doing the Tait operation is to resplit the old cicatrix It is modified according to the condition of the case, as one may produce anterior and posterior cuts Tait's flap perineorrhaphy is now quite generally practiced I have not attempted to give all known historic methods of perineorrhaphy, but simply the chief ones out of which has been built the modern operation

GENERAL INDICATIONS FOR PERINEORRHAPHY

1 To restore rectal and vaginal functions

2 To restore pelvic fasciæ and muscles Normal fascia is required for normal circulation

3 To restore the normal relation and support of the posterior wall (colporrhaphy posterior) The posterior vaginal wall sustains the anterior vaginal wall and bladder

4 To provide as much support for the pelvic organs as the restoration of the perineal body will afford

5 To remove the neurasthenic conditions, to relieve the innumerable nervous associations, in short to relieve mental and physical disturbances

6 To repair and check sacropubic hernia

7 To narrow relaxed pelvic outlet

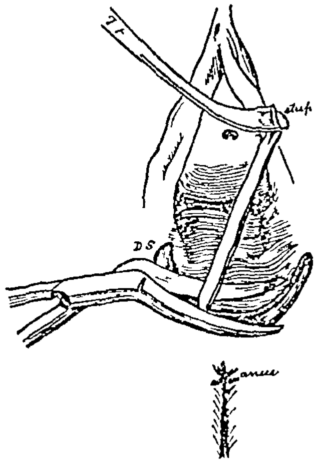

Fig 20 —Method of denudation of vaginal strips, with curved scissors from one side of the vagina to the other, as suggested by Dr Skene

The pelvic floor is closed from behind forward by the pyriformis with its thin, delicate fascia, the firm sacrorectal ligaments, the coccygeus with its moderately strong fascia, the levator ani muscle with its levator ani fascia superior and inferior, a strong double fibrous protective muscular sheath, and also the triangular ligament, a powerful layer of fibrous tissue The coccygeus with its fascia, the levator ani with its double fascia and the triangular ligament practically constitute the pelvic floor and seem to separate the pelvic cavity from the perineum These are essential structures in colpoperineorrhaphy The levator ani fascia (both layers) pass from the side of the pelvis to the viscera, firmly attaching themselves to every pelvic organ, forming the strong, fibrous expansions known as ligaments, which serve to hold the pelvic viscera in definite fixed relations In perineorrhaphy, success depends on the restoration of these vital supports, a significant anatomic fact in pelvic pathology is that the blood-vessels lie superior to the pelvic fascia and the nerves inferior to it The blood-vessels which arrive in the perineal region pierce the pelvic fascia and pass chiefly out of the great sacrosciatic notch

The levator ani fascia, superior and inferior, is an important structure to limit infection It separates the ischiorectal fossa from the pelvic cavity proper where so much loose tissue exists The levator ani fascia is pierced by vessels and nerves, and these vessels and nerves are surrounded by lymphatic sheaths which are a source or path by which the infection may travel from the pelvis to the ischiorectal fossa, and vice versa In perineorrhaphy the levator ani fascia, superior and inferior, is incised The operation which is performed for the restoration of the perineum exists under different names It may be termed perineorrhaphy, perineo-vaginal restoration, perineal extension, perineauxesis, or the flap method However, I think the best name is colpoperineorrhaphy Colpoperineorrhaphy is an operation to restore the integrity of the supports of the sexual organs. These supports include those of the peritoneum and vaginal sphincter apparatus

The perineal body is situated between the lower end of the vagina and the rectum Difference of opinion still prevails as to the utility of the perineal body in the economy of the female genitals, but, from many dissections and considerable work on the subject, I claim the following functions for the perineal body

1 It sustains the lower ends of the anterior rectal wall and posterior vaginal wall

2 It supports and directs the discharging end of the vagina forward, aided by the triangular ligaments and levator ani

3 It supports and directs the discharging end of the rectum backward, the rectum is directed backward by the levator ani muscle

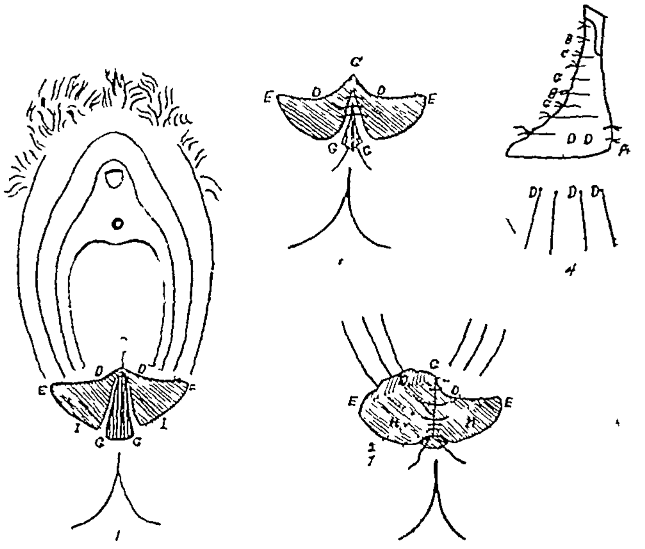

Fig 21 —(After Pozzi) LeFort s (1889) method which is similar to Demarquay's (1864 1875) and Richert s An incision is made in the vagina at the point C in the median line down to the rectum, then an incision is made along the line C D E another line C G is carried along the rectal wall but not into the rectal mucosa another line joins it by means of E I G this makes a distinct triangle H (seen in No 3) the cicatricial tissue is removed from the triangle H and also the portion of the vaginal wall, marked D is seized and dissected from the rectal the space denuded is D and H (No 3) the sutures are introduced as shown in Nos 2 and 3 The disposition of the sutures are noted in No 4 The operation is a partial flap method, but *too complicated for ordinary practice*

4 It not only keeps the discharging ends of the rectum and vagina widely apart, but it gives both a support in a curved direction at their termination, thus affording mechanical advantages for maintaining closure of both apertures and preventing the easy escape of the contents of either canal The wide divergence of the two canals avoids mingling of the secretions and consequent irritation from decomposition The backward hook of the rectum and the forward hook of the vagina is an important factor in support, and prevents gaping The perineum is the skin between anus and vagina The perineal body consists of skin, fat, muscles, fascia, elastic tissue, and connective tissue The perineal body as a support in itself for the genital organs has been much overestimated

5 It serves as the point of union of four muscles: the levator ani, the sphincter ani, the bulbo-caverno-

sus, and the transversus perinei. It serves also as a point of union of the various fasciæ.

6. It acts as a partial support of the pelvic floor.

7. It strengthens a tried point in labor.

8. Laceration of the perineum to any considerable extent destroys the nice balance between anatomic structure and physiologic function in the female genitals.

The object of perineorrhaphy is: To restore partial ruptures, to restore rectal functions after complete ruptures, to prevent prolapse of the pubic segment of the pelvic floor.

The methods of performing perineorrhaphy are denudation with fixed coaptation, and the flap method. The etiologic factors of lacerations are labor, coitus and trauma. Partial laceration of the perineum may be accompanied by vulvar patency, increased vaginal secretions, irritability of parts, pathologic condition of nerve structure, neuralgic or neurotic conditions induced by long continued local lesions, descent (distentions) of anterior rectal wall, posterior vaginal wall, and the uterus. Complete laceration of the perineum may be accompanied by vulvar and anal patency, increased vaginal and rectal secretions, incontinence of bowel contents and occasionally of bladder contents, irritability and disease of the surrounding parts from the abnormal secretions, neuralgic and neurosal conditions from changes in nerve structures, melancholia (neurasthenia), relaxation of the displaceable segment of the pelvic floor and consequent prolapse or hernia of the pubic segment. The result may be severe congestions from a disturbance of the fascia which holds the blood-vessels in relation. If the blood-vessels become distorted in their bed, disturbed circulation results.

In discussing the operation for colopermeorrhaphy by Dr. Thomas Addis Emmet and Mr. Lawson Tait, I shall consider these both founded on anatomic principles, both practical and successful operations, and both arriving at the same end by different methods. However, since I can accomplish by a flap method exactly what Dr. Emmet accomplishes by denudation, I have preferred to follow the flap procedure. I have employed the flap method for over six years, comprising over one hundred operations performed for almost all kinds of perineal laceration and uterine prolapse. In one case the uterus was completely prolapsed for fourteen years. Another case with laceration extending up the rectum the length of the index finger of thirty four years' standing was operated successfully after three previous denuding operations. A third case was lacerated up the rectum for four inches, of twenty-eight years' standing, and had passed through three unsuccessful operations. One of twenty-seven years' standing, with three-inch rectal laceration, and one very different case of seven years' standing, with several unsuccessful operations by well known gynecologists were operated on with perfect success. In these cases of long standing, atrophy was so far advanced from limited blood supply and non use that it required extensive flaps in order to secure tissue for a perineal body. To show that the perineal body is not significant in uterine support several of those patients continued for over twenty seven years with laceration several inches up the rectum, with scarcely a symptom of uterine prolapse.

It will be observed from even a superficial experience that the patient should be properly prepared for colpoperineorrhaphy. If the patient have a long, pointed cervix, which acts like a conic wedge being driven downward at every breath or increase of intra-abdominal pressure, it will constantly dilate the vaginal sphincter apparatus and should be amputated. The amputation may produce involution of the uterus. A long, pointed, conical cervix generally has behind it a retroverted uterus which precedes prolapse.

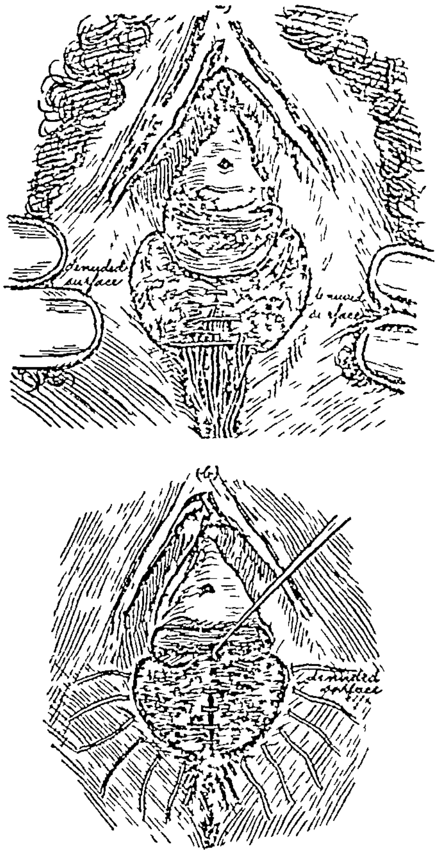

Fig. 22 *a* and *b*.—Dr. Skene's method of denudation and suturing the rectum.

Again, if there is a cystocele the patient should be prepared by an anterior colporrhaphy. It may be amputation of the cervix and anterior colporrhaphy can be done at the same sitting and anesthesia as the flap splitting colpoperineorrhaphy. We frequently perform colporrhaphy and colpoperineorrhaphy at the same time. To require cervical amputation is rather rare, but if there be a retroverted uterus with pointed cervix it should be amputated and turned backward against the sacrum. In short we must imitate nature as much as possible to secure success. All hernia is the same, it is due to the destruction of normal valves and the straightening out of oblique canals. Hence in sacropubic hernia the normal obliquity of the vaginal canal must be restored. Colpoperineorrhaphy restores the posterior vaginal wall and anterior colporrhaphy restores the anterior vaginal wall. This is not often needed if the colpoperineorraphy be thoroughly performed. Prolapse is prevented by perineorrhaphy, elytrorrhaphy, episiorrhaphy (or some abdominal operation). Prolapse may be considered as a downward displacement of the pubic segment of the pelvic floor; the sacral segment of the pelvic floor shares in it by a yielding of some of its parts. There are so many varied opinions as to the etiology of prolapse that one can safely say the subject is not fully settled. In my opinion [illegible] due [illegible] Hart and Barbour for [illegible] on the structural anatomy of the pelvic floor After considerable careful dissection I feel quite sure that many previous views must be changed, but it is hopeful when the closest and most continued students of the pelvic floor come nearly to the same conclusion The subject of prolapse, I think, should be studied out anatomically and clinically The field of investigation is still large As time goes on the uterus itself will get less attention and the pelvic floor more The subject of relaxation and submucous laceration will be more studied Relaxation of the whole pelvic floor, due to repeated labors, infectious processes and anatomic lesions will be found to be a large factor in prolapse Insufficiency of perineal support should not be lost sight of, and the sphincter apparatus of the pelvic floor will be more studied From dissection one would at once conclude that the levator ani fascia and the triangular ligament were the main supports in the pelvic floor, and the relations of other supports must be considered Dissection is the only intelligible way to understand the subject For example, dissection of quite a number of bodies has thoroughly explained, in my mind, the conflicting views of anatomists and gynecologists as to the position of the uterus As a gynecologist I have examined several thousand women, and I am sure that the uterus leans forward in the normal condition Repeated examination on the back and while standing will prove that slight anteversion is the normal position of the uterus Now, the anatomist has often insisted that normally the position of the uterus is in the hollow of the sacrum I have repeatedly found in the dead subject that the uterus is in the hollow of the sacrum, precisely as the anatomist has described Both gynecologist and anatomist are correct In the living woman the normal position of the uterus is that of anteversion In the dead woman in dorsal decubitis the uterus generally lies in the hollow of the sacrum In just such a manner arise the differences of opinion relative to prolapse, which can only be cleared up by careful personal anatomic and clinical investigation A comparison of different causes will soon let in the light

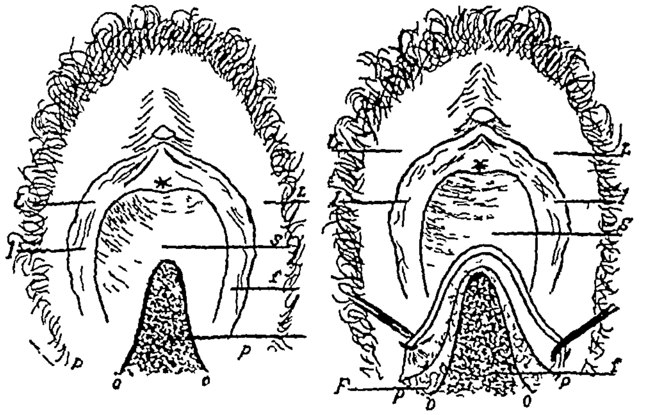

Fig 23 *a* and *b* —Fritsch Walzberg method The figure is according to Pozzi The laceration extends into the rectum S rectovaginal septum, F, rectovaginal septum lacerated, P, perineum In *b* the rectovaginal is split

Though the peritoneal supports of the uterus be deficient they can be put at rest and finally cured by carefully planned operations on the vaginal sphincter apparatus All primary uterus supports are attached to the neck of the uterus and before the uterus shows such signs of hernia the supports attached to the neck must be definitely elongated Doubtless the uterine supports are frequently elongated by infective processes and hence a rest by repairing and fortifying the sphincter vaginal apparatus will result in restoration Especially is this true in certain forms of retroversion If the uterus remains in its normal position (i e, perfectly movable) no retroversion and consequent prolapse will arise In chronic infection processes the pelvic organs at times swell, soften, become edematous, ending in a form of hypertrophy from static congestion I have frequently observed this slow repeated process in the clinics

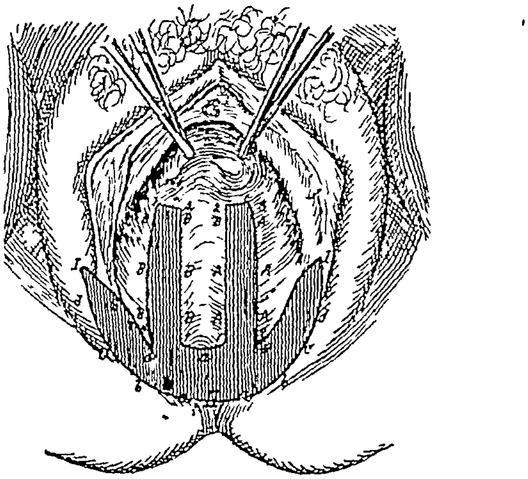

Fig 21 —(After Hegar and Kaltenbach) Bischoff's method of colpoperineorrhaphy He denudes high up on each side of the posterior median vaginal column B, B A A This method partially foreshadowed Emmet's operation Note the butterfly wings 1, 2, 3 d, d Bischoff saved the posterior vaginal

ETIOLOGY OF PROLAPSE

1 Insufficiency of sphincter apparatus *a*, levator ani muscle, *b*, triangular ligament (anterior posterior layers and fascia of Colles), *c*, levator ani fascia, superior and inferior, *d*, perineum (composed of levator ani, bulbo-cavernosus, transversus perinei and sphincter ani ischeo perineal ligaments), *e*, vaginal walls, *f*, urethrovaginal septum, *g*, recto-vaginal septum, *h*, muscular and elastic tissue on lower third of vagina

2 Insufficiency of peritoneal supports *a*, uterosacral ligaments, *b*, round ligaments, *c*, broad ligaments *d*, vesico-uterine ligaments, *e*, perineum, *f*, elongated cervix

3 Intra-abdominal pressure in increased or applied in abnormal directions

4 Relaxation of anterior segment of pelvic floor *a*, repeated labor *b*, submucous, concealed facial lacerations, *c*, subinvolution of pelvic floor and organs

5 Weight of uterus, which affords surface for intra-abdominal pressure

OPERATIONS FOR PROLAPSE

1 Tait's flap operation (and extension) of perineum
2 Perineo-episiorrhaphy
3 Elytro perineorrhaphy
4 Elytrorrhaphy
5 Amputation of cervix
6 Shortening of round ligaments (Alexander-Adams)
7 Shortening of broad ligaments
8 Fixation of the uterus to the abdominal wall (hysteropexy)
9 Schucking's operation
10 Herrick's operation
11 Mackenroat's operation

The operations for prolapse have been as varied as the views of its cases Operators have attacked the uterus, vagina, vulva and uterine ligaments to accomplish their purpose The pioneer idea in prolapse was to close up the vulva so that the uterus could not escape Thus we have the early episiorrhaphy of Fricke and Kuchler But surgeons soon saw that simply closing up the vulva was like attempting to board up Mount Vesuvius The forces at work were not at the vulva but deep in the interior Then came the operations on the perineum with all their variety, from Guillenneau's successful case through Dieffenbach, Langenbeck, Simon and Sims, to the modern flap operation Finally to episiorrhaphy and perineorrhaphy were added operations on the wall of the vagina (colporrhaphy and elytrorrhaphy) Elytrorrhaphy has been quite a successful addition to gynecology, but it is a denudation operation and hence destroys valuable tissue I have observed that the European operators attempt to save anterior and posterior columns of the vagina Men see in the column a valuable piece of supporting tissue, and some of them, like Martin, try to save it Dr Emmet has worked along the same line and his operation is one of the most useful of its kind and if mastered and done thoroughly is successful In it he has combined the best principles of the denudation method It saves the columns and denudes the areas of least resistance His idea of supporting the pelvic floor is certainly correct If the flap splitting method could be made use of in this operation it would be a marked step in advance The vulvar and vaginal operation of denudation should be superseded by the flap-extension method, which might be called perineo episiorrhaphy It is done with no loss of tissue and can be carried right up to the urethra The amount of flap and consequent barrier of tissue built up at the vulva will depend on the depth of the scissors clip and the amount of exposed tissue, and also much on the manner of suturing the surfaces to be coapted The flap-extension method will form one of the best supports for prolapse The objections against the Alexander-Adams operation are 1 Unsatisfactory reports and the bias in selecting cases for the operation 2 In quite a number of bodies the round ligaments can not be found In many cases which I investigated no muscular ligaments could be discovered until one got inside the internal abdominal ring 3 No operator can tell in which cases the difficulty will occur 4 The danger of opening the peritoneum 5 The round ligaments are insufficient for a main uterine support 6 Hernia may follow the operation 7 In case of uterine adhesions the ligaments will not raise and support the uterus Results will not be permanent The round ligaments will gradually yield to uterine weight, especially if there be an enlarged uterus, as is often the case in prolapse

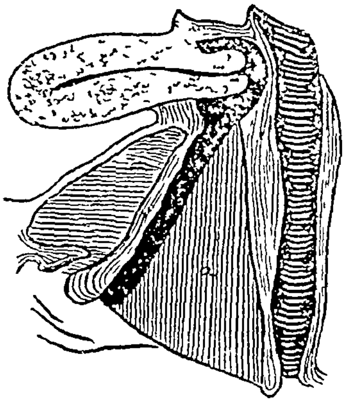

Fig 25 —(A Martin) Colpoperineorrhaphy posterior according to Hegar a, is the newly built perineum

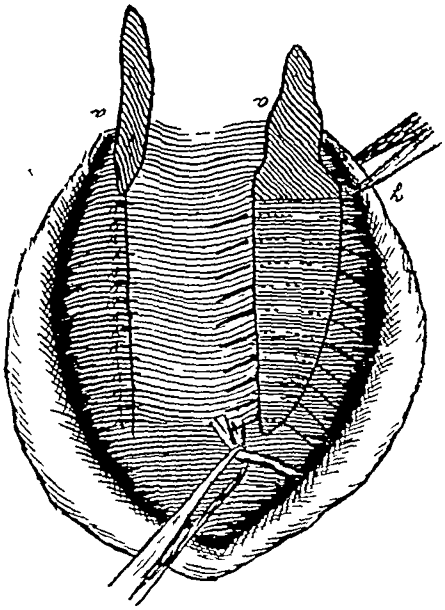

Fig 26 —Colpoperineorrhaphy after A Martin He styles it elytrorrhaphia duplex lateralis The first step is to resect denude the two vaginal flaps the left side is freshened and sutured the right side freshened with the sutured but not tied a, a the denuded vaginal flaps

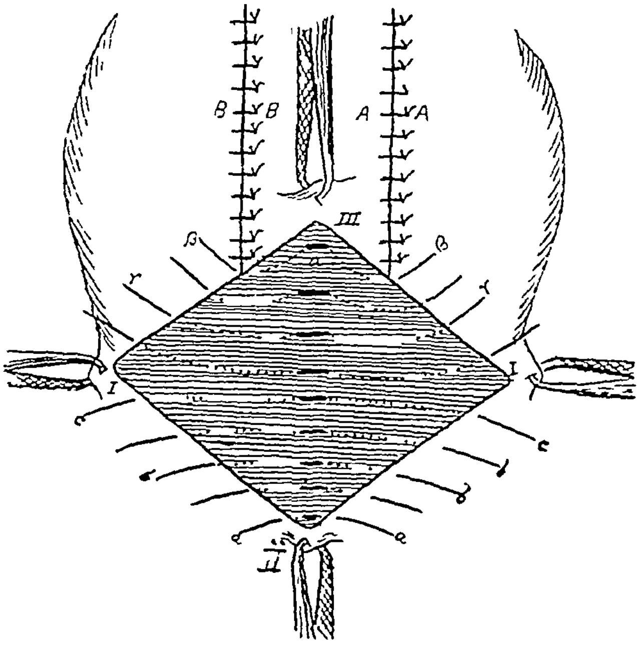

Fig 27 —Second step in A Martin's colpoperineorrhaphy He calls it perineauxesis a and b show the lines of the vaginal denudations sutured (elytrorrhaphy) The diamond shaped space 1 2 3 is the perineorrhaphy following the colporrhaphy posterior The letters indicate the sutures

Some of the above objections may be modified The Alexander-Adams operation is an excellent one in selected cases in retroversion without adhesions it will frequently be of great utility But it is here mentioned as an accessory operation to colpoperineorrhaphy Shortening the broad ligaments is of questionable value Hysteropexy, or the fixation of a movable organ is against all physiologic principles

Schucking's operation for prolapse is not yet established, and it seems the bladder would be in great danger of being wounded during the operation Herrick s operation of attaching the cervix to the posterior vaginal wall has made [illegible] we have not yet learned h [illegible] cro uterine ligaments in prolapse Such operations are but accessions to colpoperineorrhaphy The advantages of the flap operation are

1 The ease and simplicity of its performance

2 It wastes no tissue, if it fails the patient is no worse off than before the operation, whereas the failure of a denudation operation leaves serious defects

3 It is the only operation that restores in a natural method the perineal body The linear cicatrix is split and sutured in the opposite direction Dr Emmet's operation unites the perineal wound artificially by uniting tissues not previously involved

4 It withstands subsequent labors, several of our operations have withstood perfectly subsequent labors Mr Tait informed me of the same fact in many of his operations

5 The sutures are not passed through skin or mucous membrane, and therefore are not so liable to suppurate or produce pain

6 The certainty of healing

7 The flap operation secures in the easiest and most convenient manner the widest possible surface for coaptation and healing of the fasciæ and adjacent tissues in the median line for support

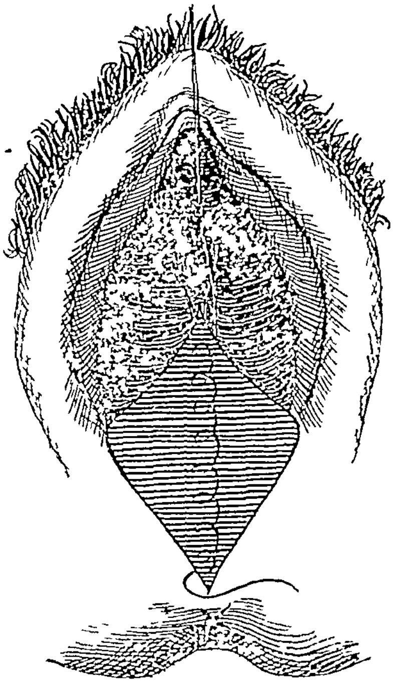

Fig 28 —Martin's operation with a continuous catgut suture (etagennaht) It is a continuous buried suture

8 The pain after the operation, in my experience, is less than after the denudation operation

9 Tait's flap operation can be practiced successfully where the repeated denudation operation can not be performed because of loss of tissue and excess of tension

10 The short time required to do Tait's flap operation minimizes shock

11 The resulting cicatrix is in its natural location and linear, and will thus cause less peripheral nervous disturbances

12 The stitches leave no cicatrices and therefore will cause no irritation One can observe the most practical and best observers trying to save the column and trying to perform denudations in the vaginal sulci The superiority of Tait's flap operation is that it saves all tissue and builds a natural perineum in a natural location, and thus subserves natural forces according to nature's original law, and anatomic structures are not much violated by cicatrices and cicatricial contraction

A fact not generally appreciated is the neurosis, the neurasthenic condition produced by perineal lacerations The visible wound is not always commensurate with the suffering There may be a visible wound an infection atrium, or simply an over-stretching of muscle and fascia, which stretches and traumatizes the peripheral nerves, producing nervous irritation The fascial planes which hold the blood-vessels in distinct relation, are so damaged that congestion and decongestion of the pelvis frequently arise Healthy veins should be spiral and uniform in caliber The laceration of the pelvic fascia allows the veins to straighten out and become irregularly dilated This straightening out and dilatation produces not only blood and lymph congestion, but peripheral nerve pressure The frequent pelvic congestions and decongestion from deficient blood-vessel's support, produce conditions which favor the development of pathogenic microbes in the genital mucosa The gynecologist sees many patients with neurotic phenomena which can only be attributed to perineal lacerations and defects

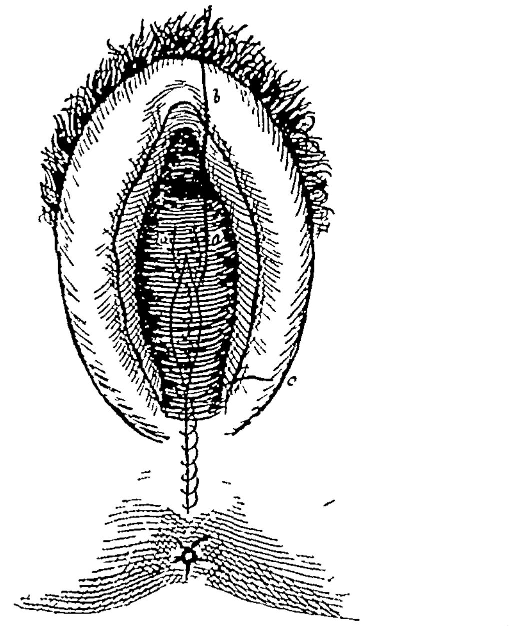

Fig 29 —Martin's operation with buried catgut The upper part (elytrorrhaphy) posterior colporrhaphy the lower part (perineauxesis) perineorrhaphy b, the upper end of thread c lower end of the catgut

When the sutures are tied the newly formed perineum will look enormously longer, but it will soon shrink to the natural condition After some experience one can do the flap operation so that on healing the linear cicatrix will resemble the old raphe so closely that one can scarcely tell after six months that an operation has been performed

For cystocele the flap operation can also be performed The flap method is alike applicable to partial and complete perineal laceration The operation is best demonstrated on complete lacerations

(To be continued)

Formalin for Insect Bites —As the subject of insect stings is mentioned in a recent annotation, may we point out that "formalin" (recommended some time ago for mosquito bites in one of the medical journals by a Zanzibar correspondent) is an excellent remedy for the irritation produced by the stings of all insects? The "bite" is touched with the moistened stopper of the "formalin" bottle and as soon as it begins to smart the excess is wiped off, relief is almost instantaneous

SOCIETY PROCEEDINGS

American Association of Obstetricians and Gynecologists

Eleventh Annual Meeting held in Pittsburg, Pa, Sept 20, 21 and 22, 1898

FIRST DAY—MORNING SESSION

The association met in the assembly hall of the Monongahela House and was called to order by the president, Dr **Charles A L Reed** of Cincinnati Ohio, at 10 A M

Dr **John Milton Duff** of Pittsburg welcomed the association on behalf of the local medical profession Lieutenant-Governor **Walter Lyon** followed with a brief but very eloquent address of welcome on behalf of the citizens of Pittsburg and of the State President **Reed**, in behalf of the association, responded to these remarks of welcome in a very concise but graceful speech

Following the preliminary exercises came the first paper of the scientific session, by Dr **Frederick Blume** of Allegheny, Pa, entitled

SOME OF THE COMPLICATIONS FOLLOWING VAGINAL HYSTERO SALPINGO OOPHORECTOMY IN PELVIC SUPPURATION, WITH REMARKS ON THE OBJECTIONS TO THIS OPERATION

He said a perusal of the literature of the past few years proved that vaginal hysterectomy had made its way here and abroad Its condemnation upon therapeutic grounds had decidedly diminished Its advantages were too plain to permit of being longer ignored Men who, in the beginning, strongly objected or opposed this mutilating operation, as some were fond of styling it, had changed their opinions Guided by the experience of others, they had adopted this method and confirmed the assertions of its advocates that it was a conservative operation in the broadest sense of the word—a procedure which, though sacrificing the uterus, conserved the life of the patient even under circumstances where the suprapubic route would mean certain death The propriety of removing the uterus in suppurative disease of the appendages had been questioned ever since Péan introduced vaginal hysterectomy Briefly stated, the chief objections were 1, the uterus was not a useless organ after the ablation of the appendages, and should not be sacrificed unless seriously diseased, 2, vaginal hysterectomy was an incomplete procedure followed by serious complication and was not curative The disposition to preserve the uterus during the child bearing age in women with healthy tubes and ovaries, or in unilateral suppurative pelvic disease, could well be understood, but why this organ should not be removed as the initial step of a life saving operation, when the ablation of both appendages became a necessity, was beyond comprehension The assertion that the uterus without the appendages was still an important organ, that its functions had not ceased with the artificial induction of the menopause must be rejected as untenable in the light of present knowledge The arguments that after the extirpation of the uterus the nervous phenomena were more pronounced than when the appendages were left alone, had strongly influenced many surgeons against vaginal hysterectomy Careful investigation, however, had shown that these arguments could not be verified Mainzer, in a report of 200 vaginal hysterectomies for chronic inflammation of the adnexa, performed in Landau's clinic, had arrived at the conclusion that there is less disturbance of the nervous system after the radical operation than after salpingo oöphorectomy alone He further states that the age of the patient bore no relation to the presence or absence of these nervous symptoms Dr Blume does not confirm the view that the removal of the uterus increases the nervous disturbances incidental to the menopause, and he is inclined to believe that this view is based upon the complaints of neurotic women As to the sexual passion, his patients with but one exception state that they have as much sexual appetite now as at any time before operation Two of them, young widows, who married a year after the operation, informed him repeatedly that they were more passionate and enjoyed sexual intercourse more than ever The mortality of vaginal hysterectomy was considerably less than that of the abdominal operation There was, however, a diversity of opinion as to the ultimate results of the vaginal procedure The essayist does not resort to the vaginal method in those cases in which there is a possibility of saving one tube and ovary, i e, in cases of unilateral suppuration even when due to gonorrhea He is not yet convinced that both appendages must be sacrificed, far less the uterus, when gonorrheal infection is limited to one tube and ovary His personal experience with vaginal hysterectomy for pelvic suppuration is limited to forty two cases operated during the years 1895 to September, 1898 This series, though small in number, was quite interesting on account of the extent and the gravity of the pathologic changes Of the forty two patients, eighteen belonged to that desperate class which, if treated by the abdominal route, were either left unfinished or, according to the statements of prominent operators, had a death rate of 25 to 30 per cent in the hands of the most skillful surgeons The pelvic organs were agglutinated into one mass and could not be distinguished by vaginal or rectal examination In some instances these masses reached half way to the umbilicus, while in others the peritoneal cavity was less involved and they extended downward into the vagina, pushing the uterus against the symphysis pubis and compressing the rectum to such an extent that an ordinary rectal tube could not be passed without difficulty The lesions of the remaining twenty four patients were not quite so extensive, yet in every instance both appendages were so far involved that a conservative operation was out of question Complications occurred in three cases

Dr **Joseph Price** of Philadelphia said that the sexual appetite of women, alluded to by the essayist, following a variety of operative procedures, was in many instances improved rather than impaired It was rare for a woman to complain of impaired sexual appetite after a supravaginal hysterectomy Age, however, should be considered in discussing the nervous phenomena incident to a normal or precipitate menopause He advocates the abdominal route, saying that the vaginal method was an incomplete one The latter method favored bowel obstruction Of ten vaginal hysterectomies performed by Coe in his early work, there were two deaths from intestinal obstruction

Dr **Edwin Ricketts** of Cincinnati, cited an instructive case in which it became necessary to resort to the combined method He spoke in favor of the vaginal route in some cases, but not in all instances, for pus in the pelvis

Dr **Rufus B Hall** of Cincinnati was willing to admit that there were cases that could be dealt with by vaginal section and drainage, but the field for this operation was limited In cases in which there were dense adhesions to viscera, good, complete work could not be effected by the vagina Experience had taught him that if a patient was under 35 years of age and the uterus was removed by an abdominal operation and the cervix was left, she suffered less from reflex disturbances than she did when the uterus was left

Dr **Charles Greene Cumston** of Boston said that suppurative conditions within the pelvis demanded different treatment, according to their situation, the number of foci, their size and nature, and in making the diagnosis and considering the choice of operation, all of these things should be considered, whether the case be suitable for the vaginal or abdominal route In most cases of pus in the pelvis, speaking in a broad sense, posterior colpotomy was a trifling operation, yet a conservative one It could be performed in chronic, purulent cases of the female pelvic organs and in acute suppurations where it would be dangerous to do either abdominal or vaginal hysterectomy

Dr **James F W Ross** of Toronto said that at the Montreal meeting of the British Medical Association vaginal hysterectomy for cancer was discussed, and his experience agrees with that of Price, that this operation for carcinoma, no matter how early it was done was not satisfactory High amputation of the cervix after the method of Byrne had been satisfactory in his hands

Dr **L H Dunning** of Indianapolis remarked that the character of the suppurative products encountered by the surgeon called for different lines of procedure In the cases described by the essayist, in which the pus accumulations were exceedingly large extending as high as the umbilicus, fixed, and extending down into the vagina, it had been his practice for the last ten years—and he saw no reason to change it—to do vaginal section In such instances where vaginal hysterectomy was done it was exceedingly difficult, if not impossible, to remove the pus sac, He had operated on fifty cases of the kind described, by vaginal incision Of this number four returned for subsequent operation All but one had made primary recoveries

Dr **B Sherwood Dunn** of Boston believes the perfection of technique of hysterectomy by the vaginal route exceeds in difficulty that by the abdomen to a great degree The complications following the vaginal route exceeded those of the abdominal method The danger to the ureters the bowel and post operative hemorrhage were very much greater by the vaginal than they were by the abdominal route He restricted vaginal hysterectomy to a few selected cases where [illegible] of death of his patients by the suprapubic [illegible] operation was difficult, and in many ins lowed by a second operative procedure through the abdominal wall

Dr W E B DAVIS of Birmingham holds that vaginal incision and drainage has a large field There was a great deal of difference between operating upon old gonorrheal cases and upon fresh ones Unquestionably all the cases following the puerperal state, where the surgeon can place his finger upon the side or behind the uterus, could be dealt with better by the vaginal route The surgeon made a mistake when he opened the abdomen to deal with this class of cases, when vaginal incision and drainage was such a simple procedure While a few cases would return for secondary operations, the surgeon should be willing to give young women several operations, if necessary, to save important organs

Dr C A L REED of Cincinnati formerly resorted to the vaginal route and, after trying it carefully and conscientiously in many cases, he had practically abandoned it and had returned to the abdominal incision He had found, however, a class of cases in which hysterectomy was a very important concomitant in the course of treatment, but even in these he does not remove the uterus per vaginam

The paper was further discussed by Drs A B Miller of Syracuse, and J Henry Carstens of Detroit

FIRST DAY—AFTERNOON SESSION

Dr D. TOD GILLIAM of Columbus, Ohio, contributed a paper entitled

OPERATIVE TECHNIQUE FOR INTRALIGAMENTOUS OVARIAN CYSTOMA

Prior to the enucleation method of Miner, the surgical treatment of these cases was crude and incomplete Miner's method marked a new epoch and will ever remain the foundation principle of their surgical treatment It was, however, attended with so much difficulty and danger as to greatly abridge its usefulness The chief danger was from hemorrhage, which was oftentimes fearful and not infrequently fatal Other, and by no means unimportant, dangers came from injuries to important pelvic structures while conducting a hurried and blind dissection There was a crying need for something better The essential factors of the ideal operation are 1, tapping, to reduce the volume of the cyst and to open the way for hemostasis, 2, ligating the supply vessels to control hemorrhage, 3, enucleation along the line of cleavage to insure easy, rapid and safe dissection This technique was foreshadowed in a case on which the essavist operated, on Oct 30, 1894 Here he gained his first knowledge of the line of cleavage for intraligamentous cyst and reported it to the Columbus Academy of Medicine In 1896 Kelly announced the line of cleavage for intraligamentous uterine fibroid Hall (in 1897) was the first to combine all the essential factors of the ideal operation Hall's method, however, included hysterectomy The method of the essayist, without hysterectomy, is as follows, First tap the cyst and drain off its contents, then ligate the ovarian artery near the pelvic wall and place a clamp between the cyst wall and the uterus Select a point as low down on the anterior wall as practicable, and with a pair of forceps lift up the capsule and make a small opening Insinuate a finger and sweep it around, separating the cyst from its matrix at the base Now turn the finger upward and work in the direction of least resistance, slitting the capsule as you go This will indicate the line of cleavage and will generally run upward and outward diagonally across the face of the tumor Now introduce the hand and strip off the capsule from below upward, following the line of cleavage Enlarge the opening by making an incision parallel to the capsular margin, seize the cyst and roll it out of its bed, stripping it from the posterior capsular wall Trim and suture as in other cases

GENERAL CONSIDERATIONS ON SEPTIC INFECTION OF OVARIAN CYSTS

DR CHARLES GREENE CUMSTON of Boston read this paper, He said that inoculation experiments had shown that if the liquid contents of an ovarian cyst were uncontaminated by bacteria they would remain aseptic and would undergo no change But if, on the contrary, microbes attacked a cyst and entered it, its contents would serve as excellent culture media, and symptoms of infection would soon appear But the human organism would take on the offensive and would react against the bacteria which had infected the cyst, leucocytes came from the walls of the vessels and attacked the invading microbes, and thus we had the transformation into pus of the liquid contents There were two kinds of septic infection of ovarian cysts, namely, pathogenic infection and saprophytic infection Pathogenic and saprophytic organisms often entered ovarian cysts through puncture, incision and drainage As puncture was discarded in a great number of instances by the majority of the profession, the patient contained the agent of the septic process under consideration The germs did not come from without, but from the interior of the organism, and it may be called a true auto infection, which takes place in one of three ways 1, by means of the blood, in which case the infection was either direct, produced by phlebitis, which extended to the cyst, or it might be indirect, in which case the infective elements were carried in the general circulation into the tumor by means of its pedicle, 2, infection might take place by the lymphatics, in which case the lymphatic channels acted as the contaminating canals and allowed a direct introduction of the germs into the interior of the cyst up its hilum, 3, we had infection through adhesions, which were plentifully supplied in new formed vessels which were intimately connected with those in the walls of the cysts, and thus allowed an easy transportation of the bacteria

After giving at considerable length the symptoms of ovarian cysts and dwelling upon the diagnosis and differential diagnosis, the author dealt with their operative treatment Operation for the removal of ovarian cysts which were the seat of septic infection may be divided into four stages 1, incision of the abdomen, 2, the breaking up of the adhesions and ligature of blood vessels which they may contain, and then the pus may be removed by trocar and not with the knife, because if the cyst is incised pus will immediately flow out, and the wound will very likely become infected by the septic material, 3, extraction of the cyst through the wound—and in doing this the surgeon should be careful to avoid infecting the abdominal incision at the time he is drawing the pocket through, but this complication may be easily avoided if aseptic gauze sponges are tightly packed around and inside the line of incision Next comes the ligature of the pedicle and its section, after which it is dropped into the abdomen, 4, the fourth step of the operation consists in the cleansing of the peritoneum, which should be done with great care, especially when the operative field has run any chance of infection If this has occurred, free irrigation of the peritoneum is proper, but it should be done with care, and the liquid employed should be a warm, normal salt solution Care should be taken to limit the irrigation to the subumbilical portion of the peritoneal cavity, and a back flow of the liquid toward the diaphragm should be prevented by having the operating table perfectly flat and the thorax slightly raised

Dr HENRY HOWITT of Guelph, Ont, read a paper entitled

A SECOND CONTRIBUTION TO THE SURGICAL TREATMENT OF INTUSSUSCEPTION IN INFANTS, WITH CASES

In the paper the term "infant" was restricted to those under 1 year of age After briefly describing the different varieties of intussusception that occur at any period of life and also referring to particulars in regard to statistics, modes of growth, length of bowel involved and the severity of attack in the varieties, he states that in the infant we have only the acute forms with which to deal in practice, nay, possibly only the ileocolic, which all authorities agree to be the most acute and rapid variety of invagination It is, he states, the ileocecal form plus the valve distended and its lumen occluded by the swollen and edematous invaginated portion of ileum which, owing to the tight constriction at neck by valve, in a manner resembles a well hammered boiler rivet that no evenly distributed pressure from within can force out The author believes that many instances of the trouble occur in infants, leading invariably to death, without the true nature of the malady being recognized by the attendant, and that when the facts having reference to this variety of intussusception become generally known, fewer deaths will be recorded from certain bowel affections, and more lives be saved by surgical means He has seen seven cases, six of them almost within the past five years, or since his attention was drawn to the subject Six were in male children, all came from a district, the population of which is under 12,000 He has operated successfully on four, all of whom were under six months of age A fellow practitioner lost one owing to an accident, during operation In one case the friends refused operation and death resulted, and one died shortly after the onset, before anything could be done The symptoms of ileocolic intussusception were fully dwelt upon In regard to its diagnosis, the speaker emphasized the importance of the history of the onset, and stated that without it the attendant may be likened to a ship in a storm without helm or compass In fact, the nature of the onset might suffice to make a diagnosis The detection of a tumor in the course of the colon left no room for doubt The condition in this form of intussusception was such as to preclude the hope of recovery by any method short of operative No time should be lost in trying either bowel inflation or injection of fluids They could do no good His method of operating is as follows

He maintains the temperature of the child by suitable applications to extremities and body during operation. Rigid aseptic preparations and precautions should be carried out. A median, three inch incision, avoiding the high placed bladder, is made, the small intestines are eventrated as rapidly as possible, and protected with gauze, which is irrigated with water of suitable temperature. The evisceration allows the obstructed portion of intestine to be brought into view. When, as is generally the case, the invagination has reached the transverse colon, the surgeon can not bring it out of the wound till the part of the large bowel implicated is disinvaginated. This is accomplished by making pressure on the apex of the intussusceptum while the intussuscipiens is pulled in the opposite direction. It is done by grasping the colon close to the apex with hand and following it up the bowel step by step till the colon and cecum are free. The mass is now lifted out of the incision. Then comes the most difficult point, the reduction of the invaginated portion of ileum. The part is grasped in the hand and firmly pressed for a few minutes, the pressure is made with the thumbs on the apex, while the fingers surround and support the outer orifices of ileocecal valve. The method resembles that used in paraphimosis, only the large bowel covers the part from view. Before returning the intestines to the abdominal cavity the contents which have accumulated in the ileum above are forced through the affected part into the colon, this proves that the difficulty has been effectually overcome and ensures an early movement of the bowel. Drainage is not necessary. The omentum is spread over the intestines to prevent adhesion of the bowel to the line of incision. The dressing is covered with oiled silk, the edges of which are sealed with collodion to prevent urine reaching cut.

Dr. **Reed** said his experience was restricted to a single case of intussusception in infants. The child was operated *in extremis* and died within the first five hours following operation. With early interference the outcome might have been different.

Dr. **Price** said the cases reported were a beautiful demonstration of what can be accomplished by good judgment, great diagnostic skill and early surgical interference.

Dr. **W. E. B. Davis** thought it was unusual for one man to have as many cases of invagination in infants. He had only met with one case, and this occurred ten days ago, the child, a male, being 8 months old.

Dr. **Hall** recalled half a dozen cases of intestinal obstruction in infants' in sixteen years' general practice, that had died. He believes the invagination is overlooked in the majority of instances.

Dr. **John M. Duff** believes intussusception in infants occurs more frequently than is generally supposed. He had held post mortems on several cases where the diagnosis was doubtful, but intestinal obstruction was found. He had seen two cases within the past year, in one, operation was refused and the child died. At the autopsy intussusception was found. The other case was operated on after peritonitis had set in, followed by death.

Dr. **Cumston** had seen four cases of invagination in children.

First Day—Evening Session

Dr. **Joseph Price** of Philadelphia read a paper with the caption

NURSING IN ABDOMINAL SURGERY

He thought the time had passed when any question was raised by intelligent and experienced members of the profession as to the value of the trained nurse. Nurse training schools had become important institutions, not only to young women who, with a creditable ambition, entered them to fit themselves for the profession of nurse, but to the physician, for the physician, whether in general or special practice, knew the value of the trained nurse, understood the close and vital relation she held to his patient, how much her care and quick intelligence of the needs did to relieve his anxiety and promote the welfare of his patients. The training of these schools should be specially and simply directed to fit pupils for the duties of nurses. These duties in all their details, and all the steps in the training essential to discharge them faithfully and intelligently, should be definitely, orderly and clearly outlined by teachers of thorough experience. Those desiring to become nurses should commence their work early, while young, studious and ambitious, while their habits are not so fixed as to make a change difficult, if not impossible. Too much had always been expected of nurses in private nursing. Nursing through twenty four consecutive hours was too much to require of human endurance and resulted in neglect of the patient. Systematically trained special nurses were usually bright, cheerful, interested and spirited, were alive to the importance of their work, cared for and infused into their patient some of their own animation. The untrained nurse, on the other hand, was meddlesome and dangerous. Young, healthy, unmarried women were to be preferred, not widows or grass widows, great aunts or grandmothers.

Second Day—Morning Session

Dr. **W. J. Asdale** of Pittsburg read a paper in which he reported an interesting case of extrauterine pregnancy, with mature fetus, and exhibited specimen. The skeletal remains were borne seventeen years over the completion of gestation term, and the condition was eventually complicated by an ovarian cyst. No operation was performed. Patient died. At the autopsy a monocyst of the right ovary of large size was emptied and withdrawn. One of the long bones of a fetal skeleton was found in the pelvis, free, from high in the left hypochondrium underlying the left lower ribs and just beneath the diaphragm the remains were found, skeletal, of a fetal body, disarticulated and closely packed together. The bones were invested by the intestines, a portion of which was cut away in the removal. The fetal soft parts had, at the time of the autopsy, almost entirely disappeared. Records of successful operations undertaken for the removal of long retained fetal remains were so rare as yet to be exceptional, and how much more doubtful surely would be the result of operative interference in such a complicated case as this.

REMARKS ON PRIMITIVE AMENORRHEA, WITH REPORT OF A CASE AND PRESENTATION OF ACCOMPANYING PATHOLOGIC SPECIMEN

Dr. **Walter B. Chase** of Brooklyn read a paper on this subject, in which he said that the essential fact in the sexual life of woman was the predominating control of ovarian influence, and the central fact in the pathology of woman's sexual life was due in large degree to changes or perversion of function or structure of the ovary. While ovarian function was not the single influence which swayed woman's existence, the absence of it would dethrone her womanhood. The commonly accepted theory concerning the functional activity of woman's sexual life was that menstruation marked the commencement of ovulation, and that in its ordinary manifestations they were, in point of time, coincident. The experience of all observers doubtless furnished exceptions to the common law, but these exceptions served rather to confirm than abrogate it. Among these variations or absences of physiologic processes, amenorrhea in some of its forms was of common frequency. An intelligent and comprehensive distinction in amenorrhea embraced a difference between those cases which were congenital or acquired. In the former—*emansio mensium* or primitive amenorrhea—the causes were congenital, while in the latter—*suppressio mensium* or acquired amenorrhea—the causes were functional, or largely so. In the first class, menstruation has never been present, in the second class, the function once present is arrested. Primitive amenorrhea may result from congenital deficiency or imperfect development, as follows: absence or imperfect development of ovaries and uterus, degeneration of the ovaries, cystic or otherwise, the formation and development of benign or malignant tumors of the ovaries sufficient to preclude or abolish their function.

Report of Case.—Mrs. B., aged 24 years, a woman of refinement and fine physical development, had been married about two years, was sterile and had never menstruated. She gave an intelligent history of having had all of the symptoms which usually accompanied menstruation, since the age of puberty, except the appearance of the menstrual flow, commencing at about 18 years. The symptoms of discomfort developed with perfect regularity every twenty eight days, with a history of increasing pain and nervous excitability, until during the eighteen months previous to his having seen her the pain had become unbearable and nervous perturbation such that she and her friends feared insanity. The one subjective symptom which gave rise to her fears of mental disturbance was severe headache and pressure felt at the vertex, which was present for several days at each menstrual molimen. During a year or more she had become conscious of a gradual enlargement of the abdomen and could herself easily define an abdominal tumor. She entered the service of Dr. Chase at the Bushwick Hospital, and a careful study was made of her case by the consulting gynecologist and himself. The patient was desirous of an operation, which was performed. The first tumor removed was a dermoid and had no pedicle but was closely adherent to the uterus and the right broad ligament. The second tumor was a suppurating multilocular cyst of the left ovary. The report of the pathologist was: 1, that the dermoid had usurped the place and destroyed the function of the right ovary; 2, in one of the cyst walls of the multilocular ovarian [illegible] found a shrunken ovary the size of a large lima bean [illegible] this ovarian stroma was found a corpus luteum [illegible] the presence of this ovarian stroma was due the womanly development, with ovulation, and the futile effort of menstruation and its consequent suffering, 3, it demonstrates the possibility of ovulation without menstruation, 4, it leaves us in doubt whether the absence of the Fallopian tubes was primary or secondary to the grave disease of the ovaries, with the possibility that they were congenitally absent, 5, it presents the rare and exceptional condition of a perfectly developed woman who had an ovary and uterus, who ovulated, was sterile, and never menstruated, and yet was ruined in health by Nature's effort to establish an impossible normal function

The remainder of the session was devoted to the presentation and discussion of pathologic specimens Specimens were exhibited by Drs John B Deaver, X O Werder, Rufus B Hall, and Wm H Humiston

Second Day—Afternoon Session

The President's address was delivered by Dr **Charles A L Reed** of Cincinnati, on

THE EVOLUTION OF SPECIALISM

He said that modern specialism in medicine dated from the period when the French schools, in the early decade of this century, took up seriously the question of pathologic anatomy This was the physical basis upon which the work of division began The obstetric art was as old as the function of reproduction, although the latter ages had witnessed its present refinements It had been said that obstetrics married surgery, and that the fruit of the union was bright eyed gynecology The accouchement probably occurred at the time Recamier invented the speculum in 1801 While surgery had its first rational development in the United States in 1809, under the masterly hand of McDowell, everything from that day to this was essentially contemporaneous history, in which occurred conspicuously many of the proudest American names Specialism became a verity, in response to natural laws, which even today determined its destiny There was not a day but that the general medical profession became enriched in resource and potentiality by the accretions derived from specialism Each specialty, however assiduously cultivated, remained an integral part of the great general profession, the masters of which must ever stand as our ideals All specialists today were primarily the products of general medical culture

Third Day—Morning Session

Dr **D Tod Gilliam** of Columbus, Ohio, read a paper on the "Treatment of Granular Erosions of the Cervix," and reported three cases, which he had treated successfully by ligation of the cervical vessels

Dr **B Sherwood Dunn** of Boston, followed with a contribution of

THE RELATION OF NERVOUS AFFECTIONS TO DISEASES OF THE FEMALE PELVIC ORGANS

He limited his remarks to the great neuroses of neurasthenia and hysteria and insanity He was totally opposed to any operative procedure, except where pathologic conditions were demonstrable He had no confidence in operations upon healthy organs for the cure of any neurotic condition, and believed that such were now generally condemned by the profession He, however, looks upon the position taken by some neurologists, that there was no relation of cause and effect between the various neuroses and psychoses and disease of the female pelvic organs, and being as extreme and condemnatory as the advocacy of the removal of normal organs in the female pelvis for the cure of nervous diseases, by some ill advised persons calling themselves gynecologists In operating upon diseased conditions in the pelvis, the gynecologist did not expect to remove the symptoms of the neuroses, but only those symptoms properly belonging to the pelvic disease itself But strange and disappointing as it might seem to be to some of the critics, when those pathologic pelvic conditions were removed or corrected the nervous system, relieved from the source of unceasing irritation, gradually returned to its normal poise, and the patient was cured of her neuroses as well as her pelvic disease

Dr **Wm H Humiston** of Cleveland, Ohio, read a paper on the

GRAVER FORMS OF NERVOUS DISTURBANCES DUE TO ORGANIC CHANGES IN THE GENITAL ORGANS

In the last five years of his work the essayist had never operated upon a case in which the correlation between the diseased pelvic organs and the nervous symptoms was not clearly defined before an opinion from a neurologist relieved him of doubt of a nerve or brain lesion, with one exception He reported six cases in which great relief, in some cases cures, followed operative interference The first case was one of insanity, the second, melancholia, the third, neurasthenia, the fourth, insanity, the fifth, hystero epilepsy, and the sixth, hysteria The cases were reported with the hope that some effort would be made to secure for women confined in county and State institutions for the insane such surgical measures which would, in a large proportion of cases, be a curative means for their mental ailment, and which must, in a vastly greater proportion at least, improve their condition both mentally and physically

Dr **Rufus B Hall** of Cincinnati read a paper on

ALBUMINURIA COMPLICATING GYNECOLOGIC OPERATIONS

The Doctor referred, first, to the conditions predisposing to this complication He urged careful examination of the urine preceding operation, so as to determine, if possible, the presence of nephritis or other causes leading to suppression The most common cause is a preexisting nephritis, but unfortunately, in granular nephritis, a most careful examination of the urine may fail to show the presence of the disease One of these patients, after the operation, may have suppression followed by coma and death The Doctor said we might also have suppression following the operation in a patient with a fatty heart or with atheromatous arteries He considers it of the greatest importance to have the patient thoroughly prepared for operation If he finds the least indication of preexisting nephritis, he advises chloroform for the anesthetic, regardless of the age of the patient In his early operative work he used ether almost exclusively He cites 110 sections in which ether was given In thirty three cases there was a trace of albumin in the urine in the first twenty four hours In ten cases there was partial or complete suppression, and two died in coma During the time he used the ether, he operated on seven patients known to have nephritis They were given chloroform and are included in 500 sections where that drug was the anesthetic Eighty five of this number showed a trace of albumin in the urine in the first twenty four hours after operation Ten cases had suppression, and four died of uremic coma All patients who were known to have kidney disease were given chloroform There were 35, and the deaths in the chloroform list were from this number To avoid the dangers from the use of chloroform, the Doctor urged that its administration be entrusted only to one expert in its use The Doctor closed his paper with a resumé of the preliminary treatment he accords every patient about to be subjected to a section, of the manner in which he conducts his operations, and of the measures he employs if albuminuria occurs following the operation

Third Day—Afternoon Session

Dr **X O Werder** of Pittsburg gave the clinical observations of over one hundred abdominal sections for ovarian tumors

Dr **Frederick Blume** of Allegheny, Pa, reported a case of double uterus and vagina, with pregnancy in one horn, in which he excised the vaginal septum

The election of officers for the ensuing year resulted as follows President, Edward J Hill, Newark, N J, First vice-president, Edwin Ricketts Cincinnati, Ohio, Second vice president, A B Miller, Syracuse, N Y, Secretary, Wm Warren Potter, Buffalo, N Y, re elected, Treasurer, X O Werder, Pittsburgh, Pa, re elected Executive Council, A Vander Veer, L S McMurtry, W E B Davis, John M Duff, L H Dunning and Walter B Chase Indianapolis, Ind, was selected as the place for holding the next meeting, the time of which was left to the Executive Council

---

Gloucester County (N J) Medical Society

This society celebrated its eightieth anniversary at Wenonah, Sept 15, 1898

The President, Dr Geo C Laws of Paulsboro introduced the mayor of the Borough of Wenonah, who welcomed the assembly in a fitting speech, and at the request of the President, Dr Mordecai Price of Philadelphia responded

Dr **James Tyson** of Philadelphia then read an essay on

THE GENERAL PRACTITIONER

He said "A general practitioner is one who shrinks from no service which belongs to his art He is at once physician obstetrician, gynecologist, ophthalmologist—anything which has received a title in the differentiation of professional duties A hundred years ago, one man could do all that was expected of him Even then certain men were distinguished for operative skill, yet the entire field was considered within the province of one man Casting about for the field actually occupied by him we find he is one who practices, first of all, medicine in its broadest sense, including not only the diseases of children, but also skin diseases He practices midwifery In surgery, for the most part, he is often called upon in minor surgery and the simpler affections of the eye and ear The more complicated technique, which modern medicine has imposed upon the proper treatment of diseases of the nose and throat, demands vastly more time and trouble than the older treatment of these affections, yet the general practitioner can not escape it Orthopedics is practically excluded, while genito urinary affections necessarily fall within his province The term must include more in the country than in the city In the city he is limited in his work by the will of the patient In the country, in the truest sense, the physician is a general practitioner His qualifications should be correspondingly thorough He should have preliminary culture in the broadest sense much more than the specialist He should be college bred, able to read Latin, French and German Greek also would further fit him for his work He should be well drilled in physics, in chemistry, equally well in botany, mineralogy comparative anatomy and zoölogy—a biologist in the full sense of the term well read in standard literature, equipped with all that would make him ready and versatile, not only to enhance his own pleasure and enjoyment, but that he may appear the equal, if not superior, of those with whom he mingles—the intellectual equal of the most intellectual of his community, to whom all may go for information His professional education should be the best his money can obtain A cheap medical education is like a cheap garment It soon needs repairs, and is an ever growing disappointment to its possessor Hospital residence for a year at least is important He should be familiar with the microscope, ophthalmoscope, etc Thus equipped, his consulting room should be well appointed, his laboratory replete with instruments of research, etc, as well as necessary reagents for chemical work As indispensable as, more useful than a horse and buggy—in the days of the bicycle at least—is a neat, bright, quick witted, intelligent wife She is a treasure, a cheerful helpmate and a loving companion, keeps his books and talks over his cases with him She can learn to test urine use the microscope, and help more than a qualified assistant because she is actuated by love and a common interest Nothing is such a drawback as a slouchy, novel reading wife I have known more than one man's life blighted by such a companion To marry on nothing is ill advised, but one need not wait for ample means When he begins to see his way clear to reasonable success, he should marry a sensible well educated woman, a little younger than himself How now shall he attain success? By well directed, earnest effort Establish an office or consulting hour and maintain it The office hour is too much ignored by the country practioner It is soon found out and then his patients will be sure to expect him at that time Your general practitioner must be an early riser When his hour is ended, he must promptly start on his visits, not making his visits too long thus losing time and also the respect of his patients Still he need not indicate by his actions that he is in a hurry, this is harmful also With work well arranged, time will remain to spend in study of doubtful cases, reading, etc He must subscribe for one first class weekly journal, also a scientific one He must keep in touch with all that goes on in the world Abstracts and first class editorials he must have He should be a member of his local society He must win the regard of his fellows, ventilate his views only after he has acquired the faculty of speaking in a proper manner, and report interesting cases The State and National societies should claim his membership and attention He thus rubs off the cobwebs, renews or makes acquaintances, and while young may better offer his aid while an older practitioner goes to such meetings when at a distance Jealousies between doctors are unjustified, yet they are frequent especially in the country More than half are without foundation, the result of misunderstanding, misrepresentation hearsay, etc Acquaintance prevents this, as it makes a man know how well his brother is disposed toward him He should not be in a hurry to call in a consultant but should first call his neighbor and thus exhaust the local resources before he sends for a specialist from the city He may accomplish much for the patient and promote good feeling Next he has duties to the community He should guard it well lest any violations of hygienic laws cause disease, and should suggest measures for the relief of any such When this is done in a quiet unostentatious manner he will be listened to with respect and his advice will more likely be followed Cultivate social life this aids in many ways As to compensations money often is not the thing Well doing brings its own reward Many would give money who are not able, but give respect etc. Alluding to pictures of the general practitioner by the novelist the speaker concluded What a privilege to be a member of a profession in which such men abound What an honor to be one of those from whom such a type is drawn! Well may we glow with pride at the recognition it has received, and while taking new courage from the contemplation of such a life let us not fail also to allow our hearts to be softened by this example and bear with patience the many disappointments and petty annoyances that beset our daily path

The President then read an essay, having for its title

THE EFFECTS OF NITROGLYCERIN UPON THOSE WHO MANUFACTURE IT

In 1880 a large manufactory of nitroglycerin and its compounds was established upon the banks of the Delaware River near Gibbstown, three miles from Paulsboro, where he resided Many of the women and their families have become his patients and he has had ample opportunity to observe the effects of this material on the systems of those brought in contact with it He detailed the mode of manufacture and gave some account of its properties It was discovered in 1846 by Sobrers, later investigated by Railton and DeVrij It is a heavy, pale yellow fluid, inodorous, slightly soluble in water, soluble in alcohol It is formed by the action of concentrated nitric acid on glycerin, in the presence of strong sulphuric acid at a low temperature It is also called glonoin, trinitrin and propenyle nitrate It is the principal ingredient of all high explosives, such as dynamite, under its various names of Judson powder, explosive gelatin—the material used in submarine mines—and enters largely into the composition of smokeless powder Chemically it is an ether, being produced by the action of an acid (nitric) on an alcohol (glycerin) It is used medicinally in minute doses in large doses it is an acrid poison In the process of making, a large, tub like vessel is used, fitted with dashers, which are rotated horizontally by a compressed air engine The vessel is lined with lead and has an extra lining of a continuous coil of lead pipe, through which a stream of ice water is passed In the center is a large thermometer on which the workman keeps his eye while the charge is being run As the temperature rises he allows the flow of glycerin to increase as it lowers, he increases the flow of mixed acid Practice makes him expert and enables him to run a charge in about an hour This man's position is a trying one, as he stands with both hands on the levers and his eyes fixed on the thermometer, not for an instant dare he relax his attention The charge consists of 5500 lbs of mixed acid in the proportion of 170 lbs of sulphuric acid to 100 lbs of nitric and 14 per cent of 770 lbs of glycerin These are run into the tub through separate spigots After being thoroughly agitated together the charge is drawn off into a settling vat where the mixture separates by gravity into nitroglycerin and sulphuric acid The former is drawn off and thoroughly washed with water and the superfluous acid neutralized by an alkaline solution The sulphuric acid is run through pipes to another building where all the residual nitroglycerin is extracted by a freezing process The remaining acid is reconcentrated and again used The nitroglycerin is stored in tanks, from which it is weighed and distributed in lead lined copper buckets to the various sub departments In the manufacture of explosives it is mixed with sawdust nitrate of soda, nitrate of ammonia and nitrate of soda wood pulp, etc Explosive nitroglycerin is made by mixing 8 lbs of gun cotton, 10 lbs of oxid of zinc and 82 lbs of nitroglycerin boiled together at a temperature of 110 degrees This is fully as explosive as nitroglycerin, and safer and more convenient. Judson powder is made by heating a mixture of bituminous coal, sulphur and nitrate of soda and adding a proportion of nitroglycerin It is mostly hand labor, none relax the most intense vigilance As a consequence accidents are rare, when they occur there is no means of ascertaining the cause and there is little use for surgical assistance save in the case of those hurt by falling material The doctor has the gruesome task of identifying and collecting the remains In the apartments there is no noise all is absolute silence The machinery seems to work silently and even the men who drive the mules that haul the trucks do without the usual mule stimulus

The first condition to which my attention was called was known as the 'powder headache' All suffered from it who had anything to do with nitroglycerin in any way The head is generally sore this has to be experienced to be appreciated The workmen's wives who do the laundry work suffer severely every wash day Not only the underclothing worn by the men but any clothing even the bedclothes will cause this feeling In time they become inured but all [illegible] of the ironing Inhaling the steam from the hot clothes [illegible] very sick Rubbing a little dynamite on the [illegible] using a towel that a workman has used [illegible] lying on a lounge in one of their houses [illegible] a sleeping room auscultating [illegible] ache in one not accustomed to it [illegible] into the system by absorption or inhalation, acts on the vaso motor centers, causing dilatation of the left side of the heart and of the entire arterial system There is often a distinct reddening of the skin of the face and extremities, sometimes of a pinkish hue, changing to lividity, and blueness of the nails, lips, ears and nose, with conjunctival redness With this we have palpitation, thumping of the heart, pulse slightly quickened, soft and compressible, and an intense throbbing pain in the head, worse in the occipital region, and extending down the back of the neck At every pulsation the blood can be felt surging through the brain and in aggravated cases the movement of the blood can be felt in other parts of the body The affected person walks lightly on his toes, touching the heels to the ground sends an additional darting pain to the head Nausea and vomiting are often present, sometimes diarrhea, weakness, prostration and languor continuing over the next day Some are more susceptible, but all are affected to a degree My worst attack was caused by taking a nap on a lounge with my head on a pillow kindly loaned from upstairs by the nurse, on an occasion when I had to remain all night Occasionally the headache is absent, but nausea, vomiting or diarrhea are present One case had an eruption over the body like that from poison ivy After three or four attacks he was compelled to abandon the work In about a week's time the new men become accustomed to the poison and do not have the headache, or perhaps do not notice it, but nitroglycerin is rapidly eliminated and the relief is not permanent Two or more days' absence from work will cause a return when work is resumed Some have the headache every Monday morning Thirty men are engaged in filling cartridges and are called "powder punchers" The shells are paper cylinders dipped in paraffin, each holds from two ounces to a pound or more of dynamite They are filled by hand, with a funnel and rammer, the dynamite being taken up with a small wooden paddle The hands and arms are covered with the material, each man handles an average of 1000 pounds of dynamite, containing 50 per cent of nitroglycerin a day, making 2000 half pound cartridges After the headache and other acute symptoms disappear, another condition gradually develops This is dependent on a dilatation of the heart, particularly on the left side, and of the entire arterial system The pulse is soft, weak, obliterated by moderate pressure The first sound of the heart is accentuated, the apex beat exaggerated, murmurs resembling anemic are heard, but most frequently from aortic regurgitation, and occasionally from mitral insufficiency There is an engorgement of the left ventricle, the heart acts irregularly and palpitates easily The appetite is poor, especially for breakfast He rapidly loses weight, there are no dropsical symptoms, but a certain degree of mental dulness The punchers are especially dull and drowsy during work I call this condition "glonoinism"

The employes are all strong men who lead quiet, temperate lives, have the principal meal at the close of the day, use tobacco in moderation or not at all, rarely drink anything stronger than tea or coffee, alcohol in any form producing serious effects A simple glass of beer will cause headache, palpitation and reddening of the skin Cases have been known where men have become addicted to Gibbstown punch, composed of whiskey *ad libitum* and as much nitroglocerin as can be absorbed externally, the two mix in the system This compound is guaranteed to produce a more violent and serious form of intoxication than any other combination known to man Handling this large amount of nitroglycerin daily, the men's systems become impregnated, their wives, occupying the same sleeping apartment and doing the laundry work, become affected in a milder degree In these cases all symptoms are much milder, but similar to those mentioned before, the uterine functions are deranged, undue hemorrhage at the menstrual period is seen, they have premature births and fewer children Children born under these conditions are not as strong and vigorous as others of the community, cyanosis at birth is common, and they do not have the stamina to resist disease Diphtheria, not as a rule fatal with us, has had several victims in these families Other children's troubles are also especially severe and the fatality greater It is not safe for one of these men to carry his infant in his arms for any length of time, he is sure to have a sick baby Infants can not sleep in bed with their parents without dangerous results Early after the establishment of the factory the doctor was called to a child who had been taken in the father's arms to quiet it, both had fallen asleep, after two hours he awoke and found the child seriously ill, head back, moving from side to side, eyes partially closed—indeed in a collapse, death soon ensued Subsequent experience convinced him that the child was killed by contact with the father's body and clothing and by inhaling the breath All depressant remedies must be avoided The coal tar derivatives can not be used at all He found no record of phthisis among the men, but three of their wives have died of it, cases of pneumonia have died suddenly Bromids have no effect on the headache, and irritate the stomach Iodoform may be used when indicated, in capsules The treatment of glonoinism is palliative, and the work must be abandoned for a cure Strychnia gives the best results Dr Laws took the ground that it was probable that the use of smokeless powder so much by the Spaniards in the late war had caused their defeat so rapidly, owing to the glonoinism resulting to the men Had this been used by our men, it is possible that the majority of our men would have been very sick in a very short time, but possibly they could have become seasoned to it In the navy, with the movement of the vessels, the air might have blown off the results, but this point needs further investigation It is well known that sportsmen who use smokeless powder often suffer from headache, and this is an objection to the use of dynamite in mines, etc The combustion is never complete, and a large proportion of nitroglycerin is thus diffused in the atmosphere, or in certain cases the powder is found slowly burning near the gun He concluded by giving at some length the results of careful observation by instruments of precision

The Historical Address was delivered by Dr L M HALSEY, of Williamstown, and concluded the program A social hour was then spent, with a banquet, followed by toasts After an address of welcome, the AMERICAN MEDICAL ASSOCIATION was toasted and Dr Wm B Atkinson asked to respond The Doctor took the opportunity of showing the work done by the ASSOCIATION, its vast increase in power and membership, its relation to State and local medical societies, and urged upon all the importance to the profession of every respectable physician becoming a member, the benefit to each by the literature of the ASSOCIATION, the advantage of the membership to each, and finally the power it would give the ASSOCIATION in the counsels of the nation, if in place of 8000 members it had 50,000 or more, as it should have Then it could demand national legislation with the surety of obtaining it when backed by such a membership, extending to every town, city, etc, of the entire Union, and no longer would be seen the spectacle of the crying need of a National Board of Health with no attention paid to the demand on the part of Congress

SELECTIONS

Laugh and Get Well—*Scalpel* quotes the following story from "Bonaventure des Periere" "An ape is the hero of this discourse, *whose master fell sick of a fever, so grievously in fact* that the doctors had to be called in At first they clysterised him, and then they drew his blood, according to the mode of treatment at that time universally in vogue Next, for four consecutive days they drenched the poor man with drugs of various sorts, and finally he was ordered a mixture which the apothecary brought him with his own hands It was then early in the morning and the patient was asleep, so placing the bottle on a table and covering it carefully with a cloth, this black swan among practitioners, rather than interfere with nature's sweet restorer, incontinently departed After a little while the sick man awoke of his own accord and saw that his potion had arrived, but there was no one at hand to administer it to him, the inmates of his house having all gone out in order not to disturb his repose The door of the sick chamber happened to be ajar and presently in comes the ape to pay his respects to his master, but the first thing the inquisitive creature did was to mount on the table where the covered up medicine was standing Lifting a corner of the cloth he began to sniff at the open mouth of the flask, and, to judge by his expression, the odor was not much to his liking For all that he repeated the action several times, and at last ventured on a taste—*for his curiosity made it absolutely impossible for him* to refrain The compound had a bitter sweet flavor and master ape withdrew his muzzle very smartly, twisting his lips about in disgust and pulling the most comic grimaces it is possible to imagine Before long, however, the sweetness overcame him, and returning to the charge he took a second sip, then a third, and so on, until at last he finished the stuff.

The poor, long suffering patient's precious mixture was drained to the last drop! Now it happened that the individual in question, who was looking on all the time, was delighted beyond measure at the antics of the ape So much so, indeed, that he clean forgot all about his illness and burst out into such a hearty roar of laughter that he straightway recovered Owing to his access of joy, so sudden and so unexpected, his spirits revived, his blood grew thin and his humors returned into their proper channels, thus extinguishing the fever While he was revelling in his restored health the apothecary reappeared on the scene and inquired how he found himself and whether the last medicine had operated, but the ex patient was so full of merriment that he was unable to speak intelligibly He could do nothing but laugh, whereat the other waxed exceeding wroth, believing that he was the butt of the unseasonable mirth Then, with a great effort, the laugher contrived to exclaim 'Ask the ape what operation it has had' As may be supposed, this answer did not tend to smooth matters, and the incensed druggist was about to give vent to some furious rejoinder when lo! the ape himself afforded a practical solution to the imbroglio, while at the same time supplying proof as regards the potency of the mixture Comprehending at once that the animal must have acted as the sick man's *locum tenens*, and being happily gifted with a sense of humor, the worthy apothecary forthwith went off into a roar on his own account, and the situation, lately so strained, resolved itself into a friendly duel between the ex patient and his medical adviser as to which should laugh longest and loudest

Veratrum Viride in Puerperal Eclampsia—Dr John Gordon in the *Lancet* (January 15) reports that one hypodermic dose of five minims of the fluid extract of veratrum viride resulted in cessation of convulsions in the parturient woman, reduction of arterial tension and pulse rate, the laxation of the rigid os uteri After this labor progressed normally, consciousness gradually returned and after two days the patient was in good condition, no other treatment being used The case was interesting as having been treated solely by the action of veratrum viride, and therefore one is presumably free to deduce that the improvement which followed was due to the action of the drug The outstanding features in the action are the lowering of arterial tension, the slowing of the pulse rate and the absence of convulsive seizures after the dose of the drug was given Within fifteen minutes of administering the dose there was a perceptible change in the character of the pulse It had been firm, hard and bounding, but now became softer, was full and easily compressible The number of the beats was also reduced from 92 or 100 to 84, and there was slight inequality in the value of the beats Five minutes later the pulse rate was reduced to 72, in another five minutes the pulse had become 54, and fifteen minutes later still it had reached its minimum of 52 Afterward for two hours the pulse rate was taken at intervals of fifteen minutes and kept varying from 54 to 60 per minute When taken five hours later it was still 56 and five hours later again it was 60 The etiology of puerperal eclampsia is obscure The frequent albuminuria with which it occurs gave rise to the opinion that it was the result of uremia, although cases occur where there is no albumin present, and other patients with an abundance of albumin escape, it is thought that renal insufficiency is the most frequent if not invariable cause Traube and Rosenstein refer its causation to acute cerebral anemia resulting from changes in the blood incidental to pregnancy, the watery condition of the blood being associated with increased arterial tension Dr Angus Macdonald of Edinburgh found from postmortem examinations extensive anemia of the cerebro spinal centers with congestion of the meninges without edema He attributed the convulsive attacks to irritation of the vasomotor centers from an anemic condition of the blood produced by the retention in it of excrementitious matters that ought to have been thrown out by the kidneys Applying the recognized physiologic actions of veratrum viride we know that one of its alkaloids, jervin, is able to reduce the force of the heart beat by its direct influence on the cardiac muscle, and that it is capable also of producing a general vasomotor paralysis, that it likewise reduces the pulse rate by a direct action on muscle, while the other alkaloid, veratroidin, by stimulating the inhibitory nerves also reduces the pulse rate, and both alkaloids, namely, the jervin and the veratroidin, are, in addition, depressants to the motor centers in the spinal cord We have, therefore, in veratrum viride, an agent the physiologic properties of which meet the supposed pathologic conditions in puerperal eclampsia, namely, increased arterial tension and cerebrospinal excitement

Pasteurized Cream and "Viscogen"—A recent bulletin of the U S Agricultural Department treats of the sterilization of cream It shows that some of the advantages of this product are that it is more convenient to handle, there is less loss from spoiling, and it is free from disease germs The cream will keep for several days without souring An objection to pasteurized cream is its lack of consistency The cream does not appear to be so rich as normal cream, because it is thinner and less viscous, and does not whip so readily So strong has this objection become on the part of consumers that it has materially retarded the introduction of this method of supplying cream The Wisconsin Station has been studying the problem for some time, and has recently suggested a remedy It is found that the consistency of pasteurized cream may be completely restored by the addition of lime in solution On account of the slight solubility of lime the use of simple lime water is impracticable, as it dilutes the cream to an undesirable degree, although even lime water materially increases the consistency of pasteurized cream It is proposed to use lime dissolved in a solution of granulated sugar (sucrate of lime) Such a lime solution contains more than one hundred times as much lime as lime water Consequently it may be added to cream in sufficient quantity to produce the desired result without perceptibly changing the cream otherwise This solution of lime in sugar is called "Viscogen," on account of its viscous producing properties, and the treated products are called 'Visco cream," "Visco milk," etc "Viscogen" is not a commercial article, but may be easily prepared The method described by the Station for its preparation is as follows

Two and one half parts by weight of a good quality of cane sugar (granulated) are dissolved in five parts of water and one part of quicklime, gradually slaked in three parts of water This milk of lime should be poured through a wire strainer to remove coarse, unslaked particles and then added to the sugar solution The mixture should be agitated at frequent intervals, and after two or three hours allowed to settle until the clear supernatant fluid can be syphoned off Where large quantities are made, we have found it convenient to mix the ingredients in a revolving barrel churn The clear liquid (Viscogen) should be kept in well stoppered bottles which are filled full, for the reason that it absorbs carbonic acid from the air, thus reducing its strength and also because where air has access to the solution, it darkens in color after a time This latter chemic change, however, does not seem to impair its usefulness The quantity of lime recommended in the above formula is considerably more than will be dissolved by the sugar solution This excess is added because of the impurities contained in our Wisconsin lime, which is of dolomitic origin and hence contains nearly as much magnesia as lime As these impurities are practically insoluble in the sugar solution they have no effect in the prepared viscogen

PRACTICAL NOTES

On the Use of Thyroid—According to the *Medical News*, September 17, the Berlin professor, Dr Thierfelder has advanced the following opinion as to the modus operandi of thyroid therapeusis In the first place, the effects upon metabolism may be stated as follows 1 Upon the [illegible] metabolism and elimination, its influence is stated, by some, to remain normal; by others, including Chittenden, the elimination is stated to be slightly but uniformly increased, the diet remaining the same. Those observers who have found the daily elimination of nitrogen the same, or decreased, have possibly failed to take into account the injurious effect of large doses of thyroid upon the appetite and digestion, with consequent decrease in the amount of food (and nitrogen) ingested. The increase in the amount of nitrogen eliminated remains, however, always slight. 2. The effect upon general metabolism is shown by the decrease in weight which follows the prolonged administration of thyroid, especially if in excessive doses. As there is not a corresponding increase in the amount of nitrogen eliminated, this loss must come chiefly from the non-nitrogenous elements of the body, that is, fats or the carbohydrates. This is apparently proven in the following ways: *a*. There is a marked increase in the amount of the CO_2 eliminated by the body, showing increased oxidation of the carbonaceous materials of the body. *b*. The loss of weight is most pronounced in those suffering from obesity, leading to its use as an "anti-fat" remedy. *c*. In mild cases of diabetes mellitus the sugar may be made to diminish or disappear entirely under the use of thyroid. These effects may be explained by one or both of the following hypotheses: 1. It may exert a specific stimulating effect upon the areolar tissues of which adipose tissue forms only a modification, due to the deposition of fats. 2. It may increase oxidation by increasing the oxidizing power of the blood. Its demonstrable effects upon the blood are limited, usually showing a slight increase in the number of mononuclear leucocytes, other changes in the blood, found at times, being explicable by changes in the organism, the alteration in blood constitution being secondary, as for example, the increase in hemoglobin and red corpuscles after administration of thyroid in bleeding fibroids.

Compound Fracture of the Patella.—Mr. Battle, in the London *Lancet*, September 10, reports the case of a cabman, aged 53 years, who on April 22 was injured in the knees by the kick of his horse. On the right knee there was a transverse lacerated wound extending almost the whole width of the limb. Through this opening the interior of the knee joint could be seen, and it was at once evident that the right patella had been broken transversely into two large pieces, though several smaller fragments could be felt. The two large pieces formed about five-sixths of the patella. The wounds were temporarily dressed with an antiseptic application, and a back splint was applied to the right leg. On the evening of the day of admission, about five hours after the accident happened, the patient was anesthetized, and Mr. Battle proceeded to wire the bone. An incision three inches long was made directly upward from the middle of the horizontal wound on the right knee, the flaps were reflected on each side of this incision, and the knee joint was completely exposed. The joint cavity, the bony fragments and the surrounding parts were then thoroughly washed in a solution of perchlorid of mercury. Two or three small fragments required removal. The two larger pieces of bone were joined together with silver wire and the ends of the wire, after having been twisted, were hammered on to one of the fragments. The aponeurosis over the patella was united by silk sutures and the edges of the skin wound, having been carefully pared, were drawn together with interrupted sutures. A drainage tube was inserted through a separate incision in the outer side of the joint. A dressing of double cyanid gauze and absorbent wool was applied and the limb was enclosed in a plaster of Paris splint. The wound on the left knee was sutured and dressed in a similar manner. On April 22 the right knee was dressed and the drainage tube removed. On the 24th the temperature rose to 100, but fell to normal on the bowels being opened by an enema. On May 3 the skin stitches were removed and the plaster of Paris splint exchanged for a wooden back splint. On the 12th the patient was allowed to sit up and on the 19th the splint was removed, a small dressing only being applied. On the 24th he was discharged from the hospital; he had firm union of the patella and was able to walk. Further improvement has resulted.

Suppurative Splenitis from Tight Lacing.—Dr. B. M. Cromwell describes a case of suppurative splenitis caused by tight lacing and violent exercise, which was successfully treated by operation. The patient was a strong, healthy girl, 17 years of age, who in order to escape an impending shower ran for the greater part of a mile on a hot day. After running for some time she felt a pain in her left side, and reached home in a state of more or less collapse. The pain ceased before she reached home and did not return until the next day, after which it was continuous. Dr. Cromwell, on examining her two or three days afterward, found a deep sulcus about the margin of the ribs, and in answer to her inquiries the girl explained that while she was running her corset was loose enough but the band of her petticoat was too short and she had to pull it very tight to button it. Above and below the sulcus there was a marked tumefaction. Percussion revealed dullness over the whole left side, extending to near the brim of the pelvis and anteriorly to near the median line of the abdomen. The edge of the tumefied spleen could be plainly felt around the greater part of this dull space. The diagnosis was an enlarged and inflamed spleen, and as no improvement followed from iodin ointment and blistering, an incision was carried through the abdominal parietes into the substance of the spleen. At first there was a copious flow of bright arterial blood, then a small ribbon of pus was mixed with it, and as the pus increased in quantity the blood diminished until the escaping fluid consisted entirely of pus, which continued to be discharged for many days under the influence of poultices, and for several days after it ceased there was a discharge of serum. The total amount of blood, pus and serum was estimated at about 30 oz. The girl made a good recovery and is now in excellent health.—*Maryland Med. Journal*, Aug. 13.

Cocain in Ophthalmic Practice.—Dr. Theobald, in the *Johns Hopkins Hospital Bulletin*, writes a word of warning about the too free use of cocain in the treatment of diseases of the eye. It has come to be quite common for the general practitioner to use cocain in eye inflammations, the inducement being that it diminishes the pain temporarily and so causes a measure of relief. The conditions in which it is used are various. He says: "I have met with many instances in which it was prescribed in simple catarrhal conjunctivitis. There seems to be no indication for its employment under such circumstances, and it is capable of doing much more harm than good. Because of its pronounced disturbing effect upon the nutrition of the cornea, cocain is not a remedy to be used carelessly in eye diseases. It acts, as you know, through the sympathetic nerves or chiefly in that way, and, besides anesthetizing the eye, it dries the cornea to a remarkable degree. The cornea not only becomes dry, but the epithelium becomes loosened, so that it is easily rubbed off, sometimes by the friction of the lids, or from the slightest touch of the instruments used. Any agent that has so marked an effect as this upon the nourishment of the cornea certainly seems not to be a safe one to use, unless there is a clear indication for its employment. The field of usefulness for cocain, apart from its anesthetic action, is extremely limited. I scarcely think, indeed, there is any occasion to prescribe it as a remedy in eye diseases, though it may be used sometimes to increase the action of other drugs; for instance, atropia, or homatropia, will dilate the pupil more quickly and powerfully if combined with cocain. Even here I prefer to keep the solutions separate, and to instill the cocain first and then the atropia. It is also useful as preliminary to the application of astringents or caustics, like the sulphate of copper or nitrate of silver, as it greatly lessens the discomfort, but this is only another phase of its anesthetic action.

Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE, INCLUDING POSTAGE

Per Annum in Advance	$5 00
Foreign Postage	2 00
Single Copies	10 Cents

In requesting change of address give old as well as new location.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
No 61 Market Street (Occidental Bldgs) Chicago Illinois

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Henry P Newman, 100 Washington St Chicago Ill sending him a certificate or statement that the applicant is in good standing in his own Society signed by the President and Secretary of said Society *Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership*

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character intended for publication in the JOURNAL should be addressed to the *Editor* and all communications relative to the business of the JOURNAL proof sheets returned or in regard to subscriptions should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL

SATURDAY, OCTOBER 1, 1898

THE BACILLUS PYOCYANEUS IN HUMAN PATHOLOGY

In 1889 CHARRIN ("*La maladie pyocyanique,*") published a thorough research concerning the bacillus pyocyaneus Before that time practically nothing was known concerning this organism in connection with diseases of man or in animals, although its occurrence in green or blue pus had already been observed by GESSARD Experimenting upon rabbits, CHARRIN soon found that the bacillus gives rise to a disease of definite clinical entity, and to this he gave the name *maladie pyocyanique* Others have studied pyocyaneus infection in the dog, as well as other animals, but the rabbit is the most susceptible

Infections with the bacillus pyocyaneus in man bear a marked resemblance to the experimental forms, at the same time it may, like other pathogenic organisms, occur in a purely saprophytic condition in various parts of the human body Thus it has been found in the saliva, sputum and sweat, also in the stomach, and KOCH early observed it in tuberculous cavities and regarded it at that time as incapable of any pathogenic action

KOSSEL and others have pointed out its relation to certain cases of purulent inflammation of the middle ear in children ERNST[1] of Boston observed it in the pericardial exudate during life, and G BLUMER[2] found it in practically pure culture in a case of acute angina that clinically resembled diphtheria It has also been isolated in cases of urinary infection BARKER[3] and others have shown that it may produce interesting cutaneous lesions Meningitis, bronchopneumonia, diarrhea and dysentery have all been demonstrated to have been caused in a few instances by this organism And, finally, it has been shown by a number of observers that it may give rise to a general infection

In the *Philadelphia Medical Journal* of Sept 17, 1898 Dr LARTIGAU of Albany adds a report of three cases in which serious inflammatory conditions and general infection resulted from invasion of the bacillus pyocyaneus In the first case there was a general infection, which may have been primary in the cul-de sac of Douglas, thence extending to the general peritoneal cavity and into the system, but it would seem even more probable that the original infection came from the genital apparatus This case, and one of BARKER'S, demonstrate the occurrence of acute peritonitis due to the bacillus pyocyaneus In the second case the bacillus was isolated from hemorrhagic infarcts in the lungs and the right kidney, and from the exudate of a double serofibrinous pleurisy In the third case a general infection took place from an amputation stump of the leg, on account of long-continued necrosis of the tibia

Undoubtedly many cases of infection by the bacillus pyocyaneus escape recognition because the organism fails to produce its green pigment for days, or perhaps not until it has been passed through animals In a bacteriologic study of 200 cases of suppurating wounds, JADOWSKI[4] observed the organism only twice, in a systematic study of 800 consecutive autopsies made at the Johns Hopkins Hospital, BARKER encountered eleven cases of local pyocyanic infection, and the three cases observed by LARTIGAU were observed in the bacteriologic examination of 100 consecutive autopsies

The *maladie pyocyanique* in man resembles the other more familiar septicemias, the general symptoms are those of all infectious diseases The temperature usually remains high, irregular oscillations are not unusual The spleen is enlarged, and the urine ordinarily contains a small amount of albumin Specific pulmonary lesions may develop as bronchopneumonia and pleurisy Intestinal disturbances, are marked by diarrhea, the dejecta in some instances containing more or less green pus or, the pigment may become more marked after the stools have been exposed to the air Among other rather interesting symptoms are the cutaneous lesions in the form of bluish eruptions or petechiæ or more rarely, papular rashes These lesions are generally found on the trunk, limbs, and scrotum, and they may appear at different periods in the course of the disease From the fluid in the bullæ the bacillus pyocyaneus has been occasionally isolated

[4] Quoted by Lartigau

There is also a chronic form of the disease, which has been studied quite a little experimentally, and this is characterized by hemorrhages into the skin, paraplegia and monoplegia, neuritis, myelitis, contractures, and muscular atrophy, as well as vasomotor and sensory disturbances. This remarkable nervous form of pyocyanic infection has lately been observed in man. JADAKOWITSCH is quoted by LARTIGAU as having described an interesting case of this nervous type. The patient had a chronic eczema of the legs of ten years' standing, frequently complicated by periods of ulceration, the secretion being blue. At these times he would manifest peculiar nervous symptoms; thus, at the end of a period of suppuration, paresis and anesthesia of the whole right arm developed. After another siege of blue suppuration, weakness and wasting, with dyspnea and rapid pulse developed, recovery taking place four months later. After the third return of the blue suppuration there occurred diarrhea, sensory disturbances involving particularly the ano gluteal and scrotal regions, and in this stage the bacillus pyocyaneus was isolated from the urine.

Among the anatomic lesions of pyocyanic septicemia may be mentional focal necroses, hemorrhages, and parenchymatous degenerations. One especially noteworthy feature is the development of intestinal ulcers in systemic infection. These ulcers more frequently form in the small bowel. In some examples there is merely a superficial necrosis of the mucous membrane, sometimes diffuse, sometimes limited. As far as known, these ulcers, which rarely pass beyond the mucosa, have not caused perforation. There may also be an acute hemorrhage enteritis, with or without ulceration. The stomach is commonly the seat of such inflammation. There may be multiple minute hemorrhages into the serous membranes.

The diagnosis of local infections can be made only by means of bacteriologic examination. The diagnosis is frequently aided by the presence of green pus on the dressings. In cases of general septicemia it would be extremely hard to separate it from other forms of infection; the intestinal symptoms, if present, or the existence of blue or green pus in some local lesions, would be very suggestive. The WIDAL test might be of service in distinguishing typhoid fever from such cases. The demonstration of the bacillus pyocyaneus in the urine or in the stools might further the diagnosis. Experimentally the serum diagnosis in pyocyaneus infection has been demonstrated, and this might prove to be of considerable clinical utility.

POSTOPERATIVE PSYCHOSES

A subject that formed one of the chief themes for discussion at the late annual Congress of French Alienists and Neurologists and which was also prominently brought before the corresponding body in this country at its latest session may be fairly considered as one of the questions of the day of modern psychiatry. As presented, it is not altogether a simple one; it may be admitted that surgical interventions are sometimes followed by insanity and that there exists in such cases a relation of cause and effect, but it will still remain to be settled whether this is anything more than one of the accidents that may occasionally happen without any special significance, as well as—allowing this to be not established—whether there is any special type of mental disorder thus produced, and what particular class of operations are most likely to have such consequences. It is more particularly within late years that certain gynecologic operations have been largely credited with a special influence in producing mental disturbances, and this subject has been actively discussed, not only in the bodies mentioned, but also in the Paris Society of Surgery and elsewhere. It is not an unnatural presumption, when we consider the marked effects of early ablation of the testicles on the organization and the profound systemic disturbances that accompany the menopause, that the premature removal of, or interference with, the ovaries might be sometimes followed by serious mental disorder, and it is probable that this preconception has had its influence, not only in inciting observation in this direction, but perhaps also in affecting the estimation of the results of operations in so far as the special mental symptoms are concerned. A temporary or permanent mental disturbance following a gynecologic operation would be, it may be, more readily attributed to the interference with the ovary than to other causes—predisposition, general shock, the anesthetics used, etc.—that may have had the predominant part in its production. The theory of internal secretion which is just now prominently before the medical profession also affords suggestions in this connection that favor the notion that serious mental disturbances may follow ovarian operations. A priori, there would seem to be some reasonable grounds for the belief that there might be a special liability to postoperative psychoses from certain gynecologic operative procedures.

As regards surgical operations elsewhere than in the genital organs, the presumption is less evident, but postoperative mental disturbances may follow any kind of surgical interference and, according to one authority at least, they are apparently rather more frequent after operations on the eyes, than those of most other regions. From what we know of the mental effects of surgical operations in themselves, which have been made the subject of an interesting study by WHITE, a few years back, it would not seem improbable that an occasional attack of insanity should be one of their untoward results. Just how far, however, this is to be attributed to the operation itself and not to other accessory conditions is still, for most cases at least, an open question.

The report of M. RAYNEAU to the Association of

French Alienists and Neurologists and the discussion, in which such well-known alienists and surgeons as **Regis**, **Picque**, **Joffroy**, **Garnier** and others participated, are of especial interest as affording an index of what may be assumed to be the present state of opinion in that quarter on this special subject As a whole, they leave the question still in an unsettled condition and one that affords the chance of a rather wide choice of opinion without cutting loose from respectable authority According to M **Rayneau** there is no special type of postoperative insanity, and except in case of thyroidectomy or operations on the cranium, the chief part in the genesis of postoperative psychoses must be attributed to hereditary or acquired predisposition, where only a slight cause is necessary to upset the unstable brain As to any special liability from gynecologic procedures, he rejects it altogether M **Regis**, on the other hand, whose psychiatric experience is certainly wide enough to give weight to his opinion, held that there is a special type, that of mental confusion, that commonly appears in the insanity following operations, which itself may be due to various causes—shock, the anesthetics, septicemia and in the most typic cases, to auto-intoxication either already existing, or induced in persons of weak resistance by the shock of the operation itself Others in the discussion laid weight on the predisposition, and one with extensive army experience called attention to the rarity of this complication in military surgery, which he credited to the selection of recruits eliminating the predisposed The majority of French surgeons, it would appear, consider the operation itself and its locality as an unimportant factor in the production of these postoperative mental disturbances

The subject is a complex one, and it is evident that no one series of observations, however extensive, can have much value for the decision of the questions involved To get the complete facts as to the effects of operations on the mind the whole subsequent history of the patients must be followed up, and remote as well as immediate results be ascertained Especially is this true as regards the results of operations on organs like the ovaries and testicles and those on the brain itself Even the effects of extensive major amputations might well be studied for their remoter mental effects, the ablation of extensive portions of the body has its effects on the structure of the brain, and this may sometimes involve the mind Apparently little attention has been given to this possible later type of surgically caused mental derangement, but it is properly to be included in the postoperative psychoses

The mental disorders immediately following surgical operations may well be due in many instances to the effects of shock anesthetics, or any other of the multiple possible factors, and the question of predisposition is always to the fore In fact, the predisposed form so large a proportion of the population that it is almost remarkable that so serious a general provocation as is afforded by a surgical operation, with its adjuncts of toxic anesthetics, shock etc , is so rarely attended by immediate or secondary mental disorder

LEGITIMATE PRESCRIBING

Many editors have pointed out in the columns of medical journals the importance of accuracy in therapeutics, or in other words, the necessity of using those pharmaceutic or chemic substances which are placed in our hands in such a condition of purity or excellence that no doubt concerning their reliability can possibly arise It may not be out of place for us, at this time, to call attention to an even more pressing need on the practicing physician, and that is, the necessity of avoiding the use of compounds devised by persons ignorant of chemistry on the one hand, and of medicine on the other, who have sufficient pharmaceutic knowledge to be able to prepare for the market preparations pleasing in appearance, and who have sufficient capital and unlimited impudence to claim that most of the ills which afflict our patients can be relieved by the employment of their peculiar specialty There is not a physician in this broad land who does not receive several times a week circulars, advertising, not only legitimate pharmaceutic preparations, but various compounds of cheap and ordinary vegetable and mineral drugs to which have been given trademarks and registered names, and which, in consequence, cost the patient far more than a simple prescription containing the same ingredients Thus, it is well known to most of the profession that a very widely advertised drug, designed chiefly to relieve pain and reduce fever, contains as its most active ingredient, acetanilid, and we have before us, at this moment, a circular recommending a number of preparations, which supposedly contain quinin, to which are added other substances designed on the one hand to produce movements of the bowels, to act as a tonic, and to be a substitute for that most valuable and cheap alkaloid, quinin, itself Further than this every one of these circulars contains a number of letters from supposedly reputable practitioners, stating that they have used these products and obtained extraordinary results therefrom In some instances these results have not really been due to the use of the compounds named, but the patient has happened to improve at the time that they were administered, and, according to the argument of *post hoc propter hoc*, the new compound has received the credit, and the physician has congratulated himself upon the discovery of a new remedial agent, when in reality he should be condoling with himself that he has lacked ingenuity and common sense to such an extent as to have been unable to devise for himself a similar combination, and further, has been misled into awarding the credit for the recovery to a substance which does not deserve it

The very large number of compounds which are placed upon the market, which chemic analysis soon proves to be but mediocre preparations, is an illustration of the sad lack of medical education possessed by some practitioners It is humiliating to think how many of the profession are willing to take the "say so" of the commercial traveler, who often is neither a graduate of pharmacy nor medicine as to the therapeutic efficiency of some drug which he may be hawking about the country Is it surprising that the laity will patronize Indian herb doctors and traveling salesmen in highly decorated wagons, when physicians will use products compounded and marketed with no greater possibilities of reliability than those which we have named It is a characteristic of the Anglo Saxon race that they are independent in thought and action, but it would seem as if some members of the medical professional were willing to be led hither and thither by the specious arguments of persons who have no more claim to our confidence than that which they can win by a smooth tongue and flattery No physician should prescribe a remedy unless he has a clear idea of what he wishes to accomplish, and, therefore, it is necessary that he shall first make an accurate diagnosis, and second, that he should have a clear idea of the physiologic action of the remedy which he employs How is this possible when he is simply given the information that such and such a preparation is useful in such and such diseases, and has placed in his hands a combination unknown to chemistry, to the honest pharmacist and to the pharmacologist? Why should the physician prescribe such products any more than he would prescribe an herb handed to him by an old woman at the roadside, with the statement that she had found it useful in the treatment of certain ailments? She, at least, would have put it to the clinical test, which is something the average promoter of these combinations has never done Let us remember the old adage, "be sure you're right, then go ahead," and let us have enough respect for ourselves and our profession to give only those remedies which come to us through reputable and ethical channels

THE SUFFERING OF TROOPS ON TRANSPORTS

The daily press of this country has told us of the foul condition of the ships used in transporting troops from Santiago to Montauk Point, and of the bad water, bad food and bad treatment which our unfortunate soldiers received during the voyage which brought them from the field of victory, and of subsequent prostration by disease, to a convalescent camp in the United States No doubt there was much suffering on many of the troop ships The men were broken down by their exposures and by attacks of yellow fever, malarial diseases and dysentery Their transportation was decided upon to avoid the greater danger of a continued stay in the miasmatic locality which had sapped their strength Great danger attached to the process of removal Great care had to be exercised by medical officers at the point of embarkation to prevent the dissemination of yellow fever in these crowded vessels, and that no great disaster occurred on any of these ships reflects credit on the medical officers concerned It was to be expected that there would be much individual suffering on these ships, but certain official reports which we have seen indicate that there were few grounds for the extravagant headlines and ghastly exaggeration with which the newspapers greeted the arrival of every fresh transport Captain WALTER D MCCAW, Assistant-Surgeon U S Army, states that the Sixth and Thirteenth regiments U S Infantry embarked August 7, on the *Vigilancia* The troops were reduced to the last degree in health by malarial poisoning and repeated outbreaks of fever In fact, all were either sick and still suffering from fever or manifested the results of the previous attacks by extreme feebleness and profound cachexia The sanitary conditions on board were fairly good, the ventilation of the sleeping quarters of the men was satisfactory The vessel was not overcrowded, and plenty of deck room was available As the voyage was made in favorable weather the health of the command improved marvelously The travel ration could not be eaten by the majority of the men, but not soup was served, which proved of great value Sixty-seven men were on sick report on embarkation No death occurred during the voyage, and on arrival off Montauk Point, August 14, the sick list was reduced to fifty two, and these were mostly convalescent The gain in general health was most gratifying

Every statement made by the medical officer is sustained by General ADELBERT AMES, who was in command The vessel furnished ample and comfortable accommodations for officers and men, the command numbering 698 men The ship's officers and crew were attentive to all the wants of the command, providing every means possible to assist the troops in the preparation of their meals and making them comfortable in their quarters The water for drinking and bathing was good and plentiful The weather was exceptionally good during the entire voyage, and the health and spirits of the men improved each day

This relates to only one of many voyages made, but it suggests that if we had more of these official reports before us we would have to correct many of the impressions made upon our minds by the perusal of the press dispatches

THE INTERNATIONAL TEMPERANCE CONGRESS

Many persons have the impression that temperance work is confined to this country and England, while on the Continent, the art of moderate and temperate drinking has become so perfected that temperance work or societies are not needed It will be news to

CORRESPONDENCE

Concerning Criticism of the Medical Department

Parkersburg, W Va , Sept 20, 1898

To the Editor —Just now it seems to be the thing for every one to criticise everything pertaining to the conduct of the war, from the head of the War Department down all the ranks to the lowest officer in the field, all are under fire Meantime it is refreshing to read plain and courageous articles—statements of facts, similar to that of Drs Sutton, Senn and others who have served in the field and camp A new generation has come up ignorant of the unavoidable conditions that pertain to war, who have forgotten the hardships, cruelties and sufferings of 1861 1865, and who have expected an army to be created, drilled and made efficient from raw material in rank and file, without mistakes, that large camps be established, veritable cities in size, and where the unsanitary conditions arising from the congregation of many men would be avoided by strict sanitary precautions being carried out by men taken from civil life, who were ignorant of the science of military sanitation, indeed, men who were ignorant of the rights accorded by military regulation to secure proper food, medicines and camp hygiene In Dr Dabney's letter in the JOURNAL of the 17th, we have the criticism of a sanitarian who is painfully ignorant of the situation he presumes to criticise Let a city, if possible, spring up in the same time as one of these camps, fully supplied with sanitarians, and see whether it would be provided with a pure and adequate water supply! whether it would have an efficient administration for the disposal of garbage, of excreta, of sanitary cleanliness? Would these officers secure the co operation of the inhabitants to avoid the use of impure water, unhealthy food, maintenance of personal hygiene? Certainly not! Sometimes in mining towns we see similar conditions, and we see similar results It is not fair to compare the conditions in these camps with that in cities long established, with the organizations with years of experience behind them As to the moving of hospital trains and its attending dangers, we had somewhat similar conditions in 1861 1865, yet there was no widespread dissemination of typhoid fever, camp diarrhea or dysentery throughout the country As to typhoid fever, it prevails all over the country at this season In a majority of cases there is little disinfection of excreta secured From country, and towns on the banks of streams of all sizes, this excreta reaches the rivers from which towns and cities derive their water supply, and health authorities of all the States have not secured any abatement of the evil, by any means They have not yet, as far as I know, secured such detention of such patients while their excreta is subjected to such examination as he proposes for our army confrères to carry out Sanitary officers can direct that such and such procedures be carried out, just as the Surgeon General had done; and then fail to secure the performance Let us have a little common sense with our fault finding! A summer campaign in Cuba meant sickness and death, summer camps for northern troops in the southern States meant the same Our troops in these days have had easy times, save at Santiago, as compared with those in the days of 1861 1865, both blue and gray

In conclusion, Dr Dabney makes an invidious comparison between the medical men of the army and those of the Marine Hospital Service, and proves it by the case of the marines at Guantanamo, their freedom from disease as compared with the troops at Santiago, due, he thinks, to the superior skill of the Marine Hospital Service or surgeons It is the first time we ever have heard that the U S Marines are a part of the Marine Hospital Service and not attended by their own naval surgeons We think the conditions are not at all the same The medical men in the regiments were taken, in the case of volunteers, from civil life, appointed after examinations by boards chiefly appointed by the governors of the various States, and included many men who had served with the National Guard If ignorant, it is the fault of the system The volunteer surgeons appointed by the National Government included many who would adorn any position, either in military or civil service Of course there have been mistakes, bad appointments, and carelessness, but nothing like to the extent the critics allege May we profit by the experience and not be rushed into a war again before we are at least half way prepared for it Least of all let us of the medical profession throw stones at those of our brethren who are at the head of medical service in the army Respectfully,

W H Sharp, M D

Criticism of a Medical Directory

Mount Clemens, Mich , Sept 22, 1898

To the Editor —There has been a question coming up from time to time as to the reliability of the information published by R L Polk & Co , in their "Medical and Surgical Register of the United States " This question has been discussed *pro* and *con*, some claiming that it was reliable and others that it was not It has come to the notice of physicians generally that the names of men were inserted as practicing physicians, whose evidences of having graduated were rather shady, but not until the present year have I known of any instance where they have sought to compel physicians to buy their publication by giving them a bad standing before the public if they did not That seems to have been done in my case in the present edition without any other motive (further than that as treasurer of the Mount Clemens Sanitarium Co , they solicited an advertisement for two publications which they are getting out, namely "The Medical and Surgical Record," and the "State Gazeteer," which I did not think, from a business standpoint, would be a paying investment) In the two former editions, 1893 and 1896, the name and standing of the college at which I graduated were correctly given, but in the present edition, the statement concerning me is as follows "Alfred N Shotwell, R. ¶," followed by a mark which indicates, "claims to have graduated, but the records do not show that a diploma was granted to any one bearing this name " The fact of my graduation has never been questioned before, and I refer you as to the untruth of their statement, to the faculty of the Detroit College of Medicine, where I was graduated Feb 29, 1884, any member of it, or to any of the following societies The Michigan Medical, the Northwestern, the AMERICAN MEDICAL, and the Pan American It would seem that it is about time for physicians to make a stand in this matter, as farther down in the registration of this town (if you will follow it), appear the names of two masseurs among the names of physicians I know nothing whatever about the standing of these men, and it is foreign to the question, further than that they do not claim to be graduates of medicine, nor do they practice medicine in any shape or form Is this a register and directory of physicians, or is it a directory published simply for the dollars and cents that these people can get out of it? I shall be glad to take this up with you and furnish you any other data that I can, and will furnish certificates from the officers and faculty of the college at which I graduated, which will substantiate the statement that this publication is unworthy of the medical profession, and should be sat down upon by all reputable physicians as unreliable and unworthy of their confidence

If you will give this matter publicity through your journal in any way that you think proper, after a thorough investigation, I shall be very glad to have you do so

Very sincerely yours,

A N Shotwell, M D

A Grave Menace to the Public Health, A Correction

NEW YORK, Sept 24, 1898

To the Editor —In your issue of September 17, p 666, the statement is made in a letter signed by "T S Dabney, M D" "Eight hundred marines were camped for many weeks at Guantanamo and their health remained excellent, and why? Because the surgeons of the Marine Hospital Service not only understand preventive medicine, but they *practice it*"

I beg to correct the inference that the United States Marine Corps is under the medical supervision of the Marine Hospital Service The latter organization was established for the care of sick and disabled sailors of the merchant service, a "mercantile marine," as it is sometimes termed, thus, doubtless occasioning the misunderstanding

The United States Marine Corps is part of the United States Navy, and is cared for exclusively by the officers of the medical department of the United States Navy The writer would have been strictly within bounds if he had applied to them the statement that "every man in that service is qualified for the work he is assigned" Not only in our home ports, but on foreign stations their success in preventing inroads of communicable disease is noteworthy and commendable Furthermore, the officers, seamen and *marines* of the United States Navy are, first of all, cleanly in personal habits, second, obedient to orders and observant of sanitary requirements, and third, not given to whining (for *lactopeptin*, etc) and complaining because of the hardships incident to the service, three essential conditions in time of war Very respectfully,

ALBERT L GIHON,
Medical Director, U S Navy (retired)

Gonangiectomy

DUNNING, ILL, Sept 22, 1898

To the Editor —In one of my recent articles published in the JOURNAL I used the word gonangiectomy, meaning by it an excision of a portion of the vas deferens As it seems to be a new word, and since I have had a number of inquiries as to its root words or derivatives, I take this means of answering, and give first, the Greek, then the English equivalent, with diacritic markings for pronunciation, then the word as compounded, with its definition, "Lidell & Scott's Unabridged Greek English Dictionary" The translation may not be absolutely literal

γονή, gona semen
ἀγγεῖον, aggeion a vessel
ἐκτομή, ectoma excision, or cutting away

As compounded, gonangiectomy excision of a vessel carrying semen Very respectfully,

GEO W JOHNSON, M D

Secretary, Department of Health

FAIRFIELD, IND, Sept. 24, 1898

To the Editor —Some of the papers of our land have had much to say of sanitary conditions, and made attacks upon the medical department, the truthfulness of which will be brought out or refuted by investigation

Present reports from surgeons themselves prove the fact that they have done noble work, also that many embarrassing conditions arose not due to any lack of service upon their part, but because of limited authority, being handicapped by officers of other departments, and without medical knowledge

All general orders must come from the Secretary of War and in such trying times it seems quite enough for him to give attention to other duties In truth, this department should be directed by the Secretary of the Board of who should a member of the cabinet and a physic his duty to look after sanitary conditions give general orders to surgeons, and see that is equipped for efficient work, and care for the noble men, "our soldiers"

Not only is there a demand for this additional cabinet member during war, but he would fill a long felt want in times of peace, and prove a valuable addition to the president's family

Yours respectfully THOMAS L COOKSAY, M D

Instruments for Fen Cho Fu Hospital

SIOUX CITY, IOWA, Sept 19, 1898

To the Editor —Thanks are due to the JOURNAL as well as Dr Webster of Chicago and Dr Green of Dubuque, Iowa, for so soon as their gift of surgical instruments arrives at Fen Cho Fu Hospital, Dr Atwood will no longer have to amputate limbs with a saw made of a piece of band iron The appeal through the JOURNAL and the response by the doctors sends the instruments Very respectfully,

MARY A ATWOOD

PUBLIC HEALTH

Yellow Fever in the South —In special dispatches in the *Chicago Daily Tribune*, September 26, four undoubted cases of yellow fever to date, with two deaths and one recovery, were reported from Jackson, Miss seven cases and one death from New Orleans, and ten cases from Oxford, Miss There are no cases in Alabama and the quarantine is entirely in the hands of the State authorities Refugees fleeing from Jackson are not permitted to stop within the State of Alabama

Health in Michigan —Reports to the State Board of Health for August give diarrhea, rheumatism, neuralgia, bronchitis, and cholera morbus as the five most prevalent diseases for the month Compared with the preceding month, dysentery, cholera morbus, cholera infantum, typhoid fever, diarrhea and inflammation of kidney increased in area of prevalence

Health in Chicago —The report of the Department of Health for August gives the total number of deaths during the month as 1977, a rate of 1 22 per 1000 as compared with 1 21 per 1000 for the corresponding month in 1897, and 1 40 for August 1896 The principal causes of these deaths were Diarrheal diseases, 261, other acute intestinal diseases, 231, diseases of the nervous system, 234, consumption, 184, heart diseases, 84, pneumonia, 78, cancer, 63, typhoid fever, 45, diphtheria and membranous croup, 41, bronchitis, 37 Those under one year of age numbered 595, those between 1 and 5 years, 251

A Warning Against Antifebrin —An inquest was recently held in London on the body of a young man who died from taking powders containing an indeterminate quantity of antifebrin The powders were taken for the relief of headache Antifebrin, like most analin derivatives, is a drug which should be employed with especial caution It is official under the name of acetanilid, and its potency is sufficiently indicated by the fact that the maximum dose assigned to it is only three grains There have been many cases of poisoning from the injudicious administration of this remedy, the symptoms produced by it being of the anilin type The patient usually complains of giddiness, noises in the ears, throbbing in the temples and a dull, heavy pain in the head The face becomes livid, the lips are blue, and the pupils are contracted This is followed by symptoms of collapse the face and extremities are cyanosed the skin is covered with cold, clammy perspiration, the pulse is feeble and respiration becc and frequent fic antidote, and tration of chasers being chiefly young women of a seamstress class Many people acquire an unfortunate habit of dosing themselves with remedies of unknown composition, and this death under such sad circumstances may be taken as an indication that the custom is not one which can be indulged in with safety —*Brit Med Jour*

Requisites for a Tuberculosis Retreat —The requisites for a sanitarium are as follows 1, a well arranged building with a southern aspect, 2, a dry, pure, well drained subsoil, 3, a pure atmosphere with abundance of sunlight, 4, a garden well protected from the wind, 5, sheltered verandas, galleries or arbors facing the sun, 6, constant supervision by specially trained medical men, and 7, an adequate nursing staff High altitude is an advantage, but is not essential As pointed out by Dr Rufenacht Walters, all these conditions may be found on British soil, and there is no necessity for consumptive patients who can not conveniently leave home to go abroad in search of health Three years' experience at Cromer has convinced Dr Burton Fanning of the practicability and utility of the open air treatment in England He shows how the disadvantages arising from the capriciousness of our climate may to a great extent be obviated by a more elaborate provision of shelters and coverings than is required under brighter skies There is some reason to believe that the climatic influences of foreign stations, though in themselves more favorable, may have disadvantages which make them ultimately less beneficial in the case of British patients than treatment in home sanatoria Many leading German authorities hold that a cure effected in a more genial climate is less assured than one which has been obtained in the native country of the sufferer —Malcolm Morris, in the *Practitioner*

Practical Sanitation —The Health Commissioner of Chicago has sent the following circular letter to some 3500 or 4500 individual producers of milk for the Chicago market, throughout an area extending more than 120 miles from the city—the farthest point being Logansport, Ind , 123 miles distant

DEPARTMENT OF HEALTH CITY OF CHICAGO

ARTHUR R REYNOLDS, M D , COMMISSIONER OF HEALTH
SEPTEMBER, 1898

To the Producers, Handlers and Shippers of Milk for Chicago

The return to their homes of so many of our soldiers sick with or convalescent from typhoid fever has a special interest for milk producers, as well as for health authorities, at the present time Hundreds, and probably thousands, of these sufferers are scattered throughout the area in which milk is produced and shipped to the Chicago market—on farms and in villages, small towns and other places, which drain directly into the streams that furnish the water supplies of dairies and milch cows

It is highly probable that many of these streams will be or already are polluted by the typhoid fever poison, and it is positively known that the disease may be conveyed in milk received and carried in vessels washed in such polluted water One observer, the eminent sanitarian, Ernest Hart, has investigated 97 outbreaks of typhoid conveyed by milk, which caused upward of 5700 cases and 656 deaths

The quality of the milk supply is of vital importance to Chicago It has greatly improved during the last few years, and the deaths of infants and young children, for whom milk is the staple article of diet, have diminished in direct proportion to this improvement A recent report of the Department shows a saving of 1530 children's lives last year compared with the average number prior to 1894, when the supervision of the milk supply was fully undertaken by the Department of Health

In this supervision it has been the aim of the Commissioner to secure the co operation of milk producers by showing that their interests are best promoted by improving the quality of their supplies Such improvement and its effects have been repeatedly shown to the Chicago public by diagrams, tables and other matter furnished to the newspapers and published in them and in the Department reports One result of this publicity is seen in the great increase in the milk shipments to the city In 1896 the average daily receipts of milk by railroad amounted to 13,275 cans Last year, 16,450 cans were received daily, or 48,034,000 gallons during the year This is an increase of 9,271,000 gallons more in 1897 than in the previous year, or nearly 24 per cent There has, of course, been no such increase in the population of the city, and the conclusion is, therefore, irresistible that mothers having been taught that the milk supply is of better quality, are feeding their children more generally and more liberally with this best of all food for the young

This consideration alone, would warrant the Commissioner in directing the attention of milk producers to the threatened danger of typhoid, and in asking their co operation and assistance in preventing or restricting the evil as much as possible

No producer can afford to have his milk infected with the typhoid poison The methods of the Department are such as to make it certain that any outbreak of this disease in Chicago, caused by infected milk, will be located in the dairy from which the milk was shipped, and it would then, not only be the bounden duty of the Commissioner to prohibit the receipt and sale of such milk in this city, but the publicity which would surely be given to such prohibition would ruin the business reputation of the unfortunate producer

All concerned in the production, handling and shipment of milk for the Chicago supply are, therefore, earnestly requested for their own interests, as well as for the interests of health and life in Chicago

First, to keep posted as to typhoid fever in the vicinity of their places of business—especially with relation to the sources of their water supplies

Second, to notify the Chicago Health Department immediately on learning of any case of the fever in their respective neighborhoods

On receipt of such information an inspector will be sent direct to the locality to ascertain the exact condition of affairs and the extent of the danger of milk infection, and to advise and assist in proper precautions

No charge will be made for such inspection and assistance, but all the resources of the Department, its laboratory and its skilled experts, are freely offered to those to whom this circular letter is addressed ARTHUR R REYNOLDS, M D ,
Commissioner of Health

This is practical sanitation on a broad scale and the example is one which might very properly and profitably be followed by State boards of health and other sanitary authorities in warning against the probable spread of typhoid fever from the cause indicated and in instructing in known measures of precaution

Sanitary Results Afforded by the Filtration Plant of Lawrence, Mass —According to the *Public Health Journal*, the effect of the changes made in the water supply of Lawrence, in 1893, was very promptly felt in an improved state of the health of the town The work was completed on September 20, of the year named, at a cost of $65,000, and from that date up to the present time it has been in continuous use, and not once has the unfiltered water entered the reservoir or the service pipes of the city water supply It was the intention of the designer that the filter should be operated as an intermittent filter, that is, that the surface should be uncovered or free from water every day for a period of two or three hours, it being his opinion that better results would be obtained by this method of operation than could be obtained by operating it as a continuous filter, that is, one whose surface is never uncovered, except at times of scraping The intermittent method of operating is followed during the summer, but in the winter the surface of the filter is seldom uncovered except at times of scraping During the year 1894, the first entire year of operation, the bacterial efficiency of the filter was 98 46 per cent during 1895 it was 98 22 per cent , and during 1896, it was 99 32 per cent The efficiency of the filter in removing bacteria has always been greater in summer than in winter, the reason of this being that, contrary to the advice of the designer, the filter remains uncovered, and thus unprotected from the severe cold of the winter of the climate In the January following the starting of the filter, the number of typhoid fever cases was nine, or one eighth as many as during the previous January. This fact is more striking when we note that in Lowell during this month there were ninety nine cases, or three times as many as during the previous January In January, 1895, there were ten cases in Lawrence, in January, 1896, six cases, and in January, 1897, two cases A more satisfactory demonstration of the effect of the filter upon the health of the people of Lawrence can be made, however, by stating that in 1887 the deaths from typhoid fever were 11 75 per 10,000 of the population, in 1888, 12, in 1889, 13 75, in 1890, 13 33, in 1891, 11 20, and in 1892, 11 11 per 10,000 During 1894 the filter was built, and hence during a portion of the year filtered water was being used In 1894, however, filtered water was in use during the entire year, and the death rate from typhoid fever was 5 per 10,000, during 1895 it was 3 07, during 1896, 1 86, aud during 1897 1 62 per 10,000 That is to say, the average death rate for the six years previous to the construction of the filter was 12 36 per 10,000, while during the three years and ten months following its construction, it has been 2 95 per 10,000 of population, a reduction of 76 per cent It can be said also, that a number of the deaths reported each year are operatives in the large mills who, in spite of the warning notices, drink the unfiltered and polluted canal water which is piped into these mills In fact, it can be said that Lawrence now has one of the lowest death rates from typhoid fever of any city in the State, and has its greatest number of cases during August, September, and October The cases occurring in these months can not in any way be connected with the filtered water supply Besides giving a water free from disease germs, the filter is giving a cleaner water, one more attractive and palatable, and containing but 50 per cent of the organic matter of the river water

The Use and Abuse of Food Preservatives —Considerable contention has waged round the legality or desirability of employing preservatives in perishable articles of food and the subject naturally comes to the front during hot weather such as that which we have been experiencing for the past three weeks There is little doubt that some means of preserving food are absolutely necessary when the prevailing conditions are such as to turn food in a few hours Otherwise milk, cream, meat, etc, become unfit for consumption, unpalatable and evil tasting To keep the articles somewhat near freezing point is obviously impracticable on any large scale, while sterilization is similarly beyond application This reduces our resources to the simplest of all expedients, the addition of an antiseptic in such quantity as to preserve, at any rate for a time, the articles from objectionable change and yet in minimum quantity so as not to constitute a possible harmful amount We think the use in limited quantities of such mild antiseptics as borax to be justified at a time like the present when otherwise a considerable amount of valuable food substances would be wasted and lost But, as we have urged before, the fact of an article being thus preserved against change should be always notified to the consumer, and we would have limits imposed by the State as to the amount of the preservative to be used, moreover, the nature of the preservative should also be declared In other words, we would establish a system, recognized by the State, by which under certain circumstances the employment of preservatives with restrictions as to their nature and amount could be legalized There has recently been made an important contribution on the subject by Professor Chittenden of Yale University As the result of a series of very interesting experiments this physiologist reports that the results would appear to warrant the statement that in particular boric acid and borax when present in moderate quantities can have little or no deleterious effect upon the more important chemic processes of digestion On the contrary it would appear that the presence of these agents may, in some cases at least, even accelerate the normal digestive processes of the alimentary tract In regard to the effects of borax and boric acid on nutrition the same observer concludes that when borax is given in sufficient quantity to produce any effect its action is similar to that of common salt, i e, it tends to increase proteid decomposition Both borax and boric acid, he states, are without influence upon the putrefactive processes of the intestine apparently because of their rapid absorption from the intestinal tract and quick elimination through the urine —*Lancet August 27*

BOOK NOTICES

Twentieth Century Practice An International Encyclopedia of Modern Medical Science By leading authorities of Europe and America Edited by THOMAS L STEDMAN, M D, New York City In Twenty Volumes Volume xv, "Infectious Diseases" New York William Wood and Company, 1898

This volume continues the articles on infectious diseases The contributors are Prof Dittmar Finkler, M D, of Bonn, who has contributed nearly one half of the volume, 249 pages on influenza, Eduardo Licéaga, on typhus fever, 72 pages, Dr S Kissato Katsagawa, on Asiatic plague, Dr Frank S Billings, on glanders and anthrax, Ismar Boas, on foot and mouth disease, M L Ponfick, on actinomycosis, N J Keirle, on rabies, J McFadden Gaston and J McFadden Gaston, Jr, on pyemia and septicemia These authorities have produced a series of essays truly representative of medicine at the close of the nineteenth century on the subjects treated, and it would be difficult to find authors who could write on the respective topics assigned them with better knowledge of the subject in hand The history of influenza by Finkler is alone worth the price of the volume He has made free use of that storehouse of epidemiology, Thomson's Annals, which very fairly covers the period from 1510 to 1837, especially in Great Britain, but we have here by Finkler an account of the preceding epidemics, the disease commencing, on the authority of Hirsh, in 1173 He has also brought his history down to the year 1894 The studies of Pfeiffer and Beck, Huber, Voget, Van Selow, Danco, Babes, Nastinkov and Max Richter are given in full

Medical Diseases of Infancy and Childhood By DAWSON WILLIAMS, M D, Physician to the East London Hospital for Children In one 12mo volume of 629 pages with 18 illustrations Cloth, $2 50, net Lea Brothers & Co, publishers, Philadelphia and New York

The author has treated the subject from the broad standpoint of general medicine, but describes fully the special modifications and complications incident to infancy and childhood The volume contains 47 chapters, viz Introductory, clinical examination, diseases incidental to birth, food, acute specific infectious diseases (4 chapters), malarial fever, tuberculosis (4 chapters), syphilis, rheumatic fever, chronic rheumatic affections, infective arthritis, chorea, rickets, scurvy, anemia, leukemia, hemophilia, diseases of the thyroid and thymus glands, diseases of the heart, diseases of the mouth, diseases of the upper respiratory passages acute bronchitis bronchial pneumonia and pneumonia, pleurisy, chronic affections of the bronchial tubes, peritonitis, diseases of the liver, acute disorders of the gastro intestinal system, intestinal obstruction, intestinal parasites, hydatid diseases of the genito urinary system, diseases of the nervous system (8 chapters), diseases of the skin (2 chapters)

This is a carefully considered work, and will be extremely useful to students and others in keeping abreast of the literature of the time on this subject

I Raggi di Roentgen e loro pratiche Applicazioni Di ITALO TONTI Milano Manueli Hoepli 1898

II La Cure Razionale dei Tisici e i Sanatorii Del DOTTOR ARNOLDO ZUBIANI Milano Manueli Hopeli 1898

These two little volumes from the Milan publishing house of Ulric Hoepli are in evidence of the demand of the Italian medical profession to be kept in touch with the latest results of scientific investigation The first is a convenient handy manual of actinoscopy that appears to be though brief tolerably full and up to date It is profusely illustrated with skiagraphs that are reproduced in half tone and which are very clear and intelligible

The second volume is a discussion of the treatment of tuberculosis with special reference to the care in sanitariums and by the open air treatment rather discarding the serum therapy methods that have been and are still somewhat in vogue T author makes a strong plea for the establishment of such sanitaria for the benefit of the poor

Both works appear to be useful contributions to these special subjects

Diseases of Women, A Manual of Gynecylogy Designed expecially for the use of Students and General Practitioners By FRANCIS H DAVENPORT, M D, Assistant Professor of Gynecology in the Medical Department of Harvard University, Boston New (3d) revised and enlarged edition In one handsome 12mo volume of 387 pages, with 155 illustrations Cloth, $1 75 net Lea Brothers & Co, Philadelphia and New York

This manual is not intended for specialists, yet specialists will find it interesting All the important topics of gynecology are here discussed, and discussed intelligently It comprises 20 chapters, viz, Introductory, anatomy, methods of examination, diseases of the vulva, diseases of the vagina, dislocations and lacerations of the vagina, displacements of the uterus, anteflexion of the uterus, inversion, inflammatory conditions, laceration, fibral myomata of the uterus, malignant diseases of the uterus, disorders of menstruation, disorders of the ovaries, tumors of the ovaries, diseases of the fallopian tubes, pelvic peritonitis, pelvic cellulitis, pelvic hematocele, diseases of the urinary organs

As a recitation book for students, this work is extremely useful, and the practitioner will not go far wrong if he adds it to his library and is guided by it

A Text Book of Practical Therapeutics, With especial Reference to the Application of Remedial Measures to Disease and their Employment upon a Rational Basis By HOBART AMORY HARE, M D, Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia With special chapters by Drs G E DE SCHWEINITZ, EDWARD MARTIN and BARTON C HIRST New (seventh) edition In one octavo volume of 770 pages, illustrated Cloth, $3 75, leather, $4 50, net Lea Brothers & Co, Philadelphia and New York

This well known text book now appears annually, each year fresher and with the latest fruits of the medical literature of the period, succinctly classified and inserted in the revision Few men have succeeded better than Dr Hare in, first, ascertaining what is wanted by his colleagues, and, second, in supplying it with intelligence The system of indexing and cross references adopted makes the work very convenient The work is masterly and authoritative

The Essentials of Histology By EDWARD A SCHAFER, F R S, Professor of Physiology in University College, London New (5th) edition Revised and enlarged Octavo, 450 pages, with illustrations Cloth, $2 00 net Lea Brothers & Co, publishers, Philadelphia and New York

This book, as the former one, is divided into 46 lessons, and is intended as a recitation and practice book in the laboratory The present edition contains 50 pages more than the former one, and is enriched by 67 additional engravings Full instructions for the microscopic examination of tissues is given The work is destined to maintain its popularity

Elements of Histology By E KLEIN, M D, F R S, Lecturer on General Anatomy and Physiology in the Medical School of St Bartholomew's Hospital, London, and J S EDKINS, M A, M B, Joint Lecturer on and Demonstrator of Physiology in the Medical School of St Bartholomew's Hospital, London In one 12mo volume of 506 pages, with 296 illustrations Cloth, $2 00, net Lea Brothers & Co, Philadelphia and New York

This is a masterly guide to the science of histology, without which neither anatomy nor physiology can be properly comprehended It is, as the preceding work, a treatise on microscopical technique, but, as its name indicates, is strictly confined to the subject of histology The present issue is a thorough revision in every respect, and contains much additional matter Although the work is very concise, compressed in 488 pages, it contains all the essentials upon the subject of normal histology We commend the work to our readers, feeling sure they will not be disappointed in it

A Clinical Manual of Skin Diseases, with Especial Reference to Diagnosis and Treatment For the use of students and general practitioners By W A HARDAWAY, A M, M D Second edition, revised and enlarged, with 42 engravings and two plates, pp 557 Philadelphia and New York Lea Bros & Co 1898

This book is divided into two parts, of which Part I contains introductory observations on symptomatology, causes of skin diseases, diagnosis, local distribution of skin diseases, treatment and classification, Part II, diseases of the skin proper, inflammations, hemorrhages, hypertrophies, atrophies, new growths, neurosis, diseases of the appendages of the skin, sweat glands, sebaceous glands, hair follicles, nails, parasitic diseases and animal parasitic infections The work is well illustrated, and carefully written As in the past, it will continue to be a favorite We sincerely hope, however, that in the next edition the decimal system of dosage will be used in the prescriptions

Examination of Sources of Public Water Supplies Cloth, 258 pp Maps Cleveland J B Savage Press, 1898

This volume is a "Preliminary Report of an Investigation of Rivers and Deep Ground Waters of Ohio as Sources of Public Water supplies," made by the Ohio State Board of Health during 1897-98 It contains, "Report on Stream Pollution," by Allen Hazel, "Report on Chemic Examination of Waters of the Scioto, Olentangy and Mahoning Rivers," by N W Lord, "Report on Bacteriologic Examination of Waters of the Scioto," etc, by A M Bleile, "Report on Stream Gaugings and Sources of Pollution," by C N Brown, and a "Report on Rock Waters and Flowing Wells of Ohio," by Edward Orton

A Treatise on the Science and Practice of Midwifery By W S PLAYFAIR, M D, LL D, F R C P, Emeritus Professor of Obstetric Medicine in King's College, London Examiner in Midwifery to the Universities of Cambridge and London Seventh American from the Ninth English Edition In one very handsome octavo volume of 700 pages, with 207 engravings and 7 full page plates Cloth, $3 75 net, leather, $4 75 net Philadelphia and New York Lea Brothers & Co, publishers

This edition of Playfair gives evidences of complete revision, and it will doubtless remain, as heretofore, a favorite text book with students and practitioners The chapter on conception and generation has been re written A number of bacteriologic illustrations from Cruikshank have been added

A Guide to the Clinical Examination and Treatment of Sick Children By JOHN THOMPSON M D Extra Physician to the Royal Hospital for Sick Children, London, Lecturer on Diseases of Children, Edinburgh School of Medicine In one crown octavo volume of 350 pages with 52 illustrations Cloth, $1 75 net Lea Brothers & Co, publishers, Philadelphia and New York

The author has laid particular stress in this work upon clinical examination and methods of diagnosis, although the other essential features have not been omitted The book is well written, and contains a fair résumé of the existing knowledge of the subject

Transactions of the Indiana State Medical Society Cloth, 537 pp Indianapolis 1898

This volume comprises the transactions of the forty-ninth annual session of this Society, held in Lafayette, Ind, May 5 and 6, 1898 In addition to the usual data found in "Transactions," the following papers presented before the Society are printed "President's Address," "Myths and Medicine," "Cerebral Centers for Pain," "Sudden Blindness," "Trachoma," "Optic Neuritis, Its Relation to Cerebral Disturbances, Toxicity, etc" "Some Points in the Etiology of Typhoid Fever," "Summary of a Report of 100 Cases of Typhoid," "Biology—Its Relations with Medicine as a Factor in Cosmology," "Symptoms, Diagnosis and Treatment of Appendicitis," "Gonorrheal Septicemia," "The Diagnosis of the Different Diseases of the Liver," "Patent Medicines vs Scientific Medicine," "Spinal Irritation," "Tuberculosis—Prevention and Treatment," "Constipation—Its Causes, Effects and Treatment," "Pneumonia," "Auto intoxication," "Of What Value is Alcohol as a Medicine?" "Inflammation from a Surgical Point of View," "Chloroform and Ether Narcosis," "Sarcoma of the Kidney in Childhood," "Nasopharyngitis—Its Causes and Treatment," "The Causation and Treatment of Hay Asthma," "The Mastoid Bone," "Criminal Abortion," "Monstrosity Triplets," "Teratology—Report of a Case," "Some Common Monstrosities," "Toil On, Keep Climbing," "Pus in the Female Pelvis," "The Radical Cure of Hernia," "Report of First Year's Work of Indiana State Board of Medical Examination and Registration," "Climato therapy in Phthisis," "Oral Lesions of Syphilis in Relation to the Public Health," "What Shall We Do About Tuberculosis?" "Personal Observations in Diphtheria," "Excisions of Tonsils"

Transactions of the State Medical Society of Wisconsin Vol xxxii Cloth, 583 pp Madison Tracy, Gibbs & Co , 1898

The reports, papers, etc , in this volume were presented at the fifty second annual session of the Society, 1898, the papers being grouped under the several headings Materia Medica and Therapeutics , Surgery , Practice of Medicine , Neurology , Gynecology , Obstetrics , Pediatrics , Ophthalmology and Otology , Laryngology , State Medicine and Hygiene , Medico legal There are also obituaries of Drs William Meacher, Francis H Bodenius, Lucius M Squire and George D Wilber The "Constitution and By laws" occupy the latter part of the volume, with lists of members, present, honorary and deceased The style of arrangement, the printing and the excellent paper used make this, the thirty second volume of the "Transactions," a credit to the Society

Transactions of the Ohio State Medical Society Cloth Illustrated Pp 556 Edited by P MAXWELL FOSHAY, M D , Cleveland, Ohio Cleveland J B Savage 1898

This volume has to do with the fifty third annual meeting held at Columbus, Ohio, May 4 and 5, 1898, and in general appearance is uniform with former volumes The full membership lists of the societies auxiliary to the State society, omitted last year, are included in the volume The papers presented at the meeting are arranged under the following heads Addresses, surgery, medicine, neurology, gynecology and obstetrics ophthalmology, otology, laryngology and rhinology, rectal and genito urinary surgery, forensic medicine and physiologic chemistry The volume also includes the Constitution and By laws, obituaries, etc

Philippe Pinel of France Science, Philosophy, Courage, Humanity, all in one person Profound honor and gratitude from an American citizen J M B Easter, April 10, 1898 Rev FRANCIS TIFFANY has prepared a memoir of Pinel, which is prefaced by an introduction by Dr J M BARNARD of Milton, Mass

The life story of the great Pinel who struck the chains from the unfortunate at Salpêtrière, is well shown The frontispiece of this pamphlet is a photograph from the painting by Robert Fleury of Pinel's visit to the Salpêtrière

Transactions of the Medical and Chirurgical Faculty of the State of Maryland Paper, 114 pp Baltimore The Deutsch Company, 1898

This volume has to do with the one hundredth annual session, held at Baltimore, April, 1898, also the semi annual session held at Ocean City, September, 1897 The contents comprise Officers, committees and delegates, minutes, president s address "The Country Doctor' , annual address, 'Epidemic Cerebro spinal Meningitis reports rules for the government of the library , lists of presidents, vice presidents active and honorary members

Transactions of the Medical Association of Georgia Cloth Illustrated Pp 274 Published by the Association Atlanta 1898

This volume has to do with the proceedings of the forty ninth annual session, held at Cumberland Island, April 20, 1898 In addition to the usual matter found in "Transactions," it contains a number of charts, explanatory of the papers included in the "Transactions" The papers printed are up to the usual standard of excellence of papers of this Society

SOCIETY NEWS

Cincinnati Academy of Medicine —At the opening meeting, September 19, Dr Johnston exhibited a baby but a few weeks old afflicted with spina bifida and double clubfoot The child had had an imperforate anus, which had been operated upon when the infant was about twelve hours old No muscular tissue was found during the operation The dissections were made entirely through cellular tissue, and the edges of the lower bowel, found opposite the sacral promontory, brought down and stitched to the skin The result has been good, but undoubtedly the child will suffer from the loss of muscular tissue around the new rectum The spina bifida occupies the lower dorsal region and does not contain the cord The regular paper of the evening was read by Dr J A Thompson, on "Nasal Headaches with Illustrative Cases " The causes reported with cases included hypertrophic rhinitis, atrophic rhinitis, either of the above complicated with nasal spur providing the spur presses upon the turbinated bone, deviated septum exerting the same pressure, syphilis including gumma, deep ulcer, and necrosis of the nasal bones, tuberculosis, tumors including polypi, fibroma and sarcomata, foreign bodies, rhinoliths, parasites, perforation of the septum, and granulomatous and purulent inflammations of the accessory cavities of the nose, including the ethmoidal and sphenoidal cells, the frontal sinus and the antrum of Highmore The essayist also stated that very commonly two or more of these affections existed at the same time and that the symptom complained of headache, would not in all probability be relieved unless the nose were rendered free and unobstructed He likewise called attention to the frequency of complicating affections of the trachea, bronchi, larynx, pharynx and nasopharynx He did not wish it to be understood that he thought all headaches, or even a very large proportion of them, were due to pathologic conditions in the nose He did think, however, that headaches accompanied by the symptoms of nasal obstruction, where direct examination showed such obstruction to exist, were in nearly all cases relieved by removing the pathologic conditions existing in the nose Discussed by Drs S E Allen, Vale, Tangeman, and the essayist

Wayne County Medical Society —At the regular meeting of this society, Detroit Mich , September 22, Dr W E Scriber read a paper on "Ten Typical Cases of Typhoid Fever Treated Successfully Without Medicine " The Doctor said he did not feel that he was offering anything new, as he believed the trend of the profession is toward little or no medicine in the treatment of this disease He stated that he had tried the various remedies for typhoid fever in a series of 300 cases with little or no beneficial effect, and in many cases the opposite of what he desired Turpentin and quinin he had entirely discarded as not only worthless but harmful He now confines himself to the use of but four remedies in complicated cases They are cold heat, water and diet. For the moral effect, and to satisfy the friends of the patient a little colored water or powdered chalk is used Diarrhea he said, may be controlled and in most cases arrested by keeping the patient on a small restricted diet, or entire fasting for a few hours [illegible] whey may be given if any food is required During [illegible] cracked ice is beneficial, as it allays vomiting and replenishes the secretions of the body Hemorrhage is met in the same way He said that patients fed on milk had not done well in his hands, as they are more liable to hemorrhage, diarrhea, vomiting and other unpleasant symptoms Constipation, he has found, could be relieved by giving plenty of cold water, if necessary, enemas of pure water The temperature he controls by means of ice compresses applied to the abdomen and back of the neck, the amount of ice used being directly in proportion to the height of fever The Doctor illustrated the success of his treatment by enumerating and giving the histories of ten cases of typhoid fever treated by the method laid down In all cases recovery and convalescence were prompt and rapid

Southern Surgical and Gynecological Association —The approaching meeting of this Association will be held in Memphis, Tenn , November 8, 9 and 10 Papers have been promised by many of the leading surgeons and gynecologists of the country, especially of the South Members of the medical profession are earnestly invited to attend William E B Davis, M D , Secretary

NECROLOGY

CHARLES D SHIRMER, M D , College of Physicians and Surgeons, New York, 1889, died September 15 He was a New York City practitioner

JOHN D KNIEF, M D , Bellevue Hospital Medical College, New York, 1887, died at Liberty, N Y , September 8 His home was in New York City

JOSEPH KUFNER, M D , Bellevue Hospital Medical College, New York, 1882, aged 60 years, died in New York City September 14 He was born in Germany and studied at Vienna and Munich before his arrival in America, thirty five years ago

PHILIP ARTHUR MALLESON, M D , College of Physicians and Surgeons, New York, died at his home in New York City September 19 He was born Dec 25, 1859, at Glens Falls, N Y , and at the time of his death was president of the Harlem Medical Association Besides being a member of many organizations he was well known for his well directed charities

GEORGE TROWBRIDGE, M D , died at his home in New York City, September 10 He was a son of Amos H Trowbridge, president of the Second National Bank, who died in 1881 possessed of considerable wealth Dr Trowbridge was graduated from Yale in 1878, and three years later received his diploma from the College of Physicians and Surgeons, New York, but retired from practice fully ten years ago

ABRAHAM M OWEN, M D , Bellevue Medical Hospital College, New York, 1870, of Evansville Ind , died September 19 He was born in Madisonville, Ky , and early became a member of the AMERICAN MEDICAL ASSOCIATION As one of the organizers of the Pan American Medical Congress and an active promoter of the Mississippi Valley Medical Society he will be recalled by many friends He was a man of great energy, uncommon industry and a most genial companion

T S BELL, M D , Wapell, Iowa, September 16, aged 70 years ——R H Bush, M D , Huntsville, Texas, September 13 ——F Caspar, M D , Warren, Ohio, September 19, aged 82 years ——Harry Chase, M D , Ferron, Utah, September 15, aged 28 years ——Noah T Clarke, M D , Canandaigua, N Y , September 16, aged 81 years ——Henry O Claus, M D , New York City, September 19, aged 72 years ——A M Cooper, M D , Point Pleasant, Pa , September 15, aged 68 years ——Louis T Gruel, M D , Philadelphia, September 19, aged 28 years ——G. W Holcomb, M D , Clinton, Mo ——J S McCain, M D , Lexington, Miss , September 8, aged 70 years ——Albert F Schafer, M D , South Bend, Ind , September 17, aged 35 years ——C I Walker, M D , Powers, Mich , September 11, aged 35 years ——F D Wheelwright, M D , Washington, D C , September 12, aged 81 years

MISCELLANY

New Publication —A new quarterly, *The Psychiater*, $2 a year, has been launched at Hospital, Ill , to contain reports of the scientific work at the Illinois Eastern Hospital for the Insane

Melancholia in Lepers of Iceland —Dr Ashmead has received the following from Dr Jonassen, dated at Reykjavik, Sept 3, 1898 I thank you kindly for the reprint about "The Leprosy Question " As to the melancholia in a leper, I shall remark that about all lepers (when the malady is advanced) are under depression of mind, and I am sure that several cases of melancholia in lepers exist in Iceland

Phlebitis of the Leg in Pneumonia —Da Costa (*Phila Med Jour* , September 10) reports two cases of this rare complication The treatment is the same as for this condition in typhoid fever, rest in bed and elevation of the limb, fomentations to reduce the pain and swelling, laxatives to prevent engorgement of the venous system, and close attention to the heart The patient should be carefully guarded from getting up too soon, and allowed to walk only short distances at first

Historic Research in Maryland —The "Medical Annals of Baltimore," which were edited by the late Dr John R Quinan in 1884, are to be revised by Dr Eugene F Cordell, who has been appointed by the medical and chirurgical faculty to bring the work up to date and issue it as a centennial volume of the faculty in 1900 This is a matter in which all the medical sons of Baltimore, in all parts of the country, can take interest, and many can give their help

More High Balloon Flights —European scientific papers publish interesting accounts of the fifth series of international balloon ascents made in June last Balloons, some manned and some unmanned, ascended simultaneously from various parts of Europe, extending from Paris to St Petersburg, and as far south as Rome An unmanned balloon which started from Paris and dropped in Westphalia, reached a height of about ten miles and recorded a minimum temperature of 83 degrees below zero A balloon carrying Dr Berson, from Berlin, attained an elevation of about 18,000 feet, more than 2000 feet higher than the summit of Mont Blanc The lowest temperature that he experienced was between 10 and 11 degrees below zero

Heroism of an Army Surgeon in India —The following case of an army surgeon's heroism has attracted attention In a recent action on the Indian frontier an officer was wounded in the shoulder by a bullet, and was bleeding to death, the main artery being cut Surgeon Lieutenant Hugo came to his aid The fire was too hot to admit lights to be used to examine the wound, and there was no cover, nevertheless Lieutenant Hugo struck a match and examined the wound The match went out, the fire which had been drawn kicked up the dust all around Having no ligature, he remained three hours holding the vessel under fire the whole time, then picked up the officer, still holding the artery with his thumb and finger, and carried him to a place of safety

Roborant Properties of Spinach —Prominent specialists claim that spinach is the most precious of vegetables, on account of its medicinal and strengthening properties The emollient and laxative virtues of spinach, owing probably to the salts of potash it contains, have been long known It is excellent for the liver and as a consequence freshens the complexion Some vegetables contain a relatively large dose of iron According to Boussingault, the proportion is 0 00074 of iron in 100 parts of French beans, 0 0083 in 100 parts of lentils, and spinach very much more The chemist, Bunge, has proved that spinach and yolk of egg are proportionately richer in digestible iron than all the most renowned ferruginous remedies Its great value and growing importance is shown in the fact that spinach is already an active ingredient in several new and very salable tonics —*Public Health Journal*

Thyroid in Bleeding Fibroids —In the *Medical News* for September 17, Moseley reports the results in five cases and draws the following conclusions 1 That while some patients can take comparatively large doses of thyroid with impunity, others are injuriously affected by small amounts One should therefore begin with minimum doses, i e , three grains daily, increasing the amount slowly, watching its effect on the kidneys and heart 2 Thyroid has a marked influence in bleeding fibroids, in checking excessive loss of blood, and in some cases is followed by a diminution in the size of the growth 3 In appropriate doses, improvement to the general health results probably due to the cessation of excessive loss of blood

Intravenous Saline Injections —Boise (*Med News*, September 10) advocates the intravenous route in postoperative saline injections, as, 1, with proper technic, there is no more danger than by any other route, 2, it supplies fluid to the system most quickly and most certainly, 3, it brings heat directly to the cardiac and arterial ganglia, 4, by this method the stimulating effect of the saline solution on the heart muscle is more immediate and more pronounced He believes the solution should be as hot as can safely be borne, i e , 115 to 118 degrees, and whether the post operative condition of the organs be one of depression or excitation, the heat thus supplied will be beneficial In acute anemia, raising the temperature of the fluid circulating throughout the system will aid in re establishing physiologic conditions

What Did the Rector Mean?—For the sake of the rector, who is young and artless, let his name be unknown But the story is true and it occurred last week, and each woman is busy with its narration There is an organization in the church, what its uses are only the members know, but it is called "The Little Mothers of the Church " Now, this rector was giving out a notice about it the other Sunday, and how a woman could join it, etc And then he made this announcement, which created a flutter and a gasp "Any lady wishing to become a Little Mother can do so by calling on the rector any Friday in his study attached to the church " And a murmuring wave, like a sudden wind in the forest, went over that congregation —*San Francisco News Letter*, *Pacific Med Journal*, September

Trauma as a Cause of Appendicitis —In a paper on this subject (*Medical Record*, September 10), Small concludes 1 That general prevalence of catarrhal conditions of the bowels, perhaps as an accompaniment or result of the grippe, is responsible for a large part of the general increase in prevalence of appendicitis 2 That accidental injuries, strains, and work demanding strong contraction of the abdominal muscles may be held accountable for the greater prevalence of the disease in males 3 That such injuries and strains act by forcing material, loaded with the bacteria which produce appendicitis, from the cecum into the vermiform appendix 4 That in consequence of the irritation of such material, or from some other cause, these germs here find a favorable soil for their multiplication and development 5 That in common with other germ diseases a time of incubation must elapse (for the multiplication of these germs) before symptoms sufficiently marked to prove characteristic of appendicitis can appear 6 That the disease is of growing medico legal importance, as many cases are of traumatic origin, and may therefore give rise to proper suits for damage or valid claims against accident insurance companies

Service of Writs Upon the Insane —In the chancery practice in England, process mst be served on an infant before a guardian *ad litem* can be appointed and this is said to be the general practice in suits against an idiot or lunatic who has been found to be of unsound mind by inquisition Substituted service upon the keeper of an asylum where a lunatic is confined has there been allowed, in equity, when service would be injurious to him In some of the States, service upon a committee or upon a guardian has been held sufficient But as the statutes of Massachusetts concerning the service of writs and subpenas contain no special provisions for service upon infants, or persons under guardianship or of unsound mind, the practice in that State seems to have been to require the same service upon them as upon other defendants And the supreme judicial court of that State says, in the case of Taylor vs Lovering, that it thinks this is the proper practice, because, although service on an infant or a person of unsound mind sometimes would seem to be useless, it often would be difficult to determine whether in fact it would be so or not

Injured Employe Assumes Risk —By retaining a portion of the monthly wages of each employe for medical services, the court of civil appeals of Texas holds in the recent case of the Southern Pacific Company vs Mauldin, the company obligated itself to furnish such services as were practicable and reasonable to each of its employes when sick or injured But this duty, the court says, as it understands the evidence here, was to be discharged, when practicable, by treatment of the patients in the hospital at a certain point, the patients being taken there gratuitously by the company And this being the case, the court considers it immaterial whether a patient could be properly and successfully treated at another place When the company furnished there such treatment as the emergency demanded and was necessary to prepare the patient for transportation to the hospital, by the servants of the company calling to the patient a physician of good reputation residing in the vicinity of the accident, and the patient declined the offer of the company to take him to the hospital, declaring that he was satisfied with the treatment of the local physician, and preferred to remain with him, the court holds that the duty of the company as to the patient was ended, and that he could not recover damages for the mistake of the surgeon to whose care he was temporarily committed, in treating him for sprain ing and laceration of the muscles, instead of for a dislocated hip

Cannot Disclose Incidental Discoveries —In the personal injury case of Nelson vs the Village of Oneida, the plaintiff claimed to have suffered an umbilical hernia, a prolapsus of the uterus, and several bruises, by a fall due to a defective sidewalk But the defendant attempted to show by her physician that she had an umbilical hernia before the accident Its counsel insisted that if the physician discovered the umbilical hernia while attending his patient at childbirth, but did not treat her for it, and the knowledge was not necessary for his guidance in assisting in the delivery of a child, he could disclose it while the court took the position that the very nature of his employment compelled the disclosure to him by the patient and, therefore, it was privileged under the statute The latter provides "A person, duly authorized to practice physic or surgery, shall not be allowed to disclose any information which he acquired in attending a patient, in a professional capacity, and which was necessary to enable him to act in that capacity " Appeal was taken to the court of appeals of New York, and this tribunal now affirms the judgment of the court below, holding that the evidence offered was clearly within the protection of the statute, because the witness acquired the information which the defendant desired to elicit from him while attending the patient in a professional capacity, and the discovery of an umbilical hernia was a necessary incident of the investigations made to enable him to act in that capacity

Insurance in its Earliest Stages —We can discover no earlier recorded instance of insurance against accidents than that mentioned by Livy During the Second Punic War the contractors for delivering corn into Spain stipulated that the Gov ernment should indemify them against loss by tempest. Cicero, too, after his victory in Cilicia, seems to have obtained security against the loss of his booty during its transit to Rome. These instances, however, have not been regarded as genuine cases of insurance by those authorities who assert that only after the revival of commerce in the tenth century did it come into vogue. If this be correct, the first mention of insurance is the establishment in 1310, at Bruges, at the request of the inhabitants, of a chamber of assurance. "The contract of reciprocal insurance was known likewise in Portugal in the fourteenth century, and in the fifteenth, Sept. 10, 1436, King Edward of Portugal writes from Lisbon that the merchant vessels of the English, which had been chartered for the Tangiers expedition, had not been insured owing to the fault of their proprieters, while those of the Portuguese, even of the Royal Navy, were." It is probable, however, that insurance came into use in Italv early in the twelfth century, and was, by the Lombards, transplanted into those countries with which they had commercial dealings. To them, therefore, the invention of insurance, as it is now understood, is generally conceded.—*Pearson's Weekly.*

Statistics of Cutaneous Diseases.—In his presidential address before the recent meeting of the American Dermatological Association (*Jour. of Cut. and Gen. Urin. Dis.*, September), Hyde made a comparison as to cutaneous disorders in this country and abroad, taking as a basis, 500 cases occurring in men, women and children, in the out patient service of public clinics in each of the cities of Paris, New York, Boston and Chicago. The figures show a decidedly greater variation in the character of the tabulated disorders in America. In the 500 cases in New York, 58 different dermatoses were noted; in the 500 in Boston, 54; in Chicago, 48; in Paris, 46. Again, the list of rare disorders tabulated in Paris were less than in each group of 500 cases in the American cities. Of the 500 Paris cases, 114 represented the victims of syphilis, as compared with 46 in the Boston group, 33 in the New York and 170 in Chicago. Chicago patients gave more than four times as many male as females. In New York the sexes were equally divided, and in Paris more than half the patients were women. Paris reported nearly double the number of American cases of alopecia areata; Chicago the larger number of cases of lupus erythematosus and of lichen planus, with a case of pityriasis rubra pilaris. New York excelled in lupus vulgaris, sebaceous gland affections, seborrhoic eczema, and psoriasis, while more than half of the forty five cases of pruritus were from Chicago. Dr. Hyde believes that "the results of this comparison, even though made on a limited scale, are sufficient to indicate clearly that the clinical field for the study of dermatology in our country is in a high degree satisfactory, and that with increased laboratory facilities the day is not distant when American students will no longer deem it requisite to pursue a course of foreign study in order to perfect themselves in this branch of medicine."

Growth of Ether Anesthetization in England.—Dr. Frederick W. Hewitt, anesthetist to the London Hospital, reports that chloroform was administered in only 677 cases out of the 6,657 cases anesthetized at that institution during 1897. He further says that several years ago this anesthetic was in routine use; but experience has tended to somewhat shake our confidence in it for general employment. When such a report is made, coming as it does from a large and important hospital, it seems very significant. A better example of medical conservatism can not, perhaps, be found than in the use of the two great anesthetics. For a long time it has been very evident that ether is the generally safer anesthetic; but convenience, the fact that chloroform is pleasanter to administer and less disagreeable in its after effects, and, above all, habit, seemed for years to blind the eyes of our English brethren to that most important consideration, the greater danger to human life. What though the danger be but slightly greater, is any man justified in risking his patient's life? The gradual change in favor of ether is coming, not alone in England, but on the continent of Europe. In several of the large German and French clinics ether is the usual anesthetic, and in spite of the shockingly large chloroform fatalities annually reported in the *British Medical Journal* and in the London *Lancet*, we believe that there is greater need of this change on the continent; for what American who has visited the clinics of Europe has not been amazed and disgusted at the careless administration of chloroform in some of the most celebrated clinics? It should in justice be stated that there has been in certain parts of our country almost as much prejudice against chloroform as has been shown in favor of it on the other side of the Atlantic. At present it is generally recognized, however, even in Boston, that although ether is the anesthetic to be chosen in the vast majority of cases, chloroform is very definitely indicated under certain conditions and this, we believe, is the proper solution of the matter.—*Philadelphia Medical Journal.*

Scope of Personal Injury Liability.—When a person is injured through the negligence of another, he must use due diligence to obtain proper medical treatment, though the supreme judicial court of Massachusetts says that his duty in this respect is fully discharged by using ordinary care in procuring a reputable physician, and the same care in following his instructions. That the treatment which he obtains is improper will not release the defendant from liability for negligently causing his injury. Nor will the fact that certain medical witnesses testify that blood poisoning is not an ordinary incident, if wounds are dressed in a specified manner, authorize an instruction that the defendant will not be liable for blood poisoning, unless it is the ordinary effect of such a wound, especially so long as there is no evidence that blood poisoning is not a natural result of such an injury as that which the plaintiff received, and no evidence that the wounds which were inflicted on him were not skillfully and properly treated, and so nothing to call for an instruction to be separately given with reference to disabilities resulting from improper treatment. On the other hand, the court holds correct (McGarrahan vs. the New York, New Haven & Hartford Railroad Company) an instruction that if the plaintiff, in the selection of the physician or surgeon, and in compliance with his directions, was in the exercise of reasonable care, the defendant was still responsible in damages for the results of the injury, although those results were more serious than if he had had better treatment. Evidence that one, who practices as a physician and surgeon, attends a patient and gives him professional assistance, the court further holds, justifies a finding that the services were rendered for a pecuniary recompense, to be paid by the patient. And evidence that a sick person is kept and cared for at a private house, other than his home, the court likewise maintains, justifies a finding that he is there upon expense.

Dangers of the Nasal Douche.—Lichtwitz deprecates the routine prescription of the nasal douche in all cases of hypersecretion of the nasal mucous membrane. Irrigation is called for only when the nasal fossa require clearing of pus and crusts, for instance in idiopathic ozena. This affection is mainly limited to the nasal fossa properly so called, and irrigation is in such a case the most fitting form of procedure. An ordinary syringe or enema syringe with suitable nozzle should be used. In all other nasal affections irrigation is inadequate or useless; it is even dangerous. Repeated flooding of the mucous membrane may give rise to olfactory lesions. Antiseptics are highly injurious and pure water is badly borne; the physiologic solutions of sodium chlorid, sodium bicarbonate or sodium sulph are the only harmless liquids. In numerous cases irrigation has caused the sense of smell to be temporarily or permanently diminished or lost Distressing frontal or occipital headache may result, owing to the liquid passing into the sinuses The injection of irritating liquids may even set up inflammation of these cavities The most skillful and careful irrigation is insufficient in many cases to prevent the resulting headache A very grave complication is the penetration of the liquid into the middle ear, suppurating otitis media occasionally supervening In acute coryza, especially in children, douching should never be practiced In one such case known to the author mastoiditis followed irrigation of the nasal cavities The predisposition to otitis is increased after retronasal operations, in particular after ablation of adenoid vegetations For eight years the author has given up all irrigation after pharyngo tonsillotomy, and during that period has met with no case of post operative complication —*British Medical Journal*

Conductors Can Employ Surgeons in Emergencies—It is a mooted question whether or not a railroad company is responsible in any case for the contracts of an employe, not made in the line of his employment, and he having no express authority to make them, and, if so, under what state of circumstances this liability attaches to it However, the supreme court of Arkansas suggests that the weight of authority seems to sustain the doctrine that, in case of an emergency the employment (of a physician, for instance) by the highest railroad official present is the act of the company, and it will be liable for the value of the services rendered to one, in the employ of the company, injured by the running of its trains It says that it may be that it is the legal as well as the moral duty of the company, when an accident happens to a person in its employ, to do all it can to prevent an injury to its servants from having its worst consequences, just as it is its duty to do all it can to prevent the injury in the first instance when informed that the danger is impending But whatever may be the reason, it is a case in which some one should act, and without delay, and the equities are in the idea that the employer is under a greater obligation to do so than any one else not otherwise bound Yet the liabilities should not be extended beyond the exigencies of the occasion, and the extraordinary rule should be most strictly construed, and applied with the greatest caution, and all conditions upon which it is based should appear in every case when it is applied Upon these considerations, the court affirms a judgment in favor of the physician, in the appealed case of the Arkansas Southern Railway Company vs Loughridge, it being of the opinion that the emergency under which the conductor acted in requesting the physician to go and see the injured man (meaning to attend him), a brakeman, was such as to make the act binding upon the company, the charge being reaasonble

Right to Compensation for Attending Paupers—The supreme court of Iowa holds, in the recent case of Lacy vs Kossuth County, that by appointment under the provision of law that each local board of health shall appoint a competent physician who shall be the health officer within its jurisdiction, the appointee becomes simply an officer to assist in the administration of the law and the enforcement of the regulations of the board, and, as such, he is not required to treat the sick in his professional capacity, and he can not be compelled to render assistance to infected persons, simply because he was appointed physician to the board But whatever the board deems best for the safety of the inhabitants, in the matter of assistance and supplies, they may order under the provisions of the Acts of XXII General Assembly and compensation for such service is to be had under the provisions of that enactment Therefore, as the plaintiff in this case was called to the service by the board of health to treat an infected person, the court holds that he was entitled to his compensation although the county may have had a contract with a physician by which such physician undertook to treat all the paupers of the county The fact that the patient in question was a pauper, it adds, was material to the inquiry as to who should pay the bill, and not as to who should perform the service It also holds that there was properly attached to the plaintiff's statement of account a certificate of the board of health that he was employed by it, that he performed the services stated, and that the bill was correct, etc , which certificate became a part of the claim and, as such, was admissible in evidence, though a portion of it referring to the responsibility of the father and to the contract price of the work was rejected On the other hand, the court holds that in an action brought to recover for medical services rendered a poor person, under employment by the township trustees, if the board of supervisors had in fact employed a competent and convenient physician to care for the poor, the trustees were not authorized to employ another simply because they believed the county physician was inattentive, negligent, or incompetent, and that the county would not be liable

Old License but Prima Facie Evidence of Right to New One—The provisions of Section 5 of the Indiana law regulating the practice of medicine, approved March 8, 1897, the supreme court of that State says, materially modify the provisions of Section 2, which, taken alone, would make the possession of a license under the old law the only evidence needed to entitle a person to one under this new law It insists that Section 5 authorizes the State Board of Medical Registration and Examination to do something more than merely inspect the old license before they issue the certificate for a new one and that, under its sweeping provisions, the old license is merely prima facie evidence of a right to the new one The Board, in effect, the court holds, in the case of State ex rel Burroughs vs Webster, June, 1898, is given authority to inquire whether the license was rightfully obtained, and even then, if the applicant is an unfit person to practice medicine, by reason of criminal conduct or immoral character or habits, the Board may refuse a certificate Moreover, after the giving of a certificate, provided no license has been issued upon it, the court further suggests, the Board may after notice and hearing, revoke the same, though they can revoke a license once granted, under the new law only upon the finding and judgment of the circuit court Whether the law is a wise one, is declared to be not for the courts, but for the legislature to say, and the legislature having judged that the safety of public health required the guards that are placed around the practice of medicine by this law, the supreme court says that it is unable to see that the act is not a valid exercise of the police power of the State and it maintains that the statute itself is notice that the legislature has set aside the old licenses and given a reasonable time in which to apply for new licenses in their place and, the applicant for a new license having presented himself before the Board, he must be held to have notice of whatever disposition the Board may make of his application Another point decided is, that that while in some respects quasi judicial the action of the Board is not judicial any more than is the action of a county surveyor in fixing a boundary line or of a county superintendent in giving or refusing a teacher s certificate or the action of numberless other officers and boards in making investigations and decisions in matters committed to them Neither is the circumstance that an appeal is allowed from a decision of the Board deemed an indication that its action is judicial

Death From Insect Stings—According to the *Lancet* of August 27, a fatality from this cause has been reported in the case of a laborer who placed in his mouth a gooseberry which proved to contain a wasp The wasp stung him at the root of the tongue, he went into his cottage and medical aid was summoned, but death ensued in five minutes In this instance death most probably supervened on suffocation, due to intense swelling in the throat and was not due to poison itself Vomiting, fainting, delirium and stupor strongly suggest a highly virulent substance of the nature of a toxin The precise nature of the poison of wasps and bees is not known They possess a poison bag and sting, and the fluid secreted is as clear as water, exhibits an acid reaction and, in fact, contains formic acid But this acid can hardly account for the severity of the symptoms sometimes following a sting Fatal results have indeed occurred, which could only be attributed directly to the toxic action of the sting One of the old fashioned remedies, and we believe a good one, is to apply immediately to the part stung the juice of a raw onion The rationale of this remedy is not clear, the sulphur oil in the onion possibly serving as a palliative The sting, at any rate, if it remains in the wound, should be extracted and the puncture dressed with a little weak ammonia, and afterward a little bromid of ammonia may be added, which frequently serves as a sedative Judging from the great number of wasps which have somewhat suddenly appeared in the rural parts of England, during the recent hot weather, this seasonal pest promises to be of no small dimensions The intense irritation caused in some persons by mosquito "bites" may be properly relieved by the application of ipecacuanha, either the "vinum" or the powdered root, made into a paste with either water or vinegar Spirits of camphor will allay the itching of mosquito bites, and aqua ammonia is supposed to be a direct antidote to the poison of the common insect pests

Societies

The following recent meetings are noted

California —Pasadena Medical Association, September 10

Illinois —Society of Internal Medicine, Chicago, September 10

Iowa —Fremont County Medical Society, Randolph, September 14, Medical Society of the Missouri Valley, Council Bluffs, September 14

Maryland —George's Creek Medical Association, Frostburg, September 15

Massachusetts —Worcester District Medical Society, Worcester, September 14

Missouri —St Louis Medical Society of Missouri, September 24

New York —Academy of Medicine, Syracuse, September 20, Alleghany County Medical Society, September 14, Orange County Medical Society Newburgh, September 13

Ohio —Lucas County Medical Society, Toledo, September 16

Pennsylvania —Cecil County Medical Society, Elkton, September 15, Lancaster City and County Medical Society, September 7, Lebanon County Medical Society, Lebanon, September 13, Lycoming County Medical Society, Williamsport, September 9

Tennessee —White County Medical Society, Sparta, September 9

Texas —Briggs Medical Society, Waxahachie, September 13

Vermont —Connecticut River Valley Medical Association, Bellows Falls, September 20

Cincinnati

Dr S P Kramer, newly appointed brigade surgeon with the rank of major, is on duty at Montauk Point

Dr Charles H Castle surgeon First Ohio Cavalry, is still fighting typhoid fever at Fernandina, Fla

Drs H P Diekmeier and E B Palmer, former internes of the Cincinnati Hospital, have returned from a prolonged course of study in Europe

Detroit

Detroit Medical and Library Association —At the regular meeting September 19, Dr G E McKean read a paper on "Tubercular Meningitis" After reviewing the literature on the subject and giving the pathology, diagnosis and treatment, the Doctor recited the complete histories of three cases occurring in his own practice One of these cases, a child of 8 years, recovered and has since been in good health One other case was that of a young lady 25 years old, but the tubercular deposits in the brain, causing the fatal sickness, were secondary

Health Report for Week Ending September 24 —Deaths 99, under 5 years 43 Births, male 30, female 32 Contagious diseases, Diphtheria, last report 5 cases, 6 new cases reported, 5 recoveries, 1 death, 5 remaining, scarlet fever, 2 new cases, 4 recoveries, no death, 4 now sick, 1 case of smallpox reported, 2 now sick

Washington

Health of the District —The report of the Health Officer for the week ended September 17, shows the total number of deaths to have been 125, of which 64 were white and 61 colored Among the principal causes of death were Nervous diseases, 25, genito urinary, 10, consumption, 15, circulatory, 11, there were 3 deaths from diphtheria, one from whooping cough and 3 from typhoid fever there were 68 cases of diphtheria and 45 cases of scarlet fever under treatment at the close of the week In the annual report of the Health Officer recently submitted to the Commissioners, it is recommended that the salary be increased from $3,000 to $4,000 per annum for the Health Officer, and that a Deputy Health Officer, with a salary commensurate with his duties, be appointed to act as Health Officer when necessity requires Attention is also called to the fact that the clerical force of the department is inadequate, and an increase is recommended It also recommends the appointing of a competent janitor in charge of the smallpox hospital and steam disinfecting plant An increase is recommended for the pound and disinfecting departments, to enable the latter to disinfect premises infected from disease It also recommends an appropriation for abating nuisances and vaccinating the indigent portion of the community The report closes with the important recommendation that the Health Department be provided with an up to date bacteriologic laboratory, and that ashes and sweepings be removed from private premises at public expense

Military Hospital at Ft Monroe —Lieut Col Woodhull surgeon in charge, has reported to Gen Sternberg, that a large military hospital building at Ft Monroe, Va, will be ready for occupation within a few days The hospital will contain 1000 beds, and is specially intended for sick soldiers returning from Porto Rico Surgeon General Sternberg is arranging for other winter hospitals to be located at points to be designated by a Medical Commission

The President Inspects Ft Myer Hospital —President McKinley recently made an inspection tour of the military hospital at Ft Meyer, Va He devoted several hours to the work, inspecting the wards containing about 400 sick, and then directed his attention to the culinary and commissary departments, personally inspecting the kitchen and food furnished the sick He expressed himself as being perfectly satisfied with the management of the hospital

Returned to Duty —Drs J F Moran, James D Morgan, I Bermann and G C Morris, have returned to the city after an extended vacation

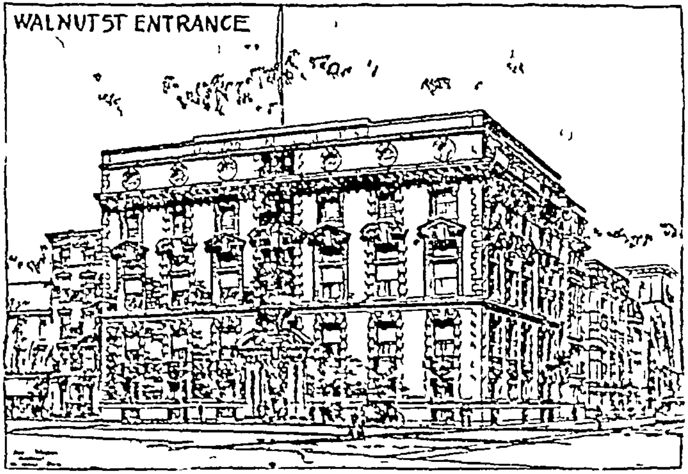
Disease Spread by Flies —The scientific commission consisting of Majors Lee, Vaughn and Shakespeare, of the Medical *Department of the Army*, which has just concluded an inspection of several of the southern camps, has made a report to the War Department to the effect that flies were responsible to a large degree, for the prevalence of typhoid fever among the soldiers The commission visited the camps at Jacksonville, Huntsville, Fernandina and Chickamauga, finding many cases of typhoid fever in each After investigation the commission concluded that the fever had been brought in by the soldiers from their State Camps The members are unanimous in the opinion that the flies, found by the millions in all the camps, were responsible for the prevalence of typhoid fever, and they present many facts to support this conclusion In their report it is stated that the flies fed off the fecal matter from the hospitals, and then at meal time shared the hard tack and bacon of the soldiers While feeding off the fecal matter of the hospital, the fly picked up on his hairy little feet infinitesimal particles containing the germs of typhoid fever and deposited them on the soldier's hard tack and bacon

Deaths from Leaky Gas Fixtures —Quite frequently the coroner is called upon to investigate deaths resulting from gas asphyxiation, and in many instances supposed cases of suicide are found to have met their death from gas escaping from defective brackets It would seem that the proper authorities in Washington should hold somebody responsible for these preventable deaths, just as is done in the case of railroad accidents, explosions and other neglects In the absence of such steps, it might be wise to require owners of property or tenants to keep gas fixtures, keys and pipes in perfect repair, thus limiting or lessening the deaths above cited

Philadelphia

School House Infected —A few years ago several cases of diphtheria developed in the I P Morris School and nearly fifty persons contracted the disease This disease has broken out in this building in previous years and a committee was appointed to investigate It was first thought the disease was conveyed by drinking water, but this was subsequently proven not to be the case The building has been arranged in its present condition by simply bringing two dwelling houses into one, and accommodates 300 children Last year forty cases developed, nine of whom died, and an equal number have died during this latter epidemic The teachers, at the first symptoms of the disease, dismiss the affected children in order that they may return home Many parents very justly refuse to allow their children to attend this school, preferring to contend against the compulsory education law rather than risk exposing them to the contagion The school will doubtless be closed Fourteen cases have also been reported in two other districts of the city

Jefferson Medical College —Students of this institution next year will doubtless be at home in one of the handsomest medical colleges in the country The site is immediately south of the old college building, fronting Tenth and Walnut Streets, being 118 feet long by 110 feet deep, and the new building will be six stories high, of Italian Renaissance style and fire proof



BUILDING OF JEFFERSON MEDICAL COLLEGE

Army Investigating Committee.—Dr W W Keen professor of surgery at the Jefferson Medical College, returned from Europe last week During Dr Keen's absence he was appointed by President McKinley a member of the Army Investigating Committee, but he has, after consideration, declined to accept

Better Education for Physicians —Since the passage of the law in Pennsylvania demanding a strict examination of applicants for those who desire to practice medicine in this State much good has been done toward elevating the profession and suppression of quackery, but there is a determination to raise the standard still higher According to the act of May 18, 1893, governing the subject, one of the specifications was that a common school education should be possessed by the applicants including orthography, reading, writing, arithmetic, English grammar, geography, history of the United States, physiology and hygiene The subjects of physiology and hygiene are to be assigned to the medical examining boards while the other branches will be transferred to and conducted by a committee consisting of persons connected with the public school system It is stated that two preliminary examinations will be annually held in Philadelphia, one during the month of October after the medical schools have opened, and the other preceding the final examination in June Preliminary examinations will also be held in the Western part of the State on the same dates The committee to take charge in Philadelphia will consist of the State superintendent of public instruction, the assistant superintendents of the schools of Philadelphia and several professors in this department Answers to all questions are to be marked and kept on file in Harrisburg It is stated that the Medical Council will accept as satisfactory evidence of a common school education permanent certificates issued by the school department of Pennsylvania, diplomas from colleges, normal schools and other institutions approved by the Council

Huidekoper Resigns —Dr Rush Shippen Huidekoper, formerly of Philadelphia and until recently medical director at Chickamauga Camp, has been detached from his commission in Porto Rico Dr Huidekoper was graduated from the Department of Medicine, University of Pennsylvania in 1877, and practiced medicine in this city, having an office at 111 South Twentieth Street He has been foremost in establishing the Veterinary Department in the University, and lectured in that institution until 1888, when he resigned and went to New York, where he became lecturer in the New York Veterinary School He was for eleven years connected with the National Guard of Pennsylvania as surgeon on the brigade and division staff commanded by General Snowden, and was with the troops during the Homestead riot At present he is in Porto Rico

Dr John Ashhurst, Jr, professor of surgery at the University of Pennsylvania, while on his vacation at Overbrook, near Philadelphia, was attacked with a mild stroke of apoplexy It was hoped at the time that he would sufficiently recover to resume his duties at the coming session, but it is now found that this will not be possible The thousands of students who have gone out from the University will regret to hear of this unfortunate occurrence, for the feeling toward the Professor by all is one of profound respect Besides his position in the University, he is surgeon to the University Hospital, Pennsylvania Hospital and Episcopal Hospital, and is now president of the College of Physicians of Philadelphia At the approaching meeting of the Trustees of the University it is supposed that Dr Ashhurst will be relieved from duty for a sufficient period to recuperate and resume his chair at the University next year

Mortality Statistics —For the week ending September 24 there have been reported to the Board of Health a total of [illegible] deaths This shows an increase of 14 over last week and 21 over the corresponding week of last year Of the total number of deaths, 120 occurred in children under 5 years of age The principal causes of death were Nephritis, 19 cancer, 1[illegible] cholera infantum 10 tuberculosis 40, diabetes 2 heart disease, 33, malarial fever, 1 inanition 8 appendicitis [illegible] marasmus 31, old age 11 suicide 4, sunstroke [illegible] uremia 4

Infectious Diseases —This w[illegible] cases 15 deaths, scarlet fever 5 cases [illegible] 15 deaths Last week Diphtheri[illegible] fever, 15 cases 1 death typh[illegible]

Most of these cases of typhoid fever occurred among the soldiers who had been brought to the city

Jewish Hospital —The thirty third annual report of the Jewish Hospital has just been issued, and shows that during the year ending April 30 there were treated in the wards 736 patients and in the dispensary 11,754 The Hospital Association of which this Hospital is a part also includes the Mathilda Adler Loeb Dispensary, the Home for Aged and Infirm Israelites and the Lucien Moss Home for Incurables The report states that by the death of Lucien Moss a legacy has been left amounting to $200,000 for the erection and maintenance of a home for incurables, to be known as the "Lucien Moss Home for Incurables of the Jewish Faith "

For Federal Quarantine —Owing to the cases of yellow fever recently reported in New Orleans and elsewhere, one of the leading papers here makes a strong plea for the establishment of Federal quarantine, stating that the injurious effects, not only to life but also to commerce, is a sufficient reason why the National Government should have absolute control over all quarantine matters The article then recites the experience of quarantine by local boards of health, shotgun quarantine, etc , and suggests the old idea that the whole matter be transferred to the Marine Hospital Service, which could then manage epidemics of this disease without interference by State or county officials

Condition of the Soldiers in Philadelphia Hospitals —At the present time there are about one thousand soldiers being treated in the different hospitals of this city Three deaths have occurred at the Pennsylvania Hospital within the past few days, and of the 110 soldiers still present in that institution several are yet in a critical condition This Hospital has cared for upward of two hundred soldier patients and these deaths are the first yet reported

Drs Boardman Reed and **Albert Roussel** have both returned from Europe

Dr Laurence Turnbull, who has been for several months at his summer home in Florida, has returned much improved in health

Dr S Weir Mitchell, who is now in Bar Harbor, and Dr Edward P Davis, now at Marion, Mass , are both expected home about October 1

Drs Joseph Price, **W S Stewart** and **John B Deaver**, have been in attendance at the meeting of the American Association of Obstetricians and Gynecologists recently held in Pittsburg

More Soldiers —On the 18th the government transport *Missouri* transferred from Montauk Point 300 sick soldiers to the hospitals of this city On a subsequent day 126 soldier patients were received by them The Red Cross Society has been quite active recently and, up to date, has sent out four trains for the purpose of bringing the soldiers here for treatment

Bequest —Mr Lowber Welch, a wealthy citizen of this place and president of the Union Traction Company, recently sent the following letter to the officials of the Episcopal Hospital "Gentlemen My son, Charles N Welsh, seriously injured seven weeks ago, and being pronounced out of danger by his physicians, it is my wish to commemorate this blessing and to that end inclose my check to your order for $500 to establish a free bed in your hospital for the benefit of ill or injured men while in the service of the Union Traction Company "

CHANGE OF ADDRESS

THE USES OF REMEDIES IN DISEASES OF THE HEART AND BLOOD-VESSELS

Presented to the Section of Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10 1898

BY T LAUDER BRUNTON, M D , D Sc , Edin , LL D , Hon Aberd F R C P , F R S
PHYSICIAN TO ST BARTHOLOMEW'S HOSPITAL
LONDON ENG

It is obvious that the scope of my paper is so large that if I were to deal with it fully I would require to write a text-book, so that I can not do more in the time at my disposal than simply enter upon a few of the most important points I have, therefore, thought it advisable, instead of entering into the details which are usually to be found in ordinary handbooks on the practice of medicine or in special books on cardiac disease, to take up a few points which I regard as the most important and try, if possible, to bring out clearly the general principles of treatment in diseases of the heart and vessels

It is curious to think that the heart which is beating in the bosom of every one began to beat a considerable while before the body had assumed a human shape, and will, with very few exceptions, continue to beat a short time after the individual has forever become unconscious of this world and all its concerns During the whole life of the individual his health, energy and activity, his success in life, his physical force, his mental power and even his moral qualities, all depend to a great extent on the way his heart performs its duty Hardly less important than the action of the heart is the function of the vessels, because, even while the heart is beating regularly and steadily, obstruction to some of the cerebral vessels may transform a man who was far above his fellows in physical strength or intellectual power into a helpless paralytic or demented invalid A study of the means by which the functional activity of the heart and vessels can be maintained or increased is therefore, of the utmost practical importance This has been recognized in every age of medicine, and perhaps there is no movement more characteristic of the physician than that of feeling the pulse of the patient By this simple act the trained finger can discover a great deal regarding the state of both the heart and the vessels and gain much information regarding the indications for treatment Greater perfection in other means of physical diagnosis, and especially in auscultation, have tended to draw attention away from the pulse and direct it rather to the sounds which can be heard in the heart and vessels, so that more thought is now bestowed by many physicians upon actual valvular changes than upon the strength of the cardiac muscle A little consideration will show that this is wrong Many men live with serious organic disease for many years and are hardly conscious of it When I was a medical student, one of my honored teachers had had pericarditis and suffered from great shortness of breath due to adherent pericardium After a lapse of thirty-five years, during which he has continued to do much good work, he seems now to be much stronger and healthier than he was then A similar occurrence takes place when the valves are diseased In his excellent work on diseases of the heart, Sansom says that many who are the subjects of even considerable valvular affections can live a large portion of their lives unconscious that they have any such disease Balfour states that he has seen many cases of aortic incompetency who have suffered from it from thirty-five to forty years, and an old friend of his had suffered from mitral regurgitation for nearly seventy years, yet lived a useful life nearly all that time, and even at the last, his heart was not the first organ to fail A medical man whom I used to see had been rejected for life assurance on account of mitral disease, before the Crimean War, and had been told that he had not two years to live He thought that as his time was short, he might as well see something of the world during it, so he entered the army, served through the Crimean War, saw a great deal of active service afterward, and died only about two or three years ago These instances clearly show that considerable valvular disease may have little effect in shortening life or producing serious symptoms But the case is very different when we come to consider the muscular walls of the heart, for any weakness in them not only enfeebles the circulation at once, but will secondarily produce valvular incompetence The mitral and tricuspid valves are only large enough to close orifices of a certain diameter, and when these orifices become larger, as they do from enfeeblement of the cardiac muscle, the valves are not able to close the auricular and ventricular openings, and regurgitation takes place

Weakness of the heart is not an absolute, but only a relative term, and however strong the heart itself may be, the limit of its power may be reached The ancient Greek who carried the news of the battle of Marathon to Athens must have had a very powerful and healthy heart in order to do so, but even he overstrained it and fell dead at the conclusion of his task The young American who performed a similar feat a few years ago showed himself either stronger or more fortunate than the hero of old, yet he must have felt the unpleasant symptoms of cardiac strain These symptoms are known to almost every one because in ordinary people who are out of training a short run to catch a railway train or steamer more especially if a portmanteau or bag be carried will bring on tightness and oppression across the chest rapid difficult and gasping breathing giddiness and muscular [illegible]ness so that the person may be unable to stand In feeble or elderly men these symptoms may be [illegible]ated with a sense of impending death, and death

Most of these cases of typhoid fever occurred among the soldiers who had been brought to the city

Jewish Hospital —The thirty third annual report of the Jewish Hospital has just been issued, and shows that during the year ending April 30 there were treated in the wards 736 patients and in the dispensary 11,754 The Hospital Association of which this Hospital is a part also includes the Mathilda Adler Loeb Dispensary, the Home for Aged and Infirm Israelites and the Lucien Moss Home for Incurables The report states that by the death of Lucien Moss a legacy has been left amounting to $200,000 for the erection and maintenance of a home for incurables, to be known as the "Lucien Moss Home for Incurables of the Jewish Faith"

For Federal Quarantine —Owing to the cases of yellow fever recently reported in New Orleans and elsewhere, one of the leading papers here makes a strong plea for the establishment of Federal quarantine, stating that the injurious effects, not only to life but also to commerce, is a sufficient reason why the National Government should have absolute control over all quarantine matters The article then recites the experience of quarantine by local boards of health, shotgun quarantine, etc , and suggests the old idea that the whole matter be transferred to the Marine Hospital Service, which could then manage epidemics of this disease without interference by State or county officials

Condition of the Soldiers in Philadelphia Hospitals —At the present time there are about one thousand soldiers being treated in the different hospitals of this city Three deaths have occurred at the Pennsylvania Hospital within the past few days, and of the 110 soldiers still present in that institution several are yet in a critical condition This Hospital has cared for upward of two hundred soldier patients and these deaths are the first yet reported

Drs Boardman Reed and **Albert Roussel** have both returned from Europe

Dr Laurence Turnbull, who has been for several months at his summer home in Florida, has returned much improved in health

Dr S Weir Mitchell, who is now in Bar Harbor, and Dr Edward P Davis, now at Marion, Mass , are both expected home about October 1

Drs Joseph Price, W S Stewart and **John B Deaver**, have been in attendance at the meeting of the American Association of Obstetricians and Gynecologists recently held in Pittsburg

More Soldiers —On the 18th the government transport *Missouri* transferred from Montauk Point 300 sick soldiers to the hospitals of this city On a subsequent day 126 soldier patients were received by them The Red Cross Society has been quite active recently and, up to date, has sent out four trains for the purpose of bringing the soldiers here for treatment

Bequest —Mr Lowber Welch, a wealthy citizen of this place and president of the Union Traction Company, recently sent the following letter to the officials of the Episcopal Hospital "Gentlemen My son, Charles N Welsh, seriously injured seven weeks ago, and being pronounced out of danger by his physicians, it is my wish to commemorate this blessing and to that end inclose my check to your order for $500 to establish a free bed in your hospital for the benefit of ill or injured men while in the service of the Union Traction Company"

THE USES OF REMEDIES IN DISEASES OF THE HEART AND BLOOD-VESSELS

Presented to the Section of Materia Medica, Pharmacy and Therapeutics at the Forty-ninth Annual Meeting of the American Medical Association held at Denver, Colo., June 7-10, 1898.

BY T. LAUDER BRUNTON, M.D., D.Sc., Edin., LL.D., Hon. Aberd., F.R.C.P., F.R.S.
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL
LONDON, ENG.

It is obvious that the scope of my paper is so large that if I were to deal with it fully I would require to write a text-book, so that I can not do more in the time at my disposal than simply enter upon a few of the most important points. I have, therefore, thought it advisable, instead of entering into the details which are usually to be found in ordinary handbooks on the practice of medicine or in special books on cardiac disease, to take up a few points which I regard as the most important and try, if possible, to bring out clearly the general principles of treatment in diseases of the heart and vessels.

It is curious to think that the heart which is beating in the bosom of every one began to beat a considerable while before the body had assumed a human shape, and will, with very few exceptions, continue to beat a short time after the individual has forever become unconscious of this world and all its concerns. During the whole life of the individual his health, energy and activity, his success in life, his physical force, his mental power and even his moral qualities, all depend to a great extent on the way his heart performs its duty. Hardly less important than the action of the heart is the function of the vessels, because, even while the heart is beating regularly and steadily, obstruction to some of the cerebral vessels may transform a man who was far above his fellows in physical strength or intellectual power into a helpless paralytic or demented invalid. A study of the means by which the functional activity of the heart and vessels can be maintained or increased is therefore, of the utmost practical importance. This has been recognized in every age of medicine, and perhaps there is no movement more characteristic of the physician than that of feeling the pulse of the patient. By this simple act the trained finger can discover a great deal regarding the state of both the heart and the vessels and gain much information regarding the indications for treatment. Greater perfection in other means of physical diagnosis and especially in auscultation have tended to draw attention away from the pulse and direct it rather to the sounds which can be heard in the heart and vessels, so that more thought is now bestowed by many physicians upon actual valvular changes than upon the strength of the cardiac muscle. A little consideration will show that this is wrong. Many men live with serious organic disease for many years and are hardly conscious of it. When I was a medical student, one of my honored teachers had had pericarditis and suffered from great shortness of breath due to adherent pericardium. After a lapse of thirty-five years, during which he has continued to do much good work, he seems now to be much stronger and healthier than he was then. A similar occurrence takes place when the valves are diseased. In his excellent work on diseases of the heart, Sansom says that many who are the subjects of even considerable valvular affections can live a large portion of their lives unconscious that they have any such disease. Balfour states that he has seen many cases of aortic incompetency who have suffered from it from thirty-five to forty years, and an old friend of his had suffered from mitral regurgitation for nearly seventy years, yet lived a useful life nearly all that time, and even at the last, his heart was not the first organ to fail. A medical man whom I used to see had been rejected for life assurance on account of mitral disease, before the Crimean War, and had been told that he had not two years to live. He thought that as his time was short, he might as well see something of the world during it, so he entered the army, served through the Crimean War, saw a great deal of active service afterward, and died only about two or three years ago. These instances clearly show that considerable valvular disease may have little effect in shortening life or producing serious symptoms. But the case is very different when we come to consider the muscular walls of the heart, for any weakness in them not only enfeebles the circulation at once, but will secondarily produce valvular incompetence. The mitral and tricuspid valves are only large enough to close orifices of a certain diameter, and when these orifices become larger, as they do from enfeeblement of the cardiac muscle, the valves are not able to close the auricular and ventricular openings, and regurgitation takes place.

Weakness of the heart is not an absolute, but only a relative term, and however strong the heart itself may be, the limit of its power may be reached. The ancient Greek who carried the news of the battle of Marathon to Athens must have had a very powerful and healthy heart in order to do so, but even he overstrained it and fell dead at the conclusion of his task. The young American who performed a similar feat a few years ago showed himself either stronger or more fortunate than the hero of old, yet he must have felt the unpleasant symptoms of cardiac strain. These symptoms are known to almost every one, because in ordinary people who are out of training a short run to catch a railway train or steamer, more especially if a portmanteau or bag be carried, will bring on tightness and oppression across the chest, rapid, difficult and gasping breathing, giddiness and muscular weakness so that the person may be unable to stand. In feeble or elderly men these symptoms may be associated with a sense of impending death and [illegible] indeed may actually occur In such cases we find that moderate exertion in persons who are healthy but otherwise out of training, produces symptoms similar to those which occur in men of exceptional health and training, like that of the athletes of Athens, after severe strain But when the heart is feeble and fatty from imperfect nutrition, such as occurs from the chronic abuse of alcohol, or from atheromatous change in the coronary arteries, and especially when the heart thus degenerated has extra work thrown upon it by valvular disease, we find that slight movements, such as that of crossing the room, of getting up, or even of sitting up in bed, may bring on symptoms of cardiac distress similar to those which occur after a run to the train in middle-aged gentlemen, or after a run of many miles in athletes What I have just said is, I think, sufficient to prove the statement with which I started, namely, that cardiac weakness is a relative term, and expresses the power of the heart, not absolutely, but only in relation to the work that it is called upon to perform Probably there is not one in a hundred thousand, perhaps indeed not one in several millions of men, however young, strong or athletic, who could at a moment's notice start on a race such as that from Marathon to Athens and run it successfully In order to do so previous training is necessary, and the science of such training is to accustom the heart to excessive exertion by gradually increasing the work which it has to do, while at the same time the other organs of the body are kept in a healthy condition, so that the heart may receive a proper supply of healthy blood and its nutrition be thereby increased The best example of training is the classic one of Milo, the wrestler of Croton, who is said to have succeeded in carrying a full-grown bull upon his shoulders by beginning to carry it when it was a new-born calf and continuing to carry it every day afterward In this way, it is said, the athlete's strength gradually increased in proportion to the weight of the calf If training, then, be the method of bringing an ordinary healthy heart up to the mark required for excessive physical exertion, the same method ought to be successful in bringing the heart enfeebled by disease up to the healthy standard

This, I believe, is the truth, and of all agents for remedying cardiac weakness there is none so good as that of training The training must be adapted to the condition of the heart, and the amount of exercise given to a feeble, fatty heart must be very little indeed, and when even slight movements give rise to cardiac distress, we must insist upon absolute rest It is sometimes difficult to get this injunction carried out, for active people insist upon getting up and moving about the room, even when such movements cause distress But here the physician must insist that absolute rest in bed shall be maintained and that the whole strength of the patient shall be devoted to the recuperation of his heart One good rule is that the heart shall not be allowed to make a single extra beat that can be avoided If the patient rises in bed his heart will probably beat from five to ten times in a minute more than if he lay quiet, and if it does this for five minutes it has done from twenty-five to sixty beats too much Sometimes patients will grumble, but they may occasionally be comforted by simply reminding them that their condition is not nearly so bad as if they had broken their thigh bone, for then they would have been put up with a splint, unable to move for many weeks, and very likely have been suffering pain, while their cardiac disease is producing them no pain whatever Indeed, I have sometimes threatened patients to put them up in a long splint, as if they had a broken leg, when I find them rebelling against the enforced rest which is necessary for their recovery I do not think I can speak too strongly regarding the necessity for absolute rest in bed in cases of cardiac distress I often remind patients that they must treat a strained heart as they would a sprained ankle, and remember that just as the least extra movement will bring on a pain in the ankle, so it will increase the distress in the heart, while each increase still further prolongs the time necessary for recovery

But here another difficulty meets us By keeping the patient so quiet we no doubt lessen the work the heart has to do, but we diminish at the same time the circulation through the stomach, liver, intestines, kidneys and muscles, and we thus tend to a certain extent to interfere with the elaboration of healthy blood which is required for the efficient nourishment of the heart Here massage comes in, and when this is skilfully applied, it not only increases the circulation through the various organs of the body, but while doing so it gives the heart rather less than more to do For when the patient is left to himself the heart has to drive the blood onward through the whole circulation, but when the masseur is at work he moves the venous blood along the veins, the lymph along the lymph spaces and lymphatics, so that his hand is really a kind of accessory venous and lymphatic heart At the same time it actually lessens the work to be done in the muscular arteries, for Dr Tunnicliffe and I found that massage of the muscles causes the blood to flow through them much more quickly than when they are at rest We see, then, that in the worst cases of cardiac distress the chief remedies are absolute rest and massage But there is a long interval between this condition and that of ordinary health, which must be filled up by gradually increasing movements These movements have of late years received a great deal of attention, more especially from Ling in Sweden, Schott of Nauheim, and others The essence of these movements is that they must be slow, gentle, and gradually increased against resistance, that they shall not cause the patient any distress, but only call upon the heart for such work day by day as it is well able to do But before the patient has reached this stage where he is able to take ordinary exercise, another system of treatment, namely baths, may be employed to assist the action of the exercises In the treatment which is so successfully employed at Nauheim the baths contain chlorids of sodium and calcium, the proportions being 10 per 1000 of chlorid of sodium at the commencement, gradually raised to 30, and of chlorid of calcium 2 per 1000, gradually raised to 3 or even 5 per 1000 At Nauheim the waters contain carbonic acid, but this may be artificially supplied by means of bicarbonate of sodium and hydrochloric acid, or tablets specially prepared for this purpose

The effect of these baths is to stimulate the skin and increase the flow of blood through it, while at the same time a reflex influence is exerted upon the heart through the vagus, by which the pulse is slowed It is evident, by dilating the cutaneous vessels, the effect of the bath upon the skin is somewhat similar to that of the masseur upon the muscles, that is, in both cases the bed through which the blood has to flow becomes wider, and the resistance to the action of the heart is consequently diminished Where the tension is great it may be still further diminished by the use of nitrites or substances having a similar reaction But the most important effect of the baths is probably a reflex one upon the heart, and perhaps I may make this effect more clear by a comparison with athletic feats To walk a thousand miles in six weeks can hardly be regarded as any feat at all, but to walk a thousand miles in a thousand hours is a very different thing indeed, and may be regarded even now as beyond the capacity of most men There is no more actual work involved in walking twenty-four miles in one day than in walking twenty-four miles in twenty-four successive hours, one mile every hour The difference between the two is the shortness of time allowed for rest and recovery between each period of exertion in the latter When this time is further shortened, as it is in walking a thousand half miles in a thousand half-hours, the difficulty becomes incomparably greater It would probably be almost impossible for any one to perform this feat by walking a mile at the beginning of each half-hour, but in order to increase the interval for rest, one mile is done at the end of one half-hour and the next mile at the beginning of the next Supposing that a man walks four miles an hour, or what is equivalent to it, one mile in a quarter of an hour, he would only have a quarter of an hour's rest between each successive mile if he walked it at the beginning of each half-hour But by walking two miles together he is able to obtain half an hour's rest, and it is the prolongation of the rest which enables the man to go through with the feat Now, the action of the heart is like that of the athlete who has very short periods of rest between his periods of action, and just as the athlete's work is rendered more difficult by shortening his periods of rest, so is that of the heart by increasing the rapidity of its pulsations For just as the athlete will take about the same time to cover his mile whether he be walking twenty-four miles a day, one mile in each hour, or half a mile in each half-hour, so the heart takes about the same time to perform its systole whether it be acting quickly or slowly Increased rapidity of the pulsations, therefore, means a shorter time for rest and consequent loss of time for recuperation The inhibitory fibers of the vagus, which slow the heart, are the nerves which tend to increase its nutrition, and when they are cut through and the heart is allowed to beat more quickly, it is very apt before long to undergo degeneration It is, therefore, evident that any means by which we can stimulate the vagus and slow the heart is likely to aid us in restoring its power This is the effect which baths seem to have, and they probably act reflexly on the vagus through the nerves of the skin

But we have, in addition, various drugs which stimulate the vagus roots in the medulla oblongata or the terminal endings in the heart itself The number of these drugs is very great, and very many of the arrow poisons and ordeal poisons employed by savages act on the heart in this way

Among them may be mentioned the active principles of digitalis, strophanthus, erythrophleum, convallaria, adonis vernalis antiar, tanghinia, hellebore black and green, oleander squill, manganja, carravol, vao and cactus, but among these the most important are certainly digitalis and strophanthus These drugs not only slow the heart, but they increase the energy with which it contracts The energy may be still further increased by a combination of strychnin or nux vomica with the drugs already mentioned, for while they appear to act chiefly on the muscular fiber, strychnin exerts its stimulating action on the motor ganglia of the heart By the combined use, then, of rest, massage, graduated exercises, baths and cardiac tonics, the heart may be brought from a condition of extreme weakness to one of moderate strength

And then comes in the use of another system of training which is usually associated with the name of Oertel The essence of this consists in gradually increasing the work that the heart has to do by making the patient walk farther and farther along paths of gradually increasing steepness, so that at the end of the treatment he will be able to walk a considerable distance and up a pretty steep incline This treatment, however, requires careful supervision, lest at any time the patient overtax his strength, and the supervision should be exercised from day to day, because the health and strength of a man may vary very considerably in two successive days, not from any change in the heart itself, but from changes in other organs and more especially in the digestive or eliminative organs Attention to these is most essential in diseases both of the heart and vessels, but to enter fully upon this subject would take me too far, and I must conclude this paper, which I fear is already too long, by simply mentioning the great use of cholagogues, purgatives and alteratives, such as iodid of potassium, in diseases of the heart and vessels, more especially in atheroma, which, by affecting the coronary arteries, leads to disease of the heart itself The utility of iodid of potassium is very great, but sometimes it must be administered in large doses, and frequently I believe the full advantage is not obtained because the doses are not sufficiently large

To resume shortly what I have said in this paper, the main risk in cardiac disease is from feebleness of the muscular wall of the heart, and the chief remedy is to lessen the work to be done till it is not excessive even for the most feeble heart, to slow the heart's action so as to give it time for rest, and to train the heart by graduated exercises until it is able to meet all the ordinary, or perhaps even all the extraordinary, demands upon it

---

THE USE OF MORPHIA IN BRIGHT'S DISEASE

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo , June 7-10 1898

BY SIDNEY RINGER, M D , F R S

LONDON ENGLAND

Few opinions are more firmly held or more dogmatically taught than that opium must not be given to patients with albuminuria or Bright's disease The more extreme upholders of this doctrine teach that the presence of albumin in the urine, even when the kidneys are not diseased, as in cases of fever, prohibits the use of opium Many years of careful investigation of this subject convince me that this opinion is wrong I avail myself of this opportunity to again draw attention to this subject Several writers in America and England have recorded their experiences that opium either by the mouth or hypodermically may be administered, not only without danger but with great advantage, to some patients with uremia Dr Loomis ("Diseases of Respiratory Organs, Heart and Kidneys,' 1875) states that he has employed morphia hypodermically in puerperal eclampsia with marked success He says that morphia may be given hypodermically to some, if not all, patients with acute uremia without endangering life He states that the almost uniform effect of morphia so administered is 1, to arrest muscular spasm by counteracting the effect of the uremic poison on the nerve centers, 2, to establish profuse perspiration, 3, to facilitate the action of cathartics and diuretics He has given half a grain of morphia hypodermically to patients completely comatose, with uremia, with benefit Austin Flint ("Clinical Lecture," *New York Medical Journal*, reported in *Medical Times*, April, 1880) states that uremic convulsions in connection with hard contracted kidneys are well treated with hypodermic injection of morphia There is no question in his mind, he says, that the administration of morphia in pretty full doses is of considerable service in quite a number of cases of uremic poisoning with nausea, tremor, impaired vision, etc Roberts Bartholow ("Treatment of Diseases by the Hypodermic Method") asserts that in the treatment of uremic convulsions considerable doses of morphia are demanded, to an adult half a grain may be administered at once, and repeated so that as much as two grains may be injected within a few hours in severe cases Stephen Mackenzie (*Lancet*, Aug 3, 1889) reports some cases of uremia treated with hypodermic injections of morphia One patient with paroxysmal dyspnea, with weak heart was relieved by one sixth of a grain of morphia Another case with breathlessness, irregular action of the heart and headache was greatly relieved by the same treatment, the patient obtaining refreshing sleep the first time for a long period He has benefited patients with renal asthma by hypodermic injections, also removed headache He refers to two cases reported in the *British Medical Journal*, March 16, 1888, suffering from uremic convulsions, both of whom recovered after the hypodermic use of one grain of morphia Robert Park (*Practitioner*, Vol xxiv, 1880) recommends this treatment in uremic insomnia and orthopnea Powell (*British Medical Journal*, 1885) injected one-twelfth grain of morphia into a child 6 years old suffering from uremic convulsions, due to acute nephritis, following scarlet fever The convulsions subsided, there was no recurrence and the child recovered

Osler writes concerning uremia, 'for the restlessness and delirium morphia is indispensable Since its recommendation by Stephen Mackenzie in uremic states, some years ago, I have used this remedy extensively and can speak of its great value in these cases I have never seen ill effects or any tendency to coma follow" My observations entirely confirm these statements and yet the use of morphia in Bright's disease is denounced with little less than horror by most practitioners, though they all confess that they have never tried it, that, indeed, they dare not do so Morphia hypodermically employed is of conspicuous benefit in the shortness of breath of uremia This may be due to different causes With some patients the compensatory hypertrophy gives way and they suffer from cardiac dyspnea, in all respects similar to that from valvular defects with insufficient compensations, notably, sleep in aortic regurgitation The paroxysmal shortness of breath prevents sleep, on falling asleep they are soon wakened by distress of breathing The patient is compelled to start up in bed, often throws his legs out of the side of the bed panting for air, or the sleep may be distressed and harassed by Cheyne-Stokes breathing This distressing condition, whether due to deficient compensation, in Bright's disease or to valvular defects, is almost invariably relieved by hypodermic injection of morphia, and several hours' refreshing sleep are secured, to the great relief and comfort of the patient, who on the following day is refreshed, takes and digests and assimilates his food better Morphia can scarcely be too highly commended in such a condition, and although it does not cure, it delays the end and greatly lessens the distress of the declining days of life

Uremic asthma, again, yields promptly to hypodermic injection of morphia On the other hand, persistent distress of breathing may be due to dropsy, the lung being hampered by an abundant serous effusion into the cavity of the chest I need hardly say that such a condition is not improved by the use of morphia

The headache and sleeplessness occurring in uremic patients can generally be removed by the hypodermic injection of morphia I have not given this treatment in uremic convulsions or coma, but I have largely used it in many cases of uremia with other troubles, and am sure that morphia may be given to such patients with every prospect of benefit and no risk of harm

THE PLACE OF HYDROCHLORIC ACID IN THE TREATMENT OF DISEASES OF THE STOMACH

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo , June 7 10 1898

BY BOARDMAN REED, M D
PHILADELPHIA PA

The time has come for a definite and precise statement of what hydrochloric acid can do in the treatment of stomach diseases—when and how it is useful as well as when and how it can be harmful Riegel, in his recent work[1] very pertinently remarks 'While formerly HCl was prescribed in nearly all dyspeptic conditions, its employment has of late been essentially limited, since it has been recognized that it is by no means true, as was once assumed, that in almost every form of dyspepsia a lack of HCl exists" There is much other testimony to the effect that even among the aggravated stomach conditions for which the advice of a specialist is sought, an excess of this acid is very often found in the gastric juice Could all cases of gastric derangement, including the earlier stages of catarrhal affections, be brought to the test of a chemical analysis of the stomach contents, it is probable that those with either a normal or excessive secretion would be largely in the majority And none of these require the administration of HCl as a medicine Indeed, it is capable of doing pronounced harm in all such cases We should expect, a priori, that to introduce this active drug artificially into stomachs which already secrete it in too large quantity, would intensify the depressing and painful symptoms of hyperchlorhydria Experience has abundantly shown that this result usually follows in such cases when the drug is administered in considerable doses

The well-known antiseptic power of HCl might tempt one to give it in the numerous cases in which, despite the presence of a normal percentage of this acid in the gastric juice, the patients suffer from eructations of gas as a result of fermentation in the stomach, and (as still more frequently happens in cases with a normal or over-abundant secretion of gastric juice) are plagued with a large amount of intestinal flatulency Indeed, this remedy is administered every day by excellent physicians in these conditions, not after having actually learned through a gastric analysis that a full proportion of HCl is secreted, but upon a venture, assuming that there may be a deficiency, and if not, that in any case the drug is antiseptic and must do some good Just here is where the mistake is made To administer HCl in cases in which it is not deficient, is not only to do no possible good but generally to do harm, and for these reasons This drug, as has been pointed out by the writer in previous papers,[2] acts even in small doses as a decided stimulant to the gastric glands, and when long continued rarely fails to increase largely their activity, except in gastric atrophy or cancer This property which renders it so useful as a remedy when the gastric juice is insufficiently secreted, becomes a cause of injury in the opposite condition Therefore, HCl taken into a stomach already supplied with it, and the stomach contents after meals being thus as acid as nature intended them to be, must not only produce at the time an excessive degree of acidity with all the harmful results, especially to digestion in the small intestine which this implies, but if administered often enough may easily set up a more or less permanent hyperchlorhydria

But it may be urged that we might well risk some over-acidifying of the gastric juice and the resulting impairment of intestinal digestion, if by this means we can lessen fermentation in the stomach Unfortunately, however, in the cases in which there is no deficiency of HCl, very little, if any, antiseptic action can be demonstrated as a result of its administration In the acid gastritis described by various authors in Germany and France, and especially in recent treatises by Hemmeter[3] and VanValzah and Nisbet[4] in this country a condition which my own experience has shown to be very common and the one most often present, when a normal or excessive proportion of HCl is found associated with much fermentation, the gas forming bacteria seem to acquire a tolerance for the HCl and to thrive in spite of it At all events, the fact that even a very great excess of HCl in the human stomach does not prevent fermentation, has been made familiar to the writer by a large number of observations Riegel has lately called attention to it without attempting to account for it In his work already referred to, he says 'That the presence of free HCl in the stomach contents is no hindrance to the development of an abundant gaseous fermentation is a long since established clinical fact, which through the researches of Kuhn and Strauss has been given a further support It has been proved that the HCl of the gastric juice under the existing conditions has absolutely not the disinfecting properties against the yeast fungi which has been established, for it is in a pure solution of the drug, or in artificially prepared gastric juice, but on the contrary, the view always maintained by us has been confirmed, that when stagnation exists the preferred soil for the gaseous fermentation is afforded by just those cases which show a normal or over-large amount of HCl Some experiments recently reported to the Hospital Medical Society by Toinot and Brouardel and published in the *British Medical Journal*, show that the bacillus coli can be made to acquire a tolerance for arsenious acid even in strong solutions They succeeded in training this bacillus to grow well in bouillon containing three grams to the liter of arsenious acid Then why may it not be that bacteria in the stomach gradually become accustomed to the presence of HCl until finally even a large excess of it does not affect them ? At all events the gas forming micro-organisms are found to flourish in the stomach even when there is present a very large excess of HCl, and in these cases when they have become chronic, it is the rule to have grievous complaints of flatulency, both gastric and intestinal with an endless train of nervous symptoms, including especially mental depression and insomnia, along with usually constipation

What has already been said as to the contra indications for HCl tells in a large measure where and how it can be helpful in the treatment of gastric affections There are a few prominent gastro enterologists who seem to place little reliance upon this drug in any case, but the writer has found it of exceeding value, not only as a palliative in cases of atonic dyspepsia, but also as a reconstructive tonic in cases of chronic gastric catarrh, which have not yet progressed to entire atrophy of the glands In fact, the results which have followed its administration in my practice (usually in combination with pepsin) fully warrant me in assigning to it in the therapeutics of all stomach diseases characterized by hypopepsia (except cancer and atrophy) a place second only to diet and the mechanical treatments, including especially abdominal massage My note books contain the histories of a large number of cases in which the administration of HCl for from one to four months, more or less continuously has been followed by a most notable and apparently permanent increase in the secretion of the gastric glands In the majority of my cases massage and the use of pulleys or other suitable exercise for the strengthening of the trunk muscles, were also employed as a regular part of the treatment, and the results in these can not be cited as proving the efficacy of any one of the curative measures relied upon The cure of the patient having been naturally the first consideration, the treatment has not been limited to any one agency, no matter how valuable A large amount of evidence has thus accumulated which, it must be admitted, is inconclusive in so far as concerns the relative value of the various remedies used

But, fortunately for the purposes of this paper, some of my hypopeptic patients found it impracticable to take massage, and at the same time unable for various reasons to carry out with any regularity the directions as to methodical exercise, and the marked gain in digestive power acquired by these must be credited mainly to the medicine taken

Wegele and Hemmeter[5] among recent authors bear witness to the powers of HCl as a stomachic or stimulant to the peptic glands Hemmeter also quotes Riegel, Reichman and Mintz as having reported cases of achylia gastrica in which the restoration of the secretion of HCl was effected by a more or less prolonged dosage with the same acid Hemmeter gives 20 drops of the diluted HCl in appropriate cases in two ounces of water every half hour, beginning fifteen minutes before meals and continuing it till half an hour after the meal He has [illegible] lent results from this method [illegible] the motor function of the stoma[illegible] as well as the glands, a view which my own experience confirms My practice has been to give much smaller doses I direct the patient usually to begin with a dose of four or five drops of the dilute HCl given after each meal in this way The amount prescribed, which is gradually increased, if necessary, up to ten, or exceptionally even to twenty drops, is added to half a goblet of water, which the patient is directed to take in small sips at frequent intervals during an hour or hour and a half In cases of complete or nearly complete anacidity the sipping of the diluted acid is begun immediately after the meal, but in other cases not till the meal has been over for half an hour In this way the amylaceous portions of the food are given time for the action of the saliva I was led to adopt this gradual method of administering the acid through having observed a number of cases with absence of free HCl in which the patients complained of a marked burning in their stomachs after taking quite small doses of the remedy This apparent intolerance of the drug was overcome entirely by having it taken gradually in small sips, and the results eventually were quite as gratifying as in other cases in which no such disagreement had occurred Except in those cases, where in spite of deficient or absent HCl secretion there had been demonstrated a normal proportion of pepsin or of pepsinogen, I have usually combined with HCl a moderate amount of a good preparation of pepsin in the form of a glycerole When owing to the exigencies of a busy practice the quantitative tests have included the total acidity and amount of free HCl only, pepsin has generally been added to the mixture, and the very large proportion of such cases in which the digestive power has decidedly increased insomuch that the patients, after a time, were able to do without stomach remedies, has led me to suspect that these doses of pepsin may, like HCl itself, exert a real curative influence, acting to some extent as a stimulant to the cells which secrete pepsinogen In the cases, reports of which are given below, no very severe restrictions of the diet were imposed, though hot or fresh bread, fried articles, sugar, nuts, vinegar, the sourer fruits, especially uncooked, and shellfish, except oysters in their season, were excluded, and the patients were enjoined to eat slowly, using their saliva to moisten all starch foods, and to drink either nothing or very sparingly at meals

Case 1 —Lady aged 36, resident in New York, while on a visit to Philadelphia came under my care on account of chronic indigestion with much fermentation, constipation, anemia, irregular menses, impaired sleep and cardiac palpitation She gave a history of having suffered in a similar manner for several years, and of having had more or less trouble with her stomach for twelve years Had formerly had much pain after meals, and for this had been directed to take freely and continuously tablets made up mostly of sodium bicarbonate about 5 grains in each She began by taking one every hour, or 16 a day, but finally reduced them to 8 daily These were continued with little or no medical oversight for three years, until they markedly disagreed by causing nausea External examination when this patient came under my care in December, 1896, showed the right kidney to be loose and very movable and the stomach dilated, extending from the normal limit above to several inches below the level of the umbilicus, with tardy expulsion of the contents The liver area was somewhat smaller than normal, but the other organs presented nothing abnormal Analysis of the stomach contents after a test breakfast, showed a total acidity of only 24, and an entire absence of free HCl Rennet test, no result in twelve hours Indican in excess in urine My first prescription contained in each fluid dram 10 m of dilute HCl with 15 m of glycerole of pepsin, 1¼ m of Tr Nuc Vom and ½ m of carbolic acid A teaspoonful was added to half a glass of water and beginning half an hour after meals the patient sipped the entire solution during the hour following Shortly after beginning treatment she was attacked with a severe diarrhea, which necessitated a different line of medication for a week or more Then a new digestive mixture was given with the dose of HCl reduced one half, and the other ingredients except pepsin omitted

February 25, 1897, the patient came on from New York and reported improvement in nearly all ways She had continued her last mixture The stomach analysis now showed T A 40, and free HCl 0146 Less fermentation and better sleep No excess of indican in urine The pepsin was now left out of the HCl mixture and a few drops of carbolic acid were again added to it Massage of the abdomen was tried but proved too exciting to the menstrual function, the first treatment having brought on the flow out of time and in excess Since the above date the patient has seen me at long intervals only October 7, 1897, she came on to Philadelphia and reported that she had continued the HCl mixture until six weeks previously, and considered herself then practically well She had gained 12 pounds in weight, presented a good color and clean tongue, and had lost most of her symptoms except the constipation She afterward fell ill with grippe in New York and came under the care of Dr Lockwood in that city, on account of this disease and its complications She was confined to her bed or her room there a large part of the winter, but at the end of it all her physician wrote me under date of March 28, 1898, that a gastric analysis showed total acidity 50, free HCl 22 (equal to 080) and combined HCl 22 She reported herself to me again April 4, 1898, and looked well considering her recent long illness There was improved gastric motility, but her stomach was still greatly enlarged, she having declined intragastric electricity and abdominal massage, the two surest remedies for that condition

Case 2 —Lady, aged 40, wife of a physician in a neighboring city, consulted me March 22, 1897, on account of paroxysmal attacks of indigestion, from which she had suffered for twenty six years They were characterized by violent eructations of gas, and seemed to be caused by some unusual emotion or excitement Formerly they occurred once in several months, and were not followed by any specially unpleasant consequences except nausea and some feeling of oppression But within the last two years there have been three serious attacks of the kind, which were followed by colicky pains and jaundice, with pruritis lasting a week These attacks also followed some marked nervous shock or emotional excitement One occurred just after her father's death Between times she is said to have had usually fair digestion, with no pain or discomfort after meals and very little eructation Her bowels have been fairly regular as a rule, but she is very constipated always at the time of the attacks The latter of late, have sometimes recurred every day for several weeks, accompanied by severe colicky pain and vomiting Ingesta taken two or three days before have occasionally been vomited Color pale and looks dejected Physical examination Lungs and heart normal Liver enlarged Stomach, slight displacement downward along with atonic dilatation The upper boundary was one to one and a half inches too low, and the lower boundary between two and three inches below the level of the umbilicus The kidneys not palpable No tumor Gastric analysis after test breakfast T A 12, free HCl entirely wanting Small amount of mucus Diagnosis Chronic catarrh of the stomach and duodenum Prescribed ℞ Tr Nuc Vom flʒii, Ac hydrochlor Dil qs ad flʒi Sig 10 to 15 drops in half glass of water after meals Diet to be as nonfermentable as possible Two months later patient reported improvement No further attacks August 6 of the same year her husband reported that she had been obliged to continue the mixture regularly Every attempt to omit it was followed by a return of indigestion October 14 Patient recovered a few days ago from one of her severe attacks, which lasted two weeks with eructation, pain and constipation Gastric analysis T A 18, free HCl none, mucus very small amount Prescribed ℞ Ac hydrochlor dil flʒvi, glycerol pepsin qs ad flʒii Sig —Ten drops in half a glass of water half an hour after meals by sips Every other week to take the following ℞ Argent nitrat gr x, Ext taraxaci ʒi M et ft pil No lx Sig —One after each meal April 21, 1898 Has taken both medicines as above ordered—the HCl mixture continuously and the silver half the time She now has a good color and is very much stronger No further attacks Gastric analysis T A 40, free HCl 041, mucus a small amount The lower border of the stomach was found to be near the level of the umbilicus

Case 3 —Lady, a teacher, aged 25, referred by Dr Samuel Bolton of Philadelphia, October 6 1897 Her chief complaint was headaches and vomiting every few days, with much nausea and occasional vomiting, especially evenings, between the attacks There was also stubborn constipation and feeling of load in her stomach after meals Organs generally found healthy except stomach, which was moderately dilated, extending down to half an inch below the umbilicus, with delayed emptying The gastric analysis showed only a very small amount of free HCl (014) though the T A was 66, representing largely fermentation products There was much mucus in the stomach I advised lavage and the combination of HCl and pepsin as the main treatment On account of marked starch indigestion, she also took Taka Diastase for a time, and Roncegno Water was taken for some weeks to bring up the quality of the blood

On April 9, 1898, I found the stomach much retracted in size, the lower border being one and a half inches above the umbilicus, and the gastric analysis showed T A 56, free HCl 075, mucus a very small amount She had had no severe headaches with vomiting for three months, and had regained a normal color, though her gastric catarrh is not yet entirely well

Case 4 —Gentleman, aged 66, consulted me July 21, 1897, in Atlantic City on account of chronic indigestion, from which he claimed to have suffered nearly all his life Painful accumulations of gas and obstinate constipation were prominent features The external physical examination revealed nothing abnormal Gastric analysis T A 16, free HCl wanting Starch digestion good Mucus very small amount He was placed upon HCl and pepsin in the usual way He has since seen me several times on account of his wife, but reported that he himself was doing so well on the digestive mixture as not to require any further medical assistance

December 16, he was seen and was then feeling well On April 22, 1898, his wife called to consult me for herself and reported that her husband had been continuing his HCl and pepsin, though less regularly, having virtually recovered his health He had taken no other medicine except a little nux vomica during the first few weeks and a laxative at night He had not had massage except such kneading over the abdomen as he had been able to give himself

In this case no opportunity has been offered of testing the stomach contents again, but it is highly probable, from the decided improvement in the patient's digestion as well as in his general health, that the gastric glands are now doing much better work

Reports of a number of other cases might be added in which under a treatment consisting either entirely or mainly of the administration of HCl and pepsin, conditions of apepsia or hypopepsia improved more or less markedly, the gastric secretion having returned to the normal Without claiming that such fragments of clinical experience can be accepted as demonstrating beyond question that HCl stimulates the gastric glands, it must be admitted that a strong presumption is thus established as to the existence of such an action

RECENT THERAPEUTIC APPLICATION OF THE VALERIANATES OF CREOSOTE AND GUAIACOL

Presented to the Section on Materia Medica Therapeutic and Pharmacy at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY J W WAINWRIGHT, M D

NEW YORK CITY

It can be safely assumed that the marvelous evidences of progress which the world has witnessed during the last quarter of a century in the science of medicine, especially in the department of clinical medicine and surgery, in very great measure may be justly attributed to the discovery of the relationship which exists either directly or indirectly between certain diseases and a comparatively small group of micro organisms which are now known to be pathogenic Out of this application of bacteriology or microscopic botany to the practice of medicine has been developed our present aseptic and antiseptic methods of wound treatment and also our therapeutics of many infectious diseases The knowledge that we now have of the causes of infection in wounds we owe to the genius of Lister, who has taught us also how we may securely guard against suppuration and other germ-induced pathologic conditions Similarly Pasteur Koch, Klebs and others have not only enlarged our sphere of information as to the nature of many diseases to which mankind is liable, but have also clearly indicated the only means of preventing their future progress by isolation and disinfection

Sepsis therefore occupies an important position in the mind of the clinician, and in consequence, imperative demand has arisen for a class of remedies known as antiseptic agents on account of their ability to counteract the pernicious activity of pathogenic micro-organisms The chemists have been diligent in their investigations and have placed in the hands of the therapeutist powerful weapons to be used in the warfare between the human body and the invading hosts of disease breeding cocci and bacteria

We must not fail to recognize and fully acknowledge the important rôle played by the white blood corpuscles in protecting the human organism from infection, without such natural antiseptics the human race would have disappeared many centuries ago The aim of therapeutics in this class of diseases is to aid in the battle between the leucocytes and the germs by increasing the functional activity of the former and weakening the virulency of the latter It is also important to acknowledge the indispensable aid to be derived from hygienic measures in this direction, and especially the great value of sunlight pure air, and wholesome, easily assimilated food, all of which, from this standpoint, may be regarded as accessory antiseptic agents

Many of the chemic antiseptics are poisonous to all forms of life, and when these agents are used in medicine it is necessary that we be careful that in our efforts to destroy the bacteria, we do not inflict permanent injury to the patient One of the most remarkable of our antiseptic remedies and at the same time perhaps, the least poisonous to the human system, is beechwood creosote, which has had an established place in medicine for more than half a century, but as you are aware, creosote has been largely adulterated in the shops and impure carbolic acid substituted, and thus the best results were not at first secured As a result of Sommerbrodt's efforts on behalf of creosote from beechwood, however, it received greater consideration in the treatment of phthisis, and this interest resulted in our obtaining it finally in a pure state Creosote being a compound of various elements, chiefly guaiacol and creosol it was thought by some that more favorable results might be obtained from the principal ingredient guaiacol, and this was isolated and used with results known to all In these remedies we found prompt antiseptic and germicidal properties with less poisonous effects upon human beings than from the common phenol or carbolic acid, which in the early day of Listerism was the most prominent among our antiseptic agents Guaiacol has also become widely known through its remarkable power of reducing temperature when applied to the surface of the body, which discovery is due to Sciolla

This brings us to the consideration of the newer of the many derivations or compounds of creosote the valerianates of creosote and guaiacol for brevity denominated eosot and geosot They are nearly neutral esters, having an odor resembling somewhat that of the English walnut, and boiling under normal atmospheric pressure at about 260 degrees C, are soluble in alcohol, ether and benzine They are administered internally in coated gelatin capsules, each containing $3\frac{1}{3}$ min and in liquid form either diluted with absolute alcohol and flavored with oil of peppermint, cinnamon or cloves or directly in milk The dose is from $3\frac{1}{3}$ to 9 min three times a day

A convenient formula is as follows

℞ Eosot or geosot, 20 ccm (fl dr v)
Alcohol 95 per cent , 80 ccm (fl oz ii dr v)
Ol menth pip , 0 6 ccm (gtt x)

M. Each tablespoonful contains about 12 min of eosot or geosot Mix dr i to dr iii with plenty of milk and give this dose in three equal parts daily

It is generally conceded that in the treatment of phthisis, for a decade at least, creosote or its derivatives have given the best results of any of the multitude of remedies lauded, but creosote has been so destructive to the digestive and alimentary functions that but seldom a patient would be found who could continue its use sufficiently long or in large enough doses to produce a lasting or permanent effect The poor patient would lose his appetite and desire for food and consequently his physical strength and power to battle with the disease Besides this, there was ever present the depressing and self-conscious factor of his own limitations toward ultimate recovery increased by the never-ceasing gastric distress

The valerianates seem to meet all the requirements as remedies destructive to this disease without untoward effects They increase the appetite and weight, relieve cough, hectic and night sweats The valerianic acid component, by its sedative action on the nerve centers, particularly the sympathetic, enables the patient to enjoy quiet and refreshing sleep as well as a sense of ease and comfort not secured by other remedies Being eliminated largely by the mucous membrane their bacteriologic effects are quickly apparent when used internally in bronchitis, acute gastritis, chronic gastrectasia, typhoid fever, and intestinal irritation, when used externally in lupus and all purulent inflammations, as well as subcutaneously in glandular enlargements of tubercular origin, in hip joint and other bone complications, and as a spray in all nose and throat affections

Physiologic action—Providing the amount of acidity of the secretions be sufficient to replace that of the acid in the combinations, the valerianates of creosote and guaiacol would be decomposed in the stomach The hydrochloric acid of the gastric secretion varies greatly in different people as well as in the same patient from day to day and as the estimate is made before or after meals There is also a great variation of acidity in consequence of the character of the diet as well as at different periods of the day All these conditions must be considered in determining to what extent a combination will be separated into its several constituents in the stomach, hydrochloric, being the stronger of the acids, would under certain conditions replace the valerianic acid or have the effect of decomposing the combination of the valerinate, thus releasing the creosote or guaiacol in the stomach, but such a degree of acidity would very rarely occur, and without an abnormally large amount of hydrochloric acid one would not find the decomposition take place there, but that the remedy would pass on into the intestines and upon encountering the acid antagonist, alkalinity, would then and there be resolved into the two constituents, guaiacol or creasote and valerianic acid This would be the usual method, but it might occur that the alkalinity of the intestinal secretions would not be of sufficient degree to decompose a compound, especially if the remedy were of a character to resist its action This would occur to a greater or less extent with a combination whose constituents were chemically firmly fixed The more stable the combination the more surely would a greater or less amount escape in the feces unchanged It is not at all probable that this decomposition is brought about by the ferments or the products of fermentation, as has been claimed necessary for the decomposition of the carbonates of creosote and guaiacol, but that the remedies would act largely in the alimentary tract as they do in the test tube, due allowance being made for slight variations not likely to be material If the liberation of the several components depended upon the products of fermentation alone, or even to a quite considerable extent, we would not be able to secure the germicidal effects of the creosote or guaiacol in organs or tissue remote from the intestinal tract as in phthisis, for the creosote or guaiacol having once rendered the intestinal tract aseptic it would remain so for a considerable time, and if the remedy were continued it must necessarily pass on through unchanged, not encountering the products of fermentation necessary to decompose it

This theory can not be reasonably assumed, for clinically we know that the creosote or guaiacol can be pushed to such an extent as to completely saturate the organism It has been claimed that the extreme volatility of the valerianates admits of their absorption directly into the circulation as the valerianates, and without the necessity of a chemic action, that they are separated into their component parts after entering the circulation by the alkalin constituents of the blood, as is evidenced by the odor of creosote or guaiacol so quickly appearing upon the handkerchiefs of those using them for coryza This property is of great advantage, as it is apparent that the patient would thus be quickly under their influence without the necessity of chemic changes in the intestinal tract to prepare them for absorption by a decomposition necessary in the more stable compounds such as salol, resorcin, the carbonates, etc To this property may be attributed the small doses necessary when compared with other remedies, as the whole of the valerianates is utilized

As regards the rationale of the action of guaiacol,[1] it has been found that "the beneficial effect of guaiacol in tuberculosis is chiefly due, not to any direct action upon the digestive organs or the blood, but to its combination in the blood with the albuminous bodies (toxalbumins) derived from the growth of the bacilli, that the absorbed guaiacol combines with these products and renders them harmless, and that they are further changed by oxidation, the guaiacol being liberated as a salt of ethyl sulphuric acid, and the other decomposition products being eliminated in the urine The products of the bacilli bring about the fever sweating, disordered digestion, etc, and with their destruction the ill effects pass away" This appears a very probable explanation and it is evident that an organic compound such as the ester of valerianic acid, which is quickly and easily decomposed, yielding nascent guaiacol in a condition ready for immediate absorption into the blood-vessels, is the most efficient and economical method of administering this invaluable remedy It would also seem that this is the best form in which to give guaiacol in the treatment of typhoid fever and other intestinal disorders

---

[1] Berliner Klinische Wochenschrift, Jan 18 1892

The clinical results obtained with the valerianates of creosote and guaiacol may be summarized as follows

Dr Rieck, Bassum, Germany, has an article in the August number of the *Medizinal Zeitung* of Berlin, August, 1897, on the valerianate of guaiacol in the treatment of tuberculosis which shows the following results Of seventy six cases treated in the various stages and forms of tuberculosis, he reports thirty-one cures, and thirty-two of the remainder so much improved as to have almost reached complete recovery, nineteen of the thirty-two giving up all treatment because they felt perfectly well There were eight fatal cases in the whole number treated, rapid and extensive destruction of the lung three, cerebral tuberculosis two, and general tuberculosis three The Doctor says that during his whole experience he has never been able to obtain results which even approximated those treated with the valerianate of guaiacol (geosot), not only in tuberculosis but in bronchitis, especially of children, in broncho-pneumonia, catarrh of the bronchi, larynx, pharynx and nasal passages in acute gastric catarrh and in bone tuberculosis by injection directly into the bone tissue, and finally in lupus In the cases of catarrh of the apex treated, twenty four in all, there was quick and permanent relief, night sweats disappeared, sensitiveness to atmospheric changes lessened, weight and appetite increased and the cough was reduced to an occasional evacuation of mucus which soon became less tenacious and was easily ejected It acts pre eminently upon the mucous membranes and is therefore useful in diseases of the stomach, intestines and the respiratory passages It is especially a remedy for tuberculosis, producing no irritation whatever, but in a few days bringing a feeling of comfort and ease

Dr W Zinn of the "Second Medical Clinic University of Berlin," known as Professor Gerhardt's Clinic, published in *Therapeutische Monatschefte*, Berlin, 1898, a communication entitled "Further Results with the Valerianate of Creosote (eosot)," in which he states that "Dr Grawitz reported in the *Therapeutische Monatschefte*, Berlin, July, 1896, thirty five cases of tuberculosis treated with the valerianate of creosote (eosot) as well as a number of stomach and intestinal disturbances, stating that the remedy was taken in all cases without ill effects to the digestive functions I have now to report that since the publication of Dr Grawitz's article we have treated eighty more cases of tuberculosis with the valerianate of creosote As a rule, the remedy was given in capsules, each containing 3¼ min, one or more capsules three times a day In several cases the medicament was continued for several months It was used in all forms of tuberculosis and it was especially noted that there was in no case disturbance of the gastro intestinal canal It is accepted that of all the many remedies which have been recommended for tuberculosis the beech wood creosote alone retains a prominent place notwithstanding its use has so often been productive of disagreeable effects The valerianate of creosote is therefore worthy of especial mention because of its freedom from these disturbing influences Particularly in the early stages of tuberculosis the eosot will be found of great service Finally, according to the experience had with the eosot in the Gerhardt Clinic, we can say that it fulfils all the requirements of a reliable preparation which can be taken and well borne for long periods"

Dr Frank Woodbury of Philadelphia in a paper read before this Association at its meeting in Philadelphia last year reports having used the valerianate of guaiacol in full strength and diluted with liquid albolene as an anesthetic in nasal operations as a substitute for cocain, and found it to possess decided anesthetic effects slower in appearing than from cocain and not followed by secondary hyperemia The antiseptic power is also of great value in throat and nose operation In painful affections of the skin attended by hyperemia the guaiacol valerianate relieved pain and checked further pus formation Small compresses wet with the guiacol valerianate applied over the painful spot afforded almost immediate relief in neuralgias Dr Woodbury "also found the valerianate highly useful in erysipelatous conditions, in rhus poisoning, in acute and chronic rhinitis, in all inflammatory conditions associated with or producing fermentation, when administered internally"

In Langsdale's *Lancet* for March 1898 I find a report of three cases of phthisis by Dr C F Wainright, Professor of Clinical Medicine, University Medical College, Kansas City, Mo I quote Dr Wainright "In each case treated, tubercle bacilli were detected in the sputum" I venture to make a brief abstract of these clinical reports

Case 1—Man, 32 years of age With tubercular antecedents The disease of lung was of two years duration and attended with usual symptoms fever, chills loss of flesh night sweats cough, etc Upper portion of right lung consolidated and left upper lobe partially Five drops of geosot (valerianate of guaiacol) was given every four hours and continued with very little cessation for five months The patient at last report had resumed his daily occupation, was coughing very little, temperature had been normal for a month or six weeks, he had gained ten pounds in flesh, the consolidation had gradually lessened and he was apparently on the way to complete recovery No other medicines had been used in this case

Case 2—A man in first stage of acute tuberculosis Had been sick only five or six weeks The lower lobe of left lung was consolidated and there were also signs of pleurisy The usual symptoms were manifested loss of flesh, night sweats anemia, indigestion, diarrhea cough, and sometimes bloody expectoration Eosot was given commencing with two drop doses, gradually increased to eight drops four times daily in milk This was continued three months and the patient gradually improved but had not yet fully recovered

Dr Wainright "believes that this man's life was saved by the remedy, as from all appearances he would have died in a few weeks had not the eosot been given"

Case 3—A young lady 16 years of age, mother dead of tuberculosis, had two or three years previously suffered with tuberculosis of the shaft of the tibia requiring surgical treatment She developed a tuberculous process of the left apex which in four or five weeks had consolidated the entire upper lobe Guaiacol, creosote oil of cloves and other remedies were tried and had to be abandoned on account of great irritability of the stomach She was then given the eosot (valerianate of creosote) in capsules, and after four weeks when the fever had subsided, she removed to New Mexico and by the influence of climate together with the eosot which she has taken constantly she is now doing well

Dr Wainright concludes "I have reported these cases, they being typical of many cases I have been treating Am using these preparations extensively in other cases and have had uniformly good results"

The valerianates are being used at the Loomis Sanatorium for Consumptives Liberty N Y Dr Stubbert, the physician in charge in an article published in the *New York Medical Journal* April 2, 1898 says that "geosot, valerianate of guaiacol, proved an agreeable form of administering guaiacol It was found less irritating to the stomach than creosote " I have very little time to refer to other valuable uses of eosot and geosot, such as their value in overcoming irritability of the stomach as in cases reported by Dr W E Anthony of Providence, R I, where in the nausea of early pregnancy and the sick stomach of Bright's disease of the kidneys they gave prompt relief Having indicated some of the applications of the valerianates of creosote and guaiacol in clinical medicine and surgery, with one further reference I will close Surgically Dr Rieck refers to two cases of lupus of the face cured by applications of geosot and also to two cases of tuberculosis or white swelling of the knee and hip joint cured by injections of geosot into the capsule of the joint Dr Rieck also positively states that the valerianate of guaiacol cures bone tuberculosis, though not through the usual channels of absorption but by direct local application and declares that there is no question but that the use of the valerianate of guaiacol will permit of a marked extension of conservative measures in the treatment of tuberculosis of the bones and joints

---

THE GENERAL PRINCIPLES OF ALKALOIDAL MEDICATION

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10 1898

BY W C ABBOTT, M D

CHICAGO

My purpose in coming before you is to present some of the general principles governing that form of medicinal treatment which I have denominated "Alkaloidal Medication," and I trust that I may be enabled to present them with sufficient force and clearness to make my meaning distinctly understood I am prompted to this effort by the belief that by bringing the subject before this Section of the great Association, we may correct some mistakes which my experience shows to exist very generally among the members of our profession

There is an erroneous idea abroad that those who favor alkaloidal or dosimetric medication aim to establish a distinct system of practice This is a great mistake, and a careful perusal of the literature of the subject will show that the word "system" is used by its opponents while the word "method" is used by its friends In other words, what we claim for alkaloidal medication is that it is simply an up-to date method for the treatment of disease, whereby departures from physiologic equilibrium can be controlled more quickly, safely and pleasantly than by any other known method This claim we base upon the fact that alkaloidal therapy is founded upon the use of remedial agents in a state of chemic purity, completely prepared outside the body for ready absorption, leaving practically no chemistry at all to be performed by the ailing and weakened cells

The agents we utilize are the active principles of plants—alkaloids, resinoids, glucosides and concentrations—and certain mineral preparations, all in a state of chemic purity In fact, we use the same remedies we always did, but with the "dirt left out " For convenience in dispensing, these agents are usually given in the form of granules or minute tablets, accurately divided and measured to minimum dosage, to be given at frequent intervals until effect By this means one is always absolutely safe, utilizing the smallest possible quantity of the best obtainable means to produce the desired therapeutic result How to obtain this result most speedily, safely and pleasantly should be the study of every practician of our art The use of these "arms of precision," in cumulative minimum doses, gives us such perfect control of the physiologic disturbance at the beginning of an acute disease that we promptly restore the normal equilibrium, jugulate the attack, and cure the patient before serious organic lesions have been produced This effect may be secured in all cases depending upon a controllable congestion, such as bronchitis, pneumonia, peritonitis and kindred conditions Eruptive fevers will pass through their cycle under any form of treatment, but when treated alkalometrically they do so in a mild and greatly modified form, while that class of affections of which typhoid fever may be taken as a type, may either be aborted in the early stages or, if seen too late for that, may be conducted through the regular course to a quick and safe termination, like the eruptive fevers The early control of the congestive element means much as to the subsequent course of any febrile attack, whether it be that of a specific fever or of a local inflammation

In the practice of alkaloidal therapy certain customs or basal principles have been developed, which, though not confined to this therapeutic method alone, have become, in a manner, habitual to its followers Whether or not these principles are well-founded you may easily determine I will first mention the giving of small doses, frequently repeated, until the desired effect is produced, that is, every fifteen to thirty minutes, according to the severity of the attack, until some improvement is manifest Such doses should then be given, at greater intervals, as will keep up this effect By adhering closely to this method it is simply impossible to overdose the patient In this way the alkaloids and other active principles and the most powerful mineral drugs may be used with perfect safety Here we have the first illustration of the value of the alkaloids in promoting accuracy of medication These agents are clean-cut and well defined in their effects and totally devoid of the uncertainty which hangs over the galenicals For instance, when we give pilocarpin we direct the dose to be given every fifteen minutes until sweating occurs We *know* this will be the effect, and no one who has enough intelligence to be left in charge of a patient can possibly mistake so simple a direction But if we were to give the fluid extract of jarborandi we could not know whether it would induce perspiration or dry it up, because the way it will act depends on which of its alkaloids—pilocarpin or jaborin—happens to be in excess Consequently we have to go into a long explanation to the nurse, which she is not likely to comprehend, because we do not really know just what effect the medicine is going to exert

I will not occupy your time in detailing more of such illustrations, but will merely ask you to call to mind the great number of drugs that contain more than one active principle, some of which are antagonistic to the others, as in digitalis, ergot, hyoscyamus, opium, etc Observations made in India upon the treatment of dysentery with ipecacuanha deprived of its emetin render it probable that many plants now thought to possess but one useful active principle may contain others of no less value When applied to the treatment of acute diseases, the alkaloidal method directs that active medication be instituted the moment congestion is detected, before sufficient organic lesion occurs to make a specific diagnosis possible, or in other words, it directs that we apply to acute diseases, acute or active treatment, reserving the slow or expectant sort for chronic conditions There is no such thing in rational therapy as a fixed dose Under the old methods the dose is modified by sex, age, weight, strength, habit, time, season, general condition and idiosyncrasy—each considered apart from the effect of the disease—therefore, in no instance can the dose be more than roughly approximated to the probable need The principles governing alkaloidal therapy do away with all this The initial dose is made too small to do harm under any circumstances, it is given in a shape that allows it to be dissolved and absorbed almost as quickly as if given hypodermically, and it is repeated at short intervals until the desired effect has been obtained

Here is where individual differences arising from the personal equation are equalized, one will require but two or three doses while another will require ten or twelve to produce the same effect And it is not impossible that the constant impression of small doses frequently repeated has the same power of controlling acute disease processes (a power apparently so completely out of proportion to the amount of the agent used) that a film of oil has in preventing the development of waves in an ocean storm This delicate, scientific handling of a therapeutic agent, especially in the beginning of disease processes, has its uses, but by no means does it preclude the employment of good, strong, Anglo Saxon, Dewey blows when they are indicated There is need of and room for both in the practice of medicine The researches of Bouchard and the clinical observations of thousands of physicians have demonstrated the importance of a clean alimentary canal, and also the large part played by intestinal sepsis and autotoxemia in the semeiology of most diseases Accordingly the employment of a saline laxative—preferably a chemically pure magnesium sulphate in effervescent combination—to empty the bowels, and of intestinal antiseptics to prevent microbic action, are inculcated as essential features of the alkaloidal treatment of any disease By these means the body sewers are flushed accumulations of toxin breeding debris are removed or prevented, and the kidneys are relieved from that overwork which, resulting in an irritation, constitutes such a serious menace to the organ, being liable to result in actual and perhaps fatal nephritis

One of the singular anomalies in medical belief is the persistence of the idea that the alkaloids are dangerous as compared with the galenic preparations from the same plants But little investigation is necessary to demonstrate the fallacy of this idea Infusions, tinctures, decoctions and extracts depend for their therapeutic efficacy upon the active principles which they contain, and, in view of the fact that no two crops of the same plant ever contain the same percentage of active principles, they must be present in these preparations in unknown and varying proportions Not only does the amount of active principle in any plant vary with the seasons, but it also varies with the localities in which it grows and the conditions under which it is cured and kept Therefore as usually prepared, each new lot of extract or tincture must be tested chemically or at the bedside before the physician can tell how much he should give Even the dose of today may not be that of next week, for the drug may deteriorate or, in case of insecurely corked alcoholic or ethereal preparations, may gain in strength through the evaporation of the menstrum No one can reasonably claim that uncertainty of strength adds to the safety of a dose, nor that the presence of inert matter renders it less dangerous Besides, as in the case of digitalis, some of the ingredients of a tincture or extract may hinder the absorption of the desired remedial agent, and the most valuable period for medication may thus be lost

While the old methods deal with uncertainty, the alkaloidal deals with certainty while the old asks the sick cells to do both chemistry and absorption—when the former can be at best but poorly performed—the new calls for absorption only Thus a more accurate and scientific therapy is made possible It is strange that the laity are quicker to recognize the merits of alkaloidal medication than are the majority of physicians It does not take the patient or his friends long to appreciate the wonderful potency and efficacy of the granules of the active principles, and yet many of the medical profession still fail to comprehend Occasionally one becomes imbued with the spirit of alkaloidal medication, and, astonished at the excellent results obtained, becomes inspired with a new enthusiasm and awakes to the fact that with these tools he can do better work than he has ever been able to do before No less an authority than Prof Shaller says in his "Guide to Alkaloidal Medication" "The writer has had years of experience in prescription writing, and also in dosimetry—alkaloidal medication—and he has no hesitancy in saying that his results with the alkaloidal granules have far surpassed what he was able to accomplish while using the cruder preparations of the same drugs"

Accuracy in prescription requires a corresponding accuracy in diagnosis The name of the disease is not enough There must be a distinct conception of the pathologic condition of the organs and the cells and tissues composing them We must have a clear idea of the nature of the disease and of the treatment required, and administer those remedies which are indicated by the morbid symptoms The time has come when we should discard the old shotgun prescriptions with which, through the association of a number of substances, the practitioner hoped to at least hit the mark with one of them The active principles are "arms of precision" and bear the same relation to the old fashioned galenical preparations that the rifle bears to the shotgun

The standard works on practice have little or nothing to say of vasomotor spasm and paresis, yet these are among the conditions most frequently demanding the active interference of the therapeutist Much might be said in elaboration of this subject the importance of which we are but just beginning to realize but it must suffice to say that such clear cut control is just as impossible under the old methods as it is possible and easy under the alkaloidal Alkaloidal therapy teaches that the treatment must proceed as rapidly as the disease The more acute the disease the more frequent the repetition of the dose This statement is almost axiomatic but it has been reserved for the alkalometrist to recognize it and call the attention of the profession to its importance

Although I have already referred to the jugulation of acute disease, the prime imp [illegible] of the prin ple involved warrants a further word. I can not too strongly emphasize the importance of instituting a strong, active treatment, directed to the dissipation of the prominent symptoms, at the earliest possible moment of attack, and before the danger has definitely located itself. Otherwise we may be too late, and cerebral thoracic, or abdominal symptoms may appear, the disease having the form of a fully developed meningitis, carditis, pneumonia, or gastro enteritis, any one of which must be allowed to go through all its stages unless the patient should succumb before the end. The use of the little granules has led casual observers to ask if alkalometry does not savor of homeopathy. Were it not that the question has been asked by those who ought to know better, I would not occupy your time with this matter but a few words are enough. The original idea of Hahnemann was that a remedy should be selected whose gross effects coincided with the symptoms shown by the case, and that if properly selected, a single dose would suffice for a cure. The use of the infintesimals was a later development. It was necessitated, in order to hold his followers, by the impossibility of rendering the theory universally applicable when tangible doses were administered. This was one of the earlier applications of the art of hypnotism, and the influence of his "suggestion" obtains to this day. In alkalometry the remedy is chosen that most nearly antagonizes the disease condition present, and is given in small but effective doses until the drug effect has been raised to the point where it exactly counteracts the disease-effect, a reaction to the normal is the result. An apparent application of similia may be seen in the alkalometric practice of giving such stimulants as strychnin arseniate and sanguinarin in acute diseases of the parts over which these drugs have a selective influence, but the reason for this is, that there is an antipathic effect to be secured. Disease means a lowering of vitality either functional or organic. If the vitality of the pharyngeal tissues be normal, pharyngitis will not occur. It does occur, consequently the resisting power of the pharyngeal tissues is below normal. Our grandmothers recognized this and treated pharyngitis very successfully with capsicum tea, we, more pleasantly, treat it with strychnin, sanguinarin etc., or with strong local astringents. This is clearly "antipathic" and not "homeopathic."

The principle of administering a remedy until the desired effect has been secured simple as it appears, was never satisfactorily applied, or even understood, until the present method was advocated by Burggraeve. This principle is of especial importance in the treatment of children, to whom the giving of anodynes, narcotics or antispasmodics is often a necessary but dangerous measure. No drug, however powerful, need be excluded from child-practice when employed alkalometrically; everything depends upon the accuracy of meeting the indication, and upon the gradation of the dose, all danger is removed by cumulative minimal dosage.

To the superior control which the physician exerts over his drug, to the promptness and certainty of his medication, and to the avoidance of all the ills resulting from the intermediation of the pharmacist, conditions easily possible to alkaloidal therapy, I can but casually refer. The superior facilities for treating emergencies which the physician who carries his granule case possesses over him who has only a lead pencil and a bit of paper, the difference in favor of carrying an ounce of active principle instead of eight pounds of galenical powder (to him who has to carry them), and many other practical points, must be left to you who know them as well as I. When the pathologic conditions that are present in every attack of disease are clearly comprehended, and when the effect of each medicament upon these conditions has been definitely determined, then, and not till then, will therapeutics be established upon a firm basis, and the practice of medicine become a true science. But this happy condition can never be reached until the members of our profession turn to the use of remedies distinct and uniform in their effect. And as alkalometry makes for keener study of disease states, greater accuracy in diagnosis and prescription even to certainty as to the dispensing of medicines, it is bound to win in the contest with the old, careless, slovenly, half-hearted, pessimistic methods.

HOW FAR DOES A SCIENTIFC THERAPY DEPEND UPON THE MATERIA MEDICA IN THE CURE OF DISEASE?

Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY ELMER LEE, A.M., M.D., PH.D.
NEW YORK

A large part of medical student life is spent in trying to memorize the contents of the materia medica and its auxiliaries. The drug catalogues sent gratis, and drug circulars and the spurious medical literature for advertising purposes comprise the auxiliaries. Names of drugs are arranged into classes for convenience, and later the names begin to keep company with other names which stand for disease. The hapless student works away for some years till he is prepared to answer examination questions pertaining to diseases and the drugs which it is affirmed cure them, he is then ready to be graduated in medicine, and soon takes up the practice of this acquired information upon other hapless ones, perchance to be found in some eleemosynary institution to which he is assigned for having shown himself specially fitted or judged by his ability to pass a medical examination in current theory and practice.

The ambition of the student is worthy of a better fate than the disappointment which is certain to settle upon him in the battle against disease. He hopes to succeed where others fail, for he does not yet suspect where the real weakness of his therapeutic system lies, believing that failure to cure depends only upon an imperfect individual knowledge of pharmaceuticals and their exact application. Such is the feeling at the inception of the medical career, but later on in the practice of medicine it is realized that the anticipation of a perfect understanding and the possibility of curing where others fail, was a dream.

Schools of medicine rise and fall based upon drug therapy, and the widest dissension exists among adherents of diverse medical systems. Claims are set up which alone exist in the brain of the medical reformer. It is impossible to check thought, as well as undesirable, but it is contrary to progress to accept error. It matters not who is the teacher. The materia medica is a vast collection of strange drugs and chemicals, mineral and vegetable, so put together that they form many thousands of pharmacals, for which there is little use in the arts and sciences, and if the truth were to be told, even a less need for them in the treatment of disease The force of habit perpetuates many customs that are fruitless for good, in the same way the favorite prescription continues to dominate therapeutics without a pretense in many cases of either science or reason Man is truly a creature of circumstance, physicians operate in precisely the same way as a rule The homeopathic doctor sticks to the notions of his teachers and the precepts of that system The eclectic physician yields to the influence of similar environmental conditions, imbibing a respect and love for the tenents of specific medication as arranged for him by the clever but erratic wits of some medical classifier who is taken seriously for an authority The great mass of physicians, through an incident of association, make choice of a medical school for study, knowing nothing of its essentials of doctrine perhaps, choosing it rather for the simple reason that its inducements happen to reach them persuasively Seeing then that the selection of a creed in medicine is due to some chance circumstance,,for the student can not possibly choose intelligently—for the best of all reasons, that of not having experience—friendly co operation and not condemnation would be a proper attitude toward those who follow sectarianism in medicine One physician of New York prescribes according to the materia medica on the ground that he knows not what else to do in the treatment of his cases, at the same time admitting freely that his experience teaches the uselessness of the drugs he prescribes A patient was sent from a famous health resort home to die, with a note of explanation of the treatment of the case during the stay in the sanatorium There were copies of nine prescriptions included in the notes on the case to further explain to me how the dying condition of the patient had been reached The doctor there had rained coals of literal fire upon her head The colleague at the sanatorium possesses all the virtues of fine fellowship, but is a physician emphatically detrimental to his patients He is one who stands for a class of practitioners waiting with a pharmaceutic club to crush a symptom of warning and possibly kill the patient at the same blow This is the solemn truth It is everyday experience

In another case a dangerous and extensive colitis had almost accomplished the destruction of a precious life, my counsel was requested at this stage of the case The nurse and family desired me to inspect the medicines, thinking it would aid me The list of prescriptions and proprietary cures which had been used in her case awakened my resentment against the medical teaching that made it possible that doctors could be content to depend upon the materia medica for physiologic reconstruction in the face of such adverse results The patient was made worse by her treatment, even though the mistakes were made by honest, earnest and faithful physicians The patient required a great deal of assistance to re establish her health, but she did not need medicines, either mild or strong

The study of drug therapy may become fascinating, and medical experimentation with human life as exciting as a romance, but these things are not the main object of the true physician Sound health needs for its continuance a regular exercise of the different parts of the body and adequate nutrition for growth and repair When these elemental conditions are not properly and regularly supplied, it leads to disease Then the way to cure is to right that which is wrong, using natural agencies rather than artificial The greatest success in curing the sick is to give scientific attention to such matters as belong strictly to the actual necessities of life forces The materia medica is not required to support vital functions in health and the question is How far is it useful when the body is sick? From time immemorial in the treatment of the sick curative influences have been associated with substances which are not well understood by those who take them Such long existing habits of man in his course of evolution can not be lightly set aside In some future day it is certain that drugs and chemicals will form no part of a scientific therapy This is sure to be the case, for truth is finally certain to prevail From the physical standpoint the materia medica confers no important favor upon either the healthy or sick body, but as yet the mind of the patient will not listen to the divorce between bodily cure and drug effect, though in fact, the drug actually retards health resumption

The principal influence or relation of materia medica to the cure of bodily disease lies in the fact that drugs supply material upon which to rest the mind while other agencies are at work in eliminating disease from the system, and to the drug is frequently given the credit Every physician knows this explanation is in accordance with the facts of the case Experience teaches that to satisfy the mind of the patient, harmless medicines are fully able to be a substitute for the disagreeable and dangerous ones, besides they confer the real or supposed help to nature and never an injury Sugar of milk tablets of various colors and different flavors constitute a materia medica in practice that needs for temporary use only, morphin, codein, cocain, aconite and a laxative to make it complete

If this were not literally true how could the satisfactory cures of the little pill doctors be explained? Their patients are from the most intelligent classes of society, and prefer the harmless doses The effect upon the confidence is the chief element of such slight drug treatment, while the cure is due to the inherent reconstructive forces of nature, aided by the employment of hygienic counsel

The multiplication of new chemicals, which are everywhere pressed upon the physician first, then the public afterward, is pretty conclusive that the therapy of this day is not satisfactory, or else physicians are easily imposed upon by the promises of the impossible from the latest drug claimant It also shows that the doctor is dissatisfied with his standards or loves continual experimentation If a simple natural materia medica prevailed in the profession it would enable the physician to base the cure of disease and his hope for prosperity on selling his wits to the patient rather than the drugs of the apothecary People everywhere ought, and generally will pay a greater price for sound counsel than for a prescription for medicines The strong incentive to excel in medicine is commendable, and should be based upon the desire to be a wise health-counselor, rather than a routine prescriber of chemicals, thus commanding respect and good fees This is proper and just

The drug stores are ready to supply a customer with a drug for his every symptom and for this service they are entitled to commercial profits but if the physician does no more than the druggist, the public estimate between the two will not be [illegible] of the doctor The earnings of the profession average low, and so long as practicing physicians indiscriminately prescribe every sort of chemical that is placed before them, they place themselves in competition with druggists and vendors of patent cures, while the original and independent thinker will always enjoy a greater individuality, and deserves to gather the equivalent in fees in exchange for the higher kind of medical aid in the work of a life-saving profession

10 West 49th Street

THE REGENERATION OF PHARMACY A VITAL NECESSITY OF SCIENTIFIC MEDICINE

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo , June 7 10, 1898

BY OSCAR OLDBERG, PH D (NORTHWESTERN UNIV)
CHICAGO

Medication is indispensable to the healing art The physician without drugs is powerless Indeed, the greater the need of the physician's services, the more urgent is, in most cases, the need of the medicine The purpose of this paper is a plea for the more faithful and effective performance of duty in the preparation and dispensing of medicines If medicine is not of importance in the treatment of disease, then let materia medica and pharmacy be abandoned But if drugs or medicines are really so indispensable that the physician can do little or nothing without them, then it must be one of the highest duties of the physician to give heed to the character of the medicine he employs This truth is apparently to a great extent ignored But it is as important to the welfare of humanity as the science of medicine itself To deny the necessity of faithfulness in the preparation and dispensing of medicine for the sick would be to put the stamp of quackery upon the practice of the physician I am not an alarmist, but it seems to me that any thinking man must, upon due reflection, be led to the conclusion that the condition of therapy and pharmacy is most deplorable and that there is a present and pressing necessity for a radical change Sensational references to adulteration, substitution and other frauds in the manufacture and sale of medicines are as ineffective as they are unwarranted That ignorance and dishonesty are met with in all pursuits is not to be denied It is not my purpose to reiterate such indictments or too add to the proofs of their truth But I assert that the vast progress made in pharmacognosy, chemistry and pharmacy has utterly failed to receive that recognition which compels obedience to its lessons There has not at any other time been a greater disparity between the store of scientific knowledge applicable to the preparation and dispensing of medicines and the actual application of such knowledge for the benefit of humanity Pharmaceutic knowledge is now sufficiently developed to prove more clearly and conclusively than ever before the necessity for the services of the trained expert in pharmaceutic work

We now realize fully the fact that without any reference to intentional fraud and criminal ignorance or negligence, medicinal substances are, from other preventable and unpreventable causes, liable to changes and variations such as render it necessary that they be selected, tested, preserved, examined from time to time, and prepared for use only by properly trained scientific-technical experts who are alone competent to determine their character and condition Whoever dispenses medicines for the sick should know of his own knowledge precisely what he is dispensing and what he is doing He should possess that special education which is necessary to a proper realization of his full duty and its faithful performance Yet medicines are now dispensed by thousands and thousands of persons who possess not the slightest knowledge and training in pharmacy And the most serious feature of this dangerous abuse is the sad fact that a rapidly growing proportion of those who, without adequate knowledge of the risks involved, undertake to provide the medicines required for the sick, are physicians This practice is indefensible except in cases where the physician is so situated that the services of a competent pharmacist are not within reach In such cases the physician can only procure his medicines from reliable pharmacists, preserve these medicines properly and renew his supplies so frequently that the chances of deterioration, dangerous alteration, or destruction are minimized or obviated

If modern pharmaceutic chemistry has taught us anything, it is that medicines do not retain their properties unchanged for an indefinite period, and that the changes liable to occur in medicinal preparations are not limited to a mere gradual decrease of potency They sometimes become nearly or quite inert, and in other cases become so changed as to acquire entirely different medicinal properties We have heard of such bold faced frauds as the manufacture and sale of "tasteless strychnin tablets," put forth to deceive those who do not know that strychnin can not be tasteless We know of proprietary preparations with published formulas which omit to mention very potent actual constituents, but which do name ingredients not contained in the preparations Against these and other similar frauds the physician has an effective remedy, he can get along without them But the practice of dispensing medicines which have not been properly examined, the identity, purity, quality and strength of which are unknown, and the age and condition of which are uncertain, must be regarded as a more dangerous evil because of the many plausible excuses which suggest themselves, and because of the fact that the only effective remedy is not so easily found or applied There are incompetent and dishonest manufacturers of pharmaceutic preparations as well as competent and honest ones There are incompetent and dishonest dispensers as well as competent and honest ones Whatever may be the proportion of ignorant and incompetent persons employed in preparing and dispensing medicines, the physicians have it in their power to do more than any other men to compel a thorough and lasting reform in the ranks of pharmacy The practice of medicine and the practice of pharmacy can not be combined without detriment to both and injury to civilization The higher the standard of medical education the higher must-be the standard of pharmaceutic education also The more a well educated physician knows of pharmaceutic chemistry the more clearly will he see the need of the services of scientifically trained pharmacists who devote their whole attention to the laboratory work demanded by modern medicine, including the preparing and dispensing of medicines for the sick And a well educated pharmacist should not only be competent to perform these services, but will be sure not to encroach upon the duties of the physician

The average drugstore is an altogether unfit place for the proper performance of such important, delicate and responsible duties as those of true pharmacy But instead of dispensing his own medicines the physician should insist upon a radical reform in the average drugstore, including the banishment of the soda fountain, cigar stand and all other excrescences Many druggists are uneducated But the remedy is a reasonable measure of compulsory education which the physicians and the public should insist upon We have numerous schools of pharmacy, and many of them are excellent schools, but not one of the pharmacy laws of the forty States that have such laws requires a single day's attendance at any such school as a prerequisite to the license to practice pharmacy, because the public and the medical profession are so indifferent as not to demand it Reputable and honest merchants, called druggists, wholesale and retail, may buy and sell drugs and chemicals about which they know little or nothing, frequently accepting and furnishing in good faith one thing for another But the only protection against such serious blunders is the faithful application of skill and knowledge by the properly trained pharmacist Druggists, wholesale and retail, may buy and sell drugs which are so old as to be unfit for use, and those who periodically and critically examine their supplies and throw away all medicines not in perfect condition can be only those whose training fits them to do this intelligently The remedy must be the just recognition of the plain fact that the pharmacist is a scientific technical expert who performs special services for which he is entitled to professional fees, and not a mere merchant dependent upon commercial competition

Without rational scientific pharmacy there can be no scientific medicine, for how can the physician learn anything definite about the action of any medicine which is not uniform? Medicinal preparations must not only be carefully and properly prepared from materials of verified identity and quality, and then standardized, but they must be protected against change, examined from time to time, and thrown away whenever they shall be found no longer perfect

The new pharmacy should not be a "store" but an *officine* It should be provided with all the necessary apparatus, reagents, and other facilities for scientific-technical pharmaceutical work, which should include not only the preparation, examination, compounding and dispensing of medicines, but also urine analysis, and other microscopic and chemic examinations required by physicians, the preparation of bacteriologic culture media, etc There should be no patent medicines and other nostrums in the officine of the new pharmacist, no tobacco, no soda fountain, no merchandise—nothing but legitimate medicines, surgical dressings and whatever else is requisite to enable him to perform his proper functions as the laboratory expert and assistant to the physician and the common chemist of the community This is no idle fancy picture of an unattainable ideal It is the reasonable and proper demand of our present civilization Such pharmacies can be maintained in every large city and in numerous smaller cities Not only that, but in places where it may be impracticable to maintain such an officine, divorced from the miscellaneous merchandizing of the average drugstore of today, there can still be a vast improvement made upon the prevailing system

Will not the members of the AMERICAN MEDICAL ASSOCIATION declare in favor of compulsory pharmaceutic education for the practice of pharmacy and for the divorcement of legitimate pharmacy from the commercial drug business, in the interest of the public welfare?

PRESENT STATUS OF SERUM THERAPY

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10 1898

BY GEO W COX, M D

CHICAGO

The history of serum therapy is like the history of a day—a busy day—into which is crowded the memory of a thousand conflicting incidents, all so brief and fleeting in character as to be almost forgotten on the morrow Many of us remember the "good old days" of thumb lancet and fever starvation, when serum therapy was not even a dream, most of us remember when the clouds first began to separate under the influence of scientific research, and all of us remember when the first sunbeam of actual discovery burst upon the world like a meteor's gleam It must not be inferred from this that no hint of the underlying principles of serum therapy was ever scented until the present generation, for a suggestion of them was made nearly two hundred years ago, when the Turks are credited with practicing a crude form of inoculation against smallpox The methods were so imperfect, however, and their success so limited, that the practice was allowed to die out, and many decades passed before Jenner revived the idea and applied it in the form of vaccination Although another half century rolled by before the next great advance was made, it would be very unjust to the immediate followers of Jenner to say that they were content to confine the principles of vaccination to the prevention and treatment of a single disease Many theories were advanced by them—the chief one being the once popular but now almost forgotten isopathic practice of the Germans—and much experimentation indulged in, but their gropings were wholly in the dark until a practical application of serum therapy was made possible by the first important discovery of Louis Pasteur

This great scientist, while still young enough to be addressed as "*mon cher enfant*' by Biot, the discoverer of the phenomena of polarization, taking molecular asymmetry as a cue, had demonstrated the power of the tartrates under certain conditions to deflect polarized light This led him to the immediate study and speedy discovery of the true cause of fermentation—the real beginning of Pasteur's many and varied achievements Then followed in rapid succession the numerous and useful ideas now so familiar to every student of medicine, including the explanation of the cause and nature of infection of contagion and of the principles of prophylaxis and cure by vaccination He also determined the evolution of disease germs, both in and out of the living organism and finally rounded out his brief but fruitful scientific career by giving to the world the new treatment for hydrophobia Thus by Pasteur was laid the foundation upon which the superstructure of serum therapy is now being erected I mention this point in simple justice to the inventive genius of a great man

All great important discoveries through their greatness, soon become so popular in the public mind that their originators are quickly forgotten W[illegible] of the tubercle bacillus, the telephone and the diphtheria antitoxin as commonplace affairs that had been known from the most ancient times, and rarely stop to think of the men who spent years of earnest toil in their discovery and development Richet has truly said that the first course medical student of today is perfectly familiar with many phenomena which the wisest sages of fifty years ago could not understand Lavoisier, Jenner, Galen, Celsus and Hippocrates all knew that fermentations existed and were quite familiar with their consequences, but they had no more conception of their causation than we of the present day have of the origin and proximate character of electric force It was not until the year 1857 that the bacterial origin of fermentation was made known and means devised by which it could be produced, controlled or prevented at will The world of commerce began to be enriched at once, for the wine disease, the beer disease and the silkworm disease each in turn received the attention of the young French physicist, with the result of placing them all under easy control This would seem to be glory enough for one man, and it seems strange that anyone would bid for more, but the highest reward was yet to come in the application of the same theory in regard to the causation of disease in man Pasteur was not a physician, and this makes it all the more remarkable that he should have been singled out by the fortunes of destiny to lead the hosts of medical bondsmen into the light of etiologic, pathologic and therapeutic sunshine Thus, while the whole world acknowledges Pasteur as the "father of bacteriology," as it is known and practiced today, through this relationship he must forever be designated as the *grandfather* of serum therapy The question naturally arises whether the present progeny is of sufficient merit to be considered a worthy offspring of so famous an ancestry

There is a brief, uncertain period in the life of every youth, as well as in every young scientific problem, when the weathercock of prophecy seems to hesitate between the points of great usefulness and utter worthlessness It is the purpose of this paper to show that serum therapy has passed this period of uncertainty and assumed a place among the staples of rational therapeutics It will be noticed that under the general term of serum therapy I include medication by toxins, antitoxins, blood serum and vaccins—all of which are the outgrowth of the germ theory of disease and the direct result of applied bacteriology My definition is, therefore, intended to be practical rather than scientific, and I trust the importance of this phase of the subject will be permitted to outweigh technical inaccuracy In presenting the claims of this new system it is necessary to first point out its great value as a diagnostic agent The incipient stage of some diseases, tuberculosis for example, is so mild and insiduous that its early detection is impossible by the usual methods, but by means of a bacterial product it may be disclosed, both in man and in the lower animals, even before its location in the organism can be definitely determined The advantages of this are self-evident In the human subject it permits appropriate treatment to be instituted before chronicity and complications render the case hopeless, while in the case of cattle it favors isolation or such other disposition of the stock as will insure the owner against pecuniary loss If, therefore, serum therapy had nothing else to recommend it, its value in the early diagnosis of two such diseases as tuberculosis and typhoid fever would insure it a permanent place in the list of esteemed remedies But its worth is not measured by its diagnostic power alone Its well known action as a prophylactic in some diseases is of the greatest moment, while its curative power in others can be accurately described by the one word "specific "

In the consideration of serum therapy in its practical application to the treatment of diseases, it seems both natural and fitting that the one to be mentioned first and with which all comparisons should be made, is that relentless and loathsome enemy of childhood

Diphtheria —To the vast majority of the thinking physicians of today, the mere mention of diphtheria is suggestive of the remedy par excellence in every civilized land—antitoxin To be sure, there is yet to be heard an occasional denial of the most absolutely demonstrated facts in the common affairs of life It is not necessary to burden you with a long list of figures and statistics relative to the grand, onward march of success in the antitoxin treatment of diphtheria The evidence is so overwhelming in its favor, and the few failures and accidents so easily accounted for that but one conclusion is possible to the man whose senses are not wilfully closed to investigation and truth

Tetanus —Early in 1894, Carle and Rattone demonstrated that tetanus was an infectious disease, capable of being transmitted from man to the lower animals by inoculation, but it was reserved for Nicolaier to discover the bacillus of tetanus, a few months after the publication of Carle and Rattone's experiments The bacillus itself, as well as the disease it creates, was extremely difficult to study, and while Brieger made the first important advance in the discovery of tetanin in 1896, it was three years later that Kitasato first obtained the germ in pure cultures and gave to the world the first description of its biologic characters Since that time scientists in all parts of the world have constantly vied with each other in the attempt to find a remedy that would destroy the germ or its ptomains, and thus afford an efficient means of combating the distressing and fatal disease —tetanus Naturally they turned to serum therapy for a realization of their hopes, and with what success their efforts have been crowned may be told in a few words Blood serums are peculiar in their action, and but few of them are perfectly understood Some of them, as the antidiphtheritic serum, exert their influence solely upon the ptomains, making them true antitoxins, while others, like the antistreptococcic serum, perform their work by destroying the germs themselves and thus putting a stop to the production of toxins Others again, such as the antitetanic serum, do not seem to have much, if any, effect upon either germ or toxin, and yet from indisputable clinical evidence they possess an immense therapeutic value Just in what way their good results are brought about has never been determined Professor Roux of the Institut Pasteur has suggested that their action is of a protective character and is directed upon the tissue cells, fortifying them against tetanin, or the still more deadly toxalbumin described by Brieger and Frankel This explanation clearly accounts for the wonderful immunizing properties known to exist in the antitetanic serum, and is the strongest possible appeal for the use of this agent as a preventive Not a single case of tetanus has ever developed after an adequate prophylactic dose of a reliable antitetanic serum was given This fact, demonstrated in hundreds of experimental cases at the Institut Pasteur three years ago, has led to the adoption of a routine practice of immunization by surgeons in places where tetanus is known to be endemic Quite recently a physician told me that he had just used a prophylactic dose of antitetanic serum after a rusty nail puncture, and the results were so satisfactory and his patient so free from apprehension during his illness that he should continue the practice, even if only for its moral effect

The curative properties of antitetanic serum are negatively positive, but not positively negative It cures—or more strictly speaking, it leads to recovery—by preventing any further invasion, but it does not cure the tetanus already existing The only reasonable conclusion, therefore, is that the antitetanic serum should be used frequently at the first suspicion of an attack of tetanus, even before invasion if possible, or at least while the existing poison is not sufficient to cause death While the serum treatment of tetanus is not all that could be wished for, nor all that we expect to see it in the future, as men and methods and means arise for its improvement, yet as we have it today it is by far the most successful treatment at our command In Scotland, where statistics have been most carefully kept, the mortality has been reduced from the former frightful figure to about 35 per cent In the United States during the last two years, according to Dr Frederic S Dennis of New York, who has carefully investigated the subject, the mortality figure is even a shade lower still Five cases of trismus nascentium were reported last year as successfully treated with the serum—cases which previous to the days of antitoxin were almost uniformly fatal

The experiments of Wasserman and Takaki, based upon Prof Ehrlich's theory of the formation of antitoxins, should be remembered for the sake of future investigations in the general system of serum therapy At present, however, they are interesting only from the laboratory standpoint and are absolutely without practical therapeutic value More recently still, considerable local enthusiasm was excited in Rome, where Prof Bacelli's treatment of tetanus with phenic acid was applied in thirty cases with but one death This showing certainly entitles the method to further study, for while such a result in a single series of cases might be purely coincidental, the truly scientific mind should always stand ready to push investigation to its utmost limits when there appears the semblance of a cue The very latest, and what appears to be the most reasonable, theory yet advanced concerning the action of the toxin and antitoxin of tetanus, is that of Roux and Borrel, in which they express the belief that the toxin attacks the nerve centers with such rapacity that the antitoxin, when administered hypodermically, does not reach the seat of destruction in time, or in sufficient quantity, to overcome the evil They reasoned, therefore, that if the antitoxin could be applied directly to the cerebral substance, it might reach the vital point by rapid diffusion and be much more effective In demonstration of this theory they tetanized seventy-nine guinea pigs for their first experiments Forty-five of these received intracerebral injections of small doses of antitoxin and thirty-five of them recovered Seventeen were treated with much larger doses by the hypodermic method, and of these only two survived The remaining seventeen were not treated with antitoxin and they all died So far this method has only been applied in one case in the human subject In this case the operation was entirely successful and the patient made a speedy recovery

Tuberculosis —Quite a number of toxins antitoxins and blood serums have been introduced for the treatment of this disease, and with results that should be regarded as most gratifying, inasmuch as they have not all been absolute failures The original tuberculin of Koch, and the improved product known as "T R", are admittedly most dismal failures as far as curative properties are concerned but in spite of this they have wrought an excellent service in directing and stimulating investigation, as well as being of great value as diagnostic agents Of the newer remedies of this class, as well as of the antitoxins and blood serums directed against the tubercle bacillus and its ptomains, the members of this Section will be fully informed in specially prepared papers relating to this subject It remains, therefore, for me to discuss some of the complications of tuberculosis, and leave the consideration of the tubercle bacillus to the distinguished gentlemen who are making a life study of it and its terrible consequences It has been so often repeated by various competent observers that simple, uncomplicated tuberculosis is easily curable, that it may seem strange to the casual reader that we hear of so few cures being made, The reason is that uncomplicated cases are rarely met with in actual practice the physician's services as a rule not being demanded until the disease has progressed far beyond the initial stage Even then it is frequently found that the tubercular infection is the least consequential of the existing lesions It is a well-known fact that unless tuberculosis is accompanied by some other pathologic condition, it usually remains localized for a long time, and the destruction of tissue from it alone is exceedingly slow It is when other micro organisms make their appearance that rapid tissue changes take place and the patient sinks quickly to the point of dissolution To stop this process of rapid necrosis in the vital organs should be our chief aim, and in order to do so, it were better for us to forget for the time being that the tubercle bacillus has anything to do with the case, and give our entire attention to the organism that is doing the actual damage In short rid the case of its complicating influences first, convert it into a condition that is admittedly curable, and then direct our energies to the original disease Can we always do this? Most assuredly we can not—but we can always try, and inasmuch as it is impossible for us to foretell the result of our efforts it is clearly our duty to give our patients the benefit of the attempt We will succeed in a certain number of cases we will probably fail in many more, at least until effort and experience shall combine to suggest improvements in theory, methods and practice In the light of past experience and present indications however it is reasonable to predict that if tuberculosis in its various forms and complications is ever to be placed in the category of curable maladies by means of medication it will be accomplished by some method within the realm of serum therapy

Snake bite —The antitoxin used for the venom of poisonous reptiles is as surely specific in its [illegible] any remedy known to medical science [illegible] drawback to its employment [illegible] curing the serum at the r sorption and action of the poison are so rapid that death is likely to result before the remedy can be obtained but where it is possible to apply the serum within eighty or ninety minutes after the reception of the sting, no fears need be had as to the outcome of the case The limitations of the application of the serum as a curative have led a number of investigators to seek for a reliable prophylactic or immunizing procedure, by means of vaccination or otherwise Chief among such experimentors are Fraser and Phisalix, who have made exhaustive researches, and claimed decided success with such substances as bile, glycocholate of sodium, cholesterin and the tyrosin of certain vegetables Calmette, however, whose name will always be associated with the antitoxin of snake venom, has shown conclusively that these substances only furnish a weak and transitory immunity by means of cell stimulation, the same as may be induced by a large number of others, and in no wise act as true antitoxins So for the present, at least, the only known safeguard for persons living in regions infested by poisonous snakes is to make sure that a supply of the antivenomous serum is kept within easy reach

Erysipelas —The writer's experience in the treatment of this disease with blood serum, has been comparatively limited, but it has been so uniformly successful in a number of trying cases that he can not help thinking that if failure should be reported it must be due to the employment of faulty serum or some equally avoidable cause Marmorek's serum is the one indicated in all stages of the disease, and a number of cases reported by me at the annual meeting of the Illinois State Medical Society on the 17th of last month most conclusively show the immunizing power of the serum, as well as its specific action as a prophylactic and curative agent The number of cases reported as successfully treated by the serum method already extends into the thousands, as every one interested in the collection of statistics can testify

Yellow fever —With the single exception of tuberculosis, there is probably no disease in which the bacteriologists of the Western hemisphere are more intensely interested, at the present time, than yellow fever We are just at that critical period of anxious expectancy when any moment may witness the end of all dispute as to the question of causation, and the true germ of the disease be established beyond all cavil And while we are thus waiting for the settlement of this one point, which we confidently hope will enable us to formulate a remedy that will place this dread disease in the column of preventable and curable maladies, it is fitting that we should allow our minds to dwell for a moment upon the names of those most intimately connected with this work Among those in foreign lands, that of Sanarelli stands out with conspicuous luster, while in our own country we have a full half dozen of equally earnest and equally intelligent workers Without detracting in the least from the fame of any of these, if asked to mention the man above all others, native or foreign, who is entitled to the palm for pioneer work in this field, for long, untiring and intelligent effort, as well as for modesty in presenting his just claims, we would unhesitatingly breathe the name of the present distinguished president of the AMERICAN MEDICAL ASSOCIATION, George M Sternberg Placing the serum treatment of yellow fever upon the same rational and scientific basis as that of diphtheria and other infectious diseases, then, we can not expect the remedy to precede a knowledge of the etiologic germ Whether this shall eventually prove to be the bacillus icteroides or the bacillus "x" (Sternberg), if these are not identical, or some micro organism yet to be discovered, remains to be seen In the meantime the Sanarelli serum should be given a thorough trial, as pronounced success or pronounced failure would materially assist in settling the question of etiology

Typhoid fever —So far no serum has been prepared that can be implicitly relied upon as a cure for this disease, although several attempts have been made The most promising one, at this time, is that of Prof Chantemesse of the University of Paris, who claims to have had marked success in a number of recent trials—noting rapid defervescene and decided improvement in the general symptoms He thinks, with a little more time for investigation and opportunity for the improvement in the preparation of the serum, it will take rank with those of well-established therapeutic value In the matter of diagnosis, however, it is quite different, the Widal test being now regarded as a perfectly reliable and practical method for the busiest practitioner It is possible to determine by means of this test, not only the very early invasion of typhoid fever, but also whether an individual has had the disease, even after the lapse of many years, in some cases The test is of especial value on account of its accuracy and the simplicity of its technique

In the brief space allowed for the discussion of this subject, it would be impossible to give the details of all that has been accomplished in the application of serum therapy to the various diseases and conditions in which it has been tried, however interesting it might be to do so Up to this time, something more than a score of diseases have been subjected to treatment by this new method, and, as would naturally be expected, with varying success In addition to those already mentioned, these include among others, pneumonia, influenza, rheumatism, cholera, cancer and sarcoma, pertussus, leprosy, gonorrhea, chancroid and syphilis, bubonic plague, anthrax, chorea and puerperal septicemia A few of these deserve more than a passing notice, both on account of the prevalence and gravity of the diseases and the promising outlook for the early discovery of efficient remedies Yersin and Haffkine have already succeeded in greatly mitigating the ravages of the bubonic plague, while numerous investigators have given us encouraging reports in regard to the probable successful management of leprosy in the near future Sarcoma has undoubtedly yielded in a number of instances to the influence of the Coley mixture, while Asiatic cholera, the depopulating scourge of many nations and of all ages, seems destined to lose its terror through the beneficent agency of serum therapy

Pneumonia —Since the discovery of the bacillus of Friedlander in 1883, a host of bacteriologists, including Sternberg, Flügge, Talamon, Fränkel, Netter, Belfanti, Gameléia and many others, have studied this germ and the micrococcus pneumoniæ crouposæ with great diligence, in the hope of arriving at definite conclusions in regard to pneumonia and its proper treatment It is generally found that mixed infection exists in this disease, and for this reason it will be necessary to pursue investigation and wait with such patience as we can command for the perfect success that we hope to meet Serums have already been used, and in some cases with gratifying success Klemperer reported six cases with excellent results, and his experience has since been duplicated by Mosny, Bonne, Emmerich and Pansini During an epidemic of pneumonia in the city of Naples, in the month of January of the present year, Pane treated nine cases of a very grave type with antipneumococcic serum The effect of the remedy is reported as decidedly good in every case, and but one of the patients died

Puerperal septicemia —When caused by the streptococcus microbe, as it is in a very large proportion of cases in this disease, is no longer the frightfully fatal affection of bygone years, for it yields in a most gratifying manner to the antistreptococcic serum of Marmorek

Streptococcal infection —If this condition meant but a single disease, however severe, instead of a number of distinct maladies and a multiplicity of complications, its presence would not be regarded with more concern than that of tetanus or snake bite But in all probability a score of such affections as these would fade into insignificance in comparison with streptococcal infection, if the full measure of its destructive virulence were known We find it in all kinds and conditions of disease, sometimes as the sole pathogenic factor, but more often as an insidious and insinuating "co-respondent" adding dangers to those inherent in the original malady, or even supplying them where none existed before Already the study of the streptococcus microbe has been productive of much valuable information and a number of diseases can be traced directly to its presence, but inasmuch as its pathogenetic power is known to vary from absolute innocuousness to the most destructive virulence, there must yet remain much to be determined The wide variation in its pathogenesis, its unapproachable extent of distribution, and the unusually attractive field it presents to the microscopist, all combine to make its study both fascinating and instructive Much confusion has been caused by the more or less arbitrary subdivision of the streptococcus into a large number of "kinds" or "species," bestowing such names upon each supposed new discovery as the fancy of the investigator would dictate Koch, Marmorek, Widal and other high authorities, however, do not recognize any of the classifications thus far made, but regard all the so called forms of the germ as the offspring of a single parent microbe, and attribute its varying pathogenic effects to such conditions as location, temperature, the kind and health of tissues involved, presence or absence of other micro organisms, etc Just why or how the same germ should cause convulsions in one animal and paralysis in another has never been explained, and possibly never will be, but as long as the same remedy, by equally mysterious methods works a cure in both, we need not trouble ourselves about the pathogeny Erysipelas, phlegmon and most cases of puerperal septicemia are caused by the streptococcus germ, and their certain and rapid cure by the proper use of Marmorek's serum is a fact so often demonstrated that it seems almost unnecessary to repeat the assertion

However important it may be to know we have so efficient a remedy for these diseases it is still of greater interest to know that the same remedy is equally successful in controlling certain complications that are more or less constant in many infectious diseases, including scarlet fever, diphtheria and tuberculosis Scarlet fever is probably always complicated by streptococcal infection and in the experience of many close observers in Europe and America, when Marmorek's serum is administered early in the attack the disease is greatly modified, runs a mild course and the patient recovers without any disagreeable sequelæ Streptococcal invasion is likewise the most constant complication attending cases of diphtheria, and no doubt many of the fatalities reported are due to this cause, and not to the toxemia produced by the Klebs-Loeffler bacillus, which may have been already overcome by the use of diphtheria antitoxin Mixed infection should be suspected and looked for in every case of diphtheria, and when found a mixed treatment resorted to as early as possible In this way the present extremely low mortality rate in this disease may be still further reduced, for without doubt nearly all of the fatal cases would show mixed infection if the proper tests were applied, and many more recoveries would occur if the proper (mixed) treatment was used

It would be gratifying to me to hold a clinic at this time and present a number of tuberculous subjects, which have come under my observation during the last two years They would all be cases of pulmonary tuberculosis with mixed infection, the predominating complication being of the streptococcal type In at least two of these cases the complicating factor was so overwhelming in extent and severity that I am tempted to refer to them as cases of *streptococcal infection complicated by tuberculosis* They had all the classic symptoms of well-advanced pulmonary consumption, and repeated examination of the sputum revealed the presence of the bacillus of tuberculosis, but always in small numbers They had stubbornly resisted anti tubercular treatment for many months, the direction of their progress was continually downward, faith had entirely deserted them, and hope was rapidly going They were even denied the questionable consolation afforded by the promise of a lingering invalidism, for their physicians had named the limit beyond which they could not survive, and the date was almost reached Microscopic examination of the sputum had heretofore been directed solely to the tubercular aspect—now it was made with reference to the complications Streptococci in vast numbers were found A complete change in the treatment was instituted, which was speedily followed by a most gratifying change in condition All measures having reference to the tubercular infection were suspended and concentrated effort given to the streptococcal invasion Marmorek's serum was given in 10 c c doses every alternate day until the streptococci all disappeared By this time there was such an improvement in the general condition that hope was immediately revived and the patients put back upon the former treatment One of them has remained constantly under my care while the other on account of distance from home, was returned to her former physician In both cases the improvement continued and now, after a lapse of nearly twenty months since the Marmorek's serum was stopped my patient reports himself in better health than he has been for many years Although there still remains a suggestion of tubercular toxemia it is too slight to cause detention from business and there has been no return of the streptococcal invasion

Aside from the many flattering re[illegible] from all quarters of the [illegible] of serum therapy as a principles, and personal application of its methods, have convinced me that its vaunted worth has not been overstated. It is based upon reason, common sense, and truly scientific grounds, and its future development can not fail to shed untold blessings upon suffering humanity.

2945 Groveland Avenue.

SOME SOURCES OF FAILURE IN TREATING LACHRYMAL OBSTRUCTIONS.

Presented to the Section on Ophthalmology at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY LEARTUS CONNOR, A.M., M.D.
DETROIT, MICH.

Accepted methods of treating lachrymal obstructions succeed in some cases but fail in others, for reasons not always apparent. Bearing on the sources of failure are the following suggestions, grouped under four heads: Constitutional disorder, eye strain, nasal disease and faulty technique.

First.—It is evident that if lachrymal obstruction be caused by a chronic constitutional disease, the best planned and most skillfully executed operation will come to naught, for surgery never cured syphilis, gout nor rheumatism, and yet observation shows that this obvious truth is not infrequently overlooked. Spyhilitic infection may diplace the puncta, obstruct the canaliculi, induce a dacryocystitis, locate a mucous patch about the mouth of the duct, cause a periostitis, endostitis or subperiosteal gumma, adjacent to or necrosis of the bony wall of, the duct, or hyperplastic processes of the bones themselves. These lesions may be found in any stage, from insignificant to gravest, singly or combined, but it is evident that operative treatment of obstruction due to any of them, would be useless unless accompanied by constitutional. More frequent though less amenable to general treatment are lesions of the tear passages, induced by gout or rheumatism or rheumatic gout and involving the mucous, fibrous or bony tissues. Their management by purely operative procedures is quite as futile as surgical operations on deposits of these dyscrasia in other portions of the body, if disassociated from suitable diet, exercise, baths and general medication. Tuberculous and scrofulous diseases do not always spare the lachrymal passages, and one who would do the best for every case of epiphora and record the fewest failures will not overlook the possibility of their presence under the most unexpected conditions. These are the most common chronic constitutional diseases, likely to produce lachrymal obstruction, though others may not safely be neglected. It has occurred to the writer to observe so many failures from exclusive operative measures which subsequently recovered under appropriate general treatment that he is compelled to emphasize the latter.

Second.—It is generally accepted that eye strain causes or may cause conjunctivitis and blepharitis, that blepharitis and conjunctivitis may induce inflammation of the lining membrane of the canaliculi and sac and lachrymal obstruction, so the conclusion is inevitable that eye strain may cause lachrymal obstruction. In its earlier stages, epiphora from eye strain is readily cured by the treatment of the diseases of the conjunctive and lids, but like the latter, it returns with subsequent eye strain, while the correction of the eye strain is followed by permanent relief of both disabilities. Less happy is the exclusively operative treatment of lachrymal obstruction from eye strain, as the mutilation of the passages added to the eye strain renders the case even worse.

It is objected that eye strain is not always attended by epiphora. Quite correct, neither do all cases have blepharitis or conjunctivitis; nor would all of a thousand persons have pneumonia if suddenly plunged into an ice cold stream, but some would. Unquestionably, there are conditions in certain individuals, which direct the disturbance of eye strain to the lachrymal passages, that are absent in others. Among these may be noted anatomic deformities of the bony walls of the duct. It is a clinical fact that lachrymal obstructions are more frequent in persons with a very broad or a very narrow-based nose. It is an anatomic fact that such faces have the bony wall of the duct flattened either anteriorly or laterally, so that the actual caliber of the passages is diminished and the more readily obstructed by morbid agents acting upon their lining membrane. It is not improbable that other congenital abnormalities determine the eye strain toward the lachrymal passages and cause obstruction. Further, it is not impossible that such deformities in some cases render failure inevitable from any or all treatment. We can lengthen a shortened leg by a mechanical contrivance, correct ocular defects in the shape of the eyeball, by lenses, but we may not hope to make round a bony lachrymal duct, greatly flattened in any direction.

Is it inquired how eye strain causes epiphora? Answer may be made: 1. By direct extension of disease from the conjunctiva and edges of the lids, to the canaliculi and duct and sac. Retention of microbes in the lachrymal lake enables them to manufacture a larger volume of debris, as well as augment their own armies, conditions favorable for causing disease of the tear passages. 2. By disturbing the position of the puncta, through muscular action of the lids in efforts to overcome the refractive defect. 3. By interfering with the natural action of the lid muscles in propelling the tears through the canaliculi and sac to the duct. The clinical proof, that eye strain causes epiphora, and its relief stops it in certain cases, is abundant, but the scope of this paper does not permit of its presentation. If seen early in their course no other treatment than the relief of eye strain is needed, but later, when strictures have formed, or dacryocystitis, or other serious complications, surgical interference must be added to the removal of the eye strain. The practical point is, correction of eye strain will remove lachrymal obstruction in some cases and benefit all.

Third.—Some failures to relieve epiphora are due to the overlooking of a morbid condition of the nares adjacent to and involving the opening of the duct into the nose. Clearly it is quite as essential to examine the terminal as the beginning of a continuous tube if we would remove all obstructions. The variety, frequency and gravity of nasal disease render it surprising that the duct is not occluded with greater frequency than is shown by clinical observation. We can not discuss the nature of the morbid condition of the nares or the means for their removal, but their importance is unlikely to be overestimated. Ophthalmic surgeons who do not treat nasal diseases need to be constantly on their guard to detect their presence, and refer the cases to one able to intelligently care for them, lest they unduly increase their failures in treating lachrymal obstructions The clinical evidence is abundant, showing that failures to relieve epiphora by lachrymal operations have been made successes by rational treatment of nasal diseases

Fourth Some failures in treating lachrymal obstruction are due to faulty technique While there are some points of this technique on which ophthalmologists differ, its general principles and most details are universally accepted Time admits only a note respecting a few points of faulty technique

1 If a canaliculus be so divided that the gap in its walls opens to the air, instead of pressing against the eyeball within the lachrymal lake, it is quite clear that epiphora will remain unchecked, and further, the chances are that it will always continue thus All operations upon canaliculi, puncta or sac should be such as to leave the opening of the upper end of the lachrymal tube within the lachrymal lake A syphon will not work unless its upper end lies beneath the surface of the fluid it is expected to drain The violation of this mechanical law renders a lachrymal operation nugatory

2 Another fault in the technique is the extensive division of the lachrymal passages, when a slight one would have accomplished the desired end Thus if the puncta be slightly everted, and so remains after removal of all disease of the conjunctiva and lids, it is quite unnecessary to slit the canaliculus extensively Long since, Dr Prout showed us that in such cases the epiphora could be effectually stopped by operating upon the vertical portion of the canaliculus alone Sometimes a simple division of the inner wall sufficed, at other times a V-shaped piece was removed from the inner wall, the top of the V being at the puncta, at other times at the base of the vertical incision, a horizontal bit of conjunctiva was removed, the contraction of the scar on healing of the wound pulling inward the open mouth of the canaliculus, so as to place it in contact with the eyeball and within the lachrymal lake If the horizontal portion of the canaliculus calls for division, operation should be limited to the least that will accomplish the end sought, otherwise failure will be courted when success was in sight

3 Another fault is the election of the lower canaliculus so frequently Unquestionably, there are cases in which choice of the lower canaliculus is imperative as when stricture lies in its course, or at its junction with the common canal, but otherwise division of the upper canaliculus affords better chances for relieving an epiphora As the lower canaliculus is larger and better located for drainage, its being left intact is important Operations upon the upper canaliculus render it easier to enter the duct by either probe or knife, because the angle to which these instruments must be elevated is smaller, hence the sac is less injured by the knife, the lining membrane less twisted or torn by probes, the points of syringe or canula more readily brought in line with the direction of the duct, and so its surfaces more easily cleansed and treated

4 Undue violence is responsible for some failures in treating lachrymal as in urethral obstruction Too great or misdirected force in using probes complicates subsequent treatment, if it does not defeat its object by tearing the lining membrane, injuring the periosteum or making false passages While these accidents may not always be avoided by the most tactful operator, because of the nature of the obstruction and fragility of adjacent tissues, they will be reduced to a minimum by exact diagnosis, and a self control that bides its time to most safely attain its object

5 Timidity in using force adequate to dilate strictures is a source of not a few failures This may spring from uncertainty as to the size or direction of the passage or the resisting power of the stricture If it be definitely settled that the point of the probe be in the axis of the passage, and that there be an opening in the stricture very considerable force may safely be employed Aside from the purely personal equation of the operator, failure is avoided by accurate diagnosis and by the use of such force as is needed for each special case

6 Rigid ideas respecting the shapes and sizes of probes diminish the chances of success in overcoming lachrymal obstructions Clearly, one who sees no advantage under any circumstance, in the use of probes larger than Bowman No 6, will not relieve a case that calls for Theobald No 16 or he who thinks that only the largest probes will avail aught will fail in the best results in a case which needed Williams No 5 or he will err who uses any probe, when the local application of hot water and the pumping through the lachrymal canals by Gould's method, of aseptic or antiseptic fluids, suffice to remove the obstruction

Doubtless cases have best been treated by each different kind of probe and each size so that he is wisest who selects his probe because of its fitness for a particular lachrymal canal rather than attempts to make the canal adapt itself to his probe the shoe ought to be made for the foot, rather than the foot made to adapt itself to the shoe

Necessarily, small probes only are admissible through the undivided canaliculus larger ones when the sac must be opened, and it be desired to make the duct large enough for the flow of tears by simple gravity from lachrymal lake to nose for this latter purpose Theobald's probes have served my needs admirably Williams probes with olive shaped points and small flexible shanks have an especial value in cases of moderate strictures, calling for little pressure to induce absorption, and for locating and defining the same

They have an admirable facility in gliding about obstructions with the least injury to adjacent structures Bowman's probes occupy an intermediate position, and are especially useful in promoting absorption in moderate sized ducts Failures will be less frequent, as each operator uses common sense in the adaptation of his probes to the especial features and different stages of each case

SUMMARY

It is urged that fewer failures will attend the treatment of lachrymal obstructions, if the operator in each case

1 Recognizes and treats the chronic constitutional disorder which caused the obstruction

2 Removes all eye strain

3 Makes sure that the nares adjacent to the opening of the lachrymal duct are rendered healthy

4 Perfects himself in a faultless technique

TREATMENT OF CHRONIC SUPPURATIVE DACRYOCYSTITIS

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo , June 7–10 1898

BY A E PRINCE, M D
SPRINGFIELD ILL

In response to an invitation from the Secretary of the Ophthalmologic Section of the AMERICAN MEDICAL ASSOCIATION, I send the following brief paper, the purpose of which is to present the method I employ for obliterating the lachrymal sac

During the earlier years of my practice I tried medication, irrigation and large probes, but the percentage of relapses was so great that I finally discontinued endeavoring to preserve the patency and restore drainage in all cases of chronic suppurative dacryocystitis For the benefit of those who conclude, in any given case, to obliterate the lachrymal sac, rather than to attempt any of the various plans offered for the preservation of drainage, I here offer a very simple, and at the same time a very satisfactory method of dealing with this question, which has not disappointed me in its results for several years My procedure is as follows Introduce a probe through the canaliculi into the lachrymal sac Direct the point toward the skin so that the point of pressure may be discovered at the surface (Stevens' tenotomy hook serves well for this purpose) Incise the skin over the probe, and enlarge the opening upward and downward the entire length of the sac Lay open any sinuses which may exist Apply a saturated solution of monochloracetic acid by means of a cotton applicator over the exposed surface of the sac and sinuses Pack the wound with iodoform, and keep it packed until healing is complete The iodoform remains in situ, and prevents the cutaneous wound from healing before the bottom is closed

I have tried excision of the lachrymal sac and application of other forms of caustics, and the results in comparison have led me to prefer the monochloracetic acid to any other agent I have packed with gauze, and the result has not been so satisfactory

For years I have used pulverized iodoform to pack the cavity of the globe after evisceration, and the behavior of pulverized iodoform in this cavity led me to believe that it would serve an equally good purpose in packing the lachrymal sac

THE USE OF LARGE PROBES IN STENOSIS OF THE LACHRYMAL DUCT

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo , June 7 10 1898

BY MELVILLE BLACK, M D
PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY GROSS MEDICAL COLLEGE DENVER COL

In the presentation of this subject no reference is made to such mild cases of lachrymal stenosis as can be relieved by probing the canaliculi with small probes, followed by syringing, nor to cases dependent upon closure of the lower opening of the duct by pressure from the inferior turbinated body The class to which I desire to call attention is that of true stenosis of the lachrymal duct, in which mild measures and nasal treatment are of no avail

In order to pass a large probe down the lachrymal duct it is first necessary to slit a canaliculus It is very important that the canaliculus of lesser function should be selected The punctum and canaliculus of the lower lid unquestionably have greater function in draining the palpebral aperture of fluid than have the corresponding parts in the upper lid Once the canaliculus is slit and its punctum destroyed, its suction power is lost, and it ever after acts in an indifferent manner If the lower canaliculus is slit, probes passed and the duct otherwise treated until it is thoroughly patent, this eye will never again be free from epiphora when exposed to inclement weather On the other hand, if the upper canaliculus is chosen as the means of gaining access to the lachrymal duct, it will be found that after the passage is rendered patent the lower canaliculus will be able to keep the eye free from tears I deem this point of great importance and believe that the many failures in the cure of lachrymal duct stenosis are due to the destruction of the suction power of the lower canaliculus

If probing the lachrymal duct for the relief of stenosis is to be of any advantage we must observe the same rules as in treating stricture of the urethra The duct must be dilated *ad maximum* It is my custom to pass, at the first sitting, the largest probe that can be introduced The canaliculus in the upper lid is slit with a Graefe cataract knife, with the aid of a Bowman's grooved director The director is passed through the canaliculus, then turned to the vertical and passed to the bottom of the lachrymal sac The Graefe knife is used with the director in the vertical position The director is now removed and a graduated probe introduced, to determine the size of the duct If a marked stricture is encountered, an Agnew's knife is passed down the duct and the stricture cut If no stricture is found, the Agnew knife is not used The size of probe that the canal will admit can be fairly well judged by the passage of the graduated probe I find that it is rarely that a No 10 Theobald probe can not be passed If the probe first passed is loose in the canal one after another of larger size should be tried until one is found that is passed with difficulty and completely fills the canal Strong pressure should be exerted on the mucous membrane throughout the entire length of the canal It is my custom to examine the nose to see that the probe is well down in the inferior meatus If it is not, this or a smaller probe is forced down until it can be seen or felt beneath the inferior turbinated body The probe is allowed to remain *in situ* about ten minutes It is then withdrawn and the lachrymal passage syringed with a saturated solution of boric acid until bleeding ceases The patient is then sent home and instructed to apply lead and opium wash on pledgets of lint which have been cooled on a block of ice This should be done almost continuously for 24 hours At the expiration of this time I inject, with a lachrymal syringe, into the duct a few drops of 10 per cent solution cocain A probe a size smaller than the largest one passed the day before is then passed The negative pole of a galvanic battery is then connected with the probe, the positive pole being placed in the patient's hand Then from two to three milliampéres of current is turned on for ten minutes When the probe is removed it will be found to be very loose, owing to the electrolytic action of the cathodal current The lachrymal passage is syringed free of blood as on the day previous There is usually a little bleeding after the removal of the probe, for the first four or five days The patient is instructed to use the lead and opium wash for four hours in the same manner as on the day previous On the third day the same probe is passed, unless it is found to be loose, in which event a size larger should be used The 10 per cent cocain solution should have been previously used to relieve the pain The probe is allowed to remain in the passage ten minutes After its removal the syringing is practiced as before A few drops of 25 per cent solution ichthyol in water are now syringed into the passage The probe is passed daily for about ten days, accompanied by the syringing of saturate solution of boric acid, and ichthyol solution The largest probe that the duct will take should be used At the end of the first week the battery should be again used in the manner described After the first ten days the above procedures should be carried out three times a week for two weeks, then twice a week for two weeks After this it should be done according to indications until all epiphora ceases The use of electricty should be practiced every week or ten days for the first six weeks, and after that according to indications It is impossible to lay down hard and fast rules in these cases I generally say to my patients that a cure may be expected in two months I am frequently able to dismiss them sooner My experience has been that a No 10 probe can be passed at the first sitting, and that in a few days a No 13 or 14 can be passed I have passed the No 16 probe in a few cases

When blenorrhea or phlegmon is present I expect complete disappearance of these symptoms during the first week When superficial necrosis of the lachrymal bones exists, treatment is sometimes more protracted, and has to be persisted in until the necrosed bone is absorbed In cases of fistula with sequestrum of bone it is necessary to cut down and remove the sequestrum

The three points that I desire especially to emphasize are, the opening of the upper canaliculus, the use of the largest probes possible of passage, and the electrolytic action of the negative pole of the battery

THE VALUE OF LARGE PROBES IN THE TREATMENT OF LACHRYMAL STRICTURE

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo June 7-10 1898

BY H O REIK, M D
Instructor in Ophthalmology and Otology Johns Hopkins University and Assistant Ophthalmic and Aural Surgeon, Baltimore Eye Ear and Throat Charity Hospital
BALTIMORE MD

Knowing that the treatment of lachrymal stricture would be one of the subjects of discussion at this meeting, and knowing also that there exists among ophthalmic surgeons a very wide difference of opinion concerning the use of large probes for this condition I thought it might be of interest to review and report upon the cases treated under the observation of Dr Samuel Theobald, whom all of you know as the author and chief exponent of the really large probes At the outset it would seem advisable to consider what is meant by "large probes, for notwithstanding the fact that Dr Theobald has so frequently explained this point and insisted on the difference between his probes and those of Bowman we still see in literature frequent references to Bowman s No 6 as a large probe Then again, the probes obtained from the instrument-maker under the name of Theobald are not always copies of the original model I have seen surgeons using what they supposed was a Theobald probe, but which in reality bore but slight resemblance to the proper thing Some of them perhaps all of them, are of proper size, but frequently they are improperly curved, or present extremities that are either very blunt or very sharp, and thus the possibility of delicate manipulation is precluded

When properly constructed, the probes should have a conical-shaped point the smallest should have a diameter of 25 mm, the largest, No 16, a diameter of 4 mm and the difference in diameter between successive numbers should be 25 mm The smaller sizes —Nos 1 to 8—should be made of coin silver, while the larger ones—9 to 16—may be made of pure silver or preferably, aluminium I will pass around for inspection a set made according to the above directions, which were published by Dr Theobald

The cases which, through the kindness of Dr Theobald, I have had the privilege of studying comprise in all 130—63 of which were seen in Dr Theobald s private practice and 67 in his service at the Johns Hopkins Hospital and at the Baltimore Eye, Ear and Throat Charity Hospital, in each of which last named places some were treated directly by him and others by his assistants The 130 cases are not selected ones beyond the point that they all received treatment with probes ranging between Nos 12 and 16 Of course a great many more than 130 patients appeared in whom the diagnosis of lachrymal stricture was made, but as they refused treatment or did not continue beyond the smaller sized probes, they were not considered to be of much importance in this paper In the cases here included the condition of affairs at the beginning of treatment consisted of persistent epiphora in all blenorrhea of the sac in all but a few, lachrymal fistula in some, and chronic blepharitis or conjunctivitis in many The pathologic lesion in probably all of the cases was one or more strictures in the nasal duct

We find that of all of the patients seen in whom the diagnosis of stricture of the nasal duct is made, about 50 per cent either decline operative treatment or fail to return after the first probing These patients consist largely of nervous men, who, after hearing the statement we usually make before instituting treatment, decide that they will not undertake it It is our custom to explain to all these patients that the treatment, despite the use of local anesthetics will be more or less painful and necessarily protracted This probably has the effect of scaring off some of them About 15 per cent of all who undertake the treatment fail to carry it on to the end They will receive the probes up to perhaps Nos 10 or 12 and then as the epiphora has ceased, they are disposed to stop treatment before we are willing to pronounce them cured Of the cases reported here, which include a number of children 75 per cent received probing up to and including No 16 About 50 per cent of all the children under 12 years of age received No 16 and 50 per cent of the remainder received No 15 [illegible] only 25 per cent of the children under 12 who were allowed to stop short of that point

What have been the results in these 130 cases in which the large probe treatment was thoroughly carried out? All but 3 were regarded as cured when treatment was stopped I may say here that the length of time under treatment [illegible] some patients being discharged at the end of a month or six weeks, while others were kept under observation more than a year Of the 3 referred to above, one was a particularly obstinate case in which several distinct strictures could be felt in the duct, another was much improved, though not cured, the stillicidium being only slight and occasional, and the third was a case in which the stricture resulted from traumatism In this last case the treatment was very painful, the scar tissue being difficult to overcome, and the patient did not continue his attendance as long as we desired He was vastly improved, a fistula which was present having healed and the blenorrhea of the sac which accompanied it being decidedly lessened

It is practically impossible to learn the whereabouts of all these patients today, as most of them were dispensary cases and have moved one or more times An effort was made to communicate with them in order to learn their present condition, and we succeeded in quite a fair degree Perhaps a dozen cases were heard from and their condition noted within six months from the cessation of treatment, but we will only consider the 39 cases which have been seen, or from whom reports have been received, at periods varying from one to eight years after the cessation of all treatment Thirty-seven of them remained cured when last heard of, as follows Ten last heard from after the lapse of one year, 11 after two years, 2 after three years 6 after four years, 1 after five years, 2 after six years, 4 after seven years, and 1 after eight years If the two which have relapsed be added to the three in which a cure was not at any time claimed, we have five out of a total of 130 in which the treatment may be said to have failed, although this would be an extreme statement, for in both of the relapsed cases the patients enjoyed a period of comfort, with absence of epiphora, of more than two years It would seem, then, that if the treatment is thoroughly carried out, we may expect to effect a cure in about 95 per cent of the cases, and a relapse may occur in about 5 per cent of these

I desire to express my thanks to Drs Hunter McGuire, Jr, and James Bordley, for much valuable assistance in following up these cases and preparing the statistics

DISCUSSION ON PAPERS OF DRS CONNOR, PRINCE, BLACK AND REIK

Dr D S Reynolds—No more interesting subject could be found, for the reason that we know so little about it I listened with attention to Dr Connor's paper because it seemed to me to be very timely I have never seen lachrymal disease in the perfectly sound and healthy individual I have serious objections to entering inflamed mucous lined channels with probes and I utterly abhor the idea of the Theobald probe, 4 mm in diameter I submit it to any gentleman who has ever examined the bony passages of the lachrymal apparatus, that a probe of that diameter can scarcely be passed in the Caucasian subject I am aware that many negroes have lachrymal passages of large diameter, but I am sure that a probe of more than 2 or 3 mm in diameter can not pass without doing damage to the passages of a white man There is no cause of epiphora that can not be discovered by careful examination If it be due to some destruction of infiltrated tissue arising probably from come trouble in the nose, as most of these cases do, it can be easily found if sought for I have heard a great deal about the innumerable cures of systematic probing, but I have never seen any of them that will wear well I have seen many cases of epiphora that by carefully advised constitutional agents and the confining of local treatment to the diseased membrane of the nasal cavity result well. I take the Anel's syringe and a 2 per cent solution of sodium chloride and try to pass that through the canal instead of the probe, and if the fluid can be passed through the canal where no suppurative changes are present I hold that to be a contraindication for any other surgical measures

These cases of Professor Holmes belong to a special class. They are not only chronic cases, but people with constitutional taints or who have been treated by harsh means that destroyed the duct and canal Primarily epiphora calls for no probing, and the presence of the condition merely suggests abnormal conditions that exist in the nasal apparatus

Dr Casey A Wood, Chicago—I would like to point out to you that even where it is proper to use probes, and even where a cure may be looked for after a considerable time, failure is exceedingly common It is not always possible to discover whether probing has succeeded in many cases because these patients become tired after a while of having their ducts probed and cease to appear at the office of the surgeon It interested me some time ago to discover the reason for the non appearance of these patients The excuses were found to be trivial, the patient is obliged to leave town or disease has occurred at home, and there are many additional reasons that are given for discontinuing the treatment That this form of it may be successful, one must, as Dr Reik has pointed out, often continue it for months or in some cases even for years One of the principal reasons for their deserting the oculist's office is the relief the patient gets at the outset The epiphora disappears, the symptoms improve and the patient feels that he is cured and does not think it necessary to come back In the city of Chicago men and women seem to have very little time on their hands and can not continue to visit the office for weeks to undergo a painful treatment, even though it may be good Now I want to point out a way in which, in the majority of instances, these results can be improved It is my practice not to treat these cases in my office for more than two or three weeks, and one can usually induce them to come that often, but during those two weeks I do all the accessory work that I consider necessary, treatment of the nose, etc, with the introduction of as large probes as possible, and I then teach the patient to use the probes himself and allow him to continue the treatment indefinitely at home Such a plan will be found to succeed in the majority of cases

Dr Frank Allport, Chicago—This is a broad subject and one that can hardly be fully discussed in the length of time we have to talk I am sorry we did not have an opportunity to hear more of Dr Holmes' paper, because we only got a glimpse of its value As Dr Reynolds said, I presume he only operates in this radical manner in those cases in which all other means have first been tried I think there can be no question that we all feel alike on this subject, that we all have cases that do not get well and we can only wonder why Some use small and some large probes I think one reason why we do not get better results in these cases is because a great many of them are treated along stereotyped lines We think the first thing to do is to rip up the apparatus without any regard to its normal physiologic condition and pass probes that are as large as can possibly be put in My practice formerly was to limit the probes only to the capacity of the duct, but a long line of failures led me to change

I believe that 80 or 90 per cent of the cases of epiphora originate in the nose and should be treated primarily from that standpoint Most surgeons practically ignore this point I also feel as Dr Reynolds does, that I have simply learned to abhor and detest the large probes I no longer use as large a probe as I can, but as small a one as is adequate, and since I commenced that practice I have had better results Some surgeons seem to think all that is necessary is to have a large hole down which tears may flow, but you may have a canal large enough to pass a No 16 and if the physiologic suction apparatus is destroyed the tears will stand in the sac and not go down You must have the physiologic condition of that apparatus retained I never cut the duct if I can possibly get along without it I try to preserve the physiologic function from the punctum to the termination of the nasal duct and a large probe, 5, 6 or possibly an 8, can be introduced after stretching without increasing the punctum I have here a little instrument like a hollow probe and containing a concealed knife, which can be passed through the stretched punctum and then made to expose the knife and cut the stricture in the duct (Exhibiting the instrument)

Dr J E Minney, Topeka—I have no doubt as to the success of Dr Reik's work nor of these gentlemen here advocating the Theobald probes and those of you who remember Dr Derby's work will remember what sized probes he used, the largest as big as my little finger These men succeed and it is astonishing that in my practice I have failed to use anything larger than a Bowman No 8 and I find I have treated 250 cases That may seem large but it is a fact A point that impresses me is this, that every oculist must be more or less of a rhinologist unless he wishes to divide his fees with some one else He must know something of everything and everything of some one thing

I have no use for the lotion of opium and lead I use hot water and boracic acid A 5 per cent solution of cocain I have found sufficient Electricity I have not used Is it not possible that we create a great many infidels by our use of so many things when a much simpler practice would be as good?

Dr George M Gould, Philadelphia—In reference to these troubles I simply wish to emphsize one or two points which I overlooked in my early practice and which some of you may have neglected I have no hospital or dispensary practice, hence do not see so many of these cases In the last two years I believe I have had occasion to use probes only once I have found that there are a large number of cases in which epiphora is simply due to an excess of tears and not because the duct would not carry off the normal secretion I think eye strain is the primary cause of these As the result of long continued eye strain you have chronic conjunctival trouble with an excess of tears and if you cure the cause the epiphora will disappear Several years ago I published a little article, and I have used the method there suggested probably a hundred or more times, and have never failed in any case in which there was not an organic stricture The method consists in submerging the eye in an astringent medium, the contents of the duct being first forced into the sac by pressure and then by filling the sac with the lotion and pressing downward it escapes into the duct You can teach patients to do this at home and let them report to you once a week

Dr J L Thompson, Indianapolis—There have been some very excellent papers presented to us and we have not time to consider them all Dr Connor's paper was very excellent and Dr Gould has in his remarks led me to think of the condition we so often find from excessive smoking, etc In that class of men who are given to smoking, drinking, gambling and other things that we do not think right, there are many cases of epiphora that are cured by relief of the strain

I have been trying to learn something about lachrymal troubles for 26 years and I notice the gentlemen who introduce new methods have excellent results, while I do not have one fiftieth part of the success they report with the same methods I do not know why, for I do not think I am so awfully stupid

At the last international Ophthalmologic meeting at Edinburg Argyll Robertson said that Dr Cooper and not Dr Theobald was the originator of the large probes I would like to ask Dr Reik if he can tell us anything about that point.

I have used large probes, some large enough for a rhinoceros and have thought my cases cured, but in a year or so some of them write "I believe you promised me a cure " I know how to answer that letter, because I never promised anybody a cure in my life I believe the majority of these cases will come back in a few years just as bad as ever Sometimes I use the style, allowing the patient to put it in at night and take it out in the morning Mine has been a private practice entirely I asked one of the gentlemen at Moorefield's "do you cure these cases?" and he said that many of them go to other hospitals after a time I usually tell my patients now that I am not going to perfectly cure them

Dr T A Grigg, Butte—We could not have a more timely series of papers, though we have all had much trouble over the treatment of lachrymal diseases Laying aside those cases due to eye strain, slight catarrhal troubles and the like, and taking up these cases of pure organic obstruction, the first thing I do is to dilate the punctum and try to pass the boracic acid solution through the duct by means of an Anel's syringe I examine the nose thoroughly and sometimes divide the strictures and pass as large a probe as convenient, from 6 to 8 Bowman Usually in these cases that can not stay I use a canula about as large as 6 or 8 Bowman probe and leave it in place from three to nine months, with very satisfactory results There is a pathologic law that an intermittent pressure will produce hypertrophy and that continued pressure will produce atrophy, and my theory is that if you can use a lachrymal canula you get a pressure on all sides and cause an atrophic condition that will relieve the obstruction With this method of treatment I have had very satisfactory results Where there is a purulent condition I often omit the canula for a few days and syringe the duct with a weak solution of nitrate of silver I have some cases treated five years ago which are all right at the present time

Dr J O McReynolds, Dallas, Texas—I should like to express my gratitude to the gentlemen who have contributed papers or discussion on this subject, for no cases have given me more trouble than these The ultimate object to be accomplished is by no means to secure a sufficiently large nasal duct, as Dr Allport has said, and that point ought to be published further than it has been In harmony with what Dr Gould has said, I would say that I have been able to cure some of these cases by diligent attention to the condition of the conjunctiva and by giving the correct glasses I have not simply given an antiseptic solution to be used occasionally, but very frequently during the day This keeps the duct cleansed out, and we have then the best condition possible for relieving the pathologic state I have even sometimes given patients a syringe which they could use themselves

Dr R F Le Mond, Denver—This is a subject we need to have discussed and experimented on very much, because when we get hold of these bad lachrymal cases we are like the man who got his hands full of a wildcat, he wanted somebody to loose his hands I think I have gained several good points by hearing this discussion today I want to say that a method which I have been using for the last eighteen months, and which has acted very well in many cases, though not so well in others, is the use of a hollow probe of pure lead, which I introduce into the duct curved so as to fit the canal, and let the patient wear it for a month, washing it out two or three times a week

Dr E C Ellett, Memphis—I did not hear the papers and do not know how much was said about the advantages that lead styles possess over any perforated canula I have never yet seen a canula that would drain a lachrymal passage Lead styles are so convenient, so easily fitted to the case, and secure much better drainage than you can get through the lumen of a canula.

Dr L W Fox, Philadelphia—I wish to add my experience in the treatment of lachrymal obstruction, which every one has found the bane of ophthalmic surgery I belong to the school that uses the large probes and believes in them I just heard the remarks about drainage with the canula After many years of experience I have partially evolved a canula which I wish to present It is a silver tube, modeled on those that have preceded us, and I have found it as satisfactory as anything I use For many years I have used the large Theobald probes The lead style has always been a favorite of mine immediately after operation, using that for three or four days and then following it up with these silver canulæ In the large manufacturing districts about Philadelphia we see many of these cases, sometimes having ten or twelve a week at our clinic, which consists of 4000 general cases a year Where there is ordinary epiphora and the mouth of the canal is closed, I use the probe to dilate to the fullest extent possible, and in those cases I have success, whereas if the stricture is farther down, or there is a latent abscess, the operation of passing the Weber or Stilling knife and dilating to the fullest extent, is followed with the lead style and then with these canulæ While I was house surgeon at Moorefield's we had an enormous number of cases, and the Cooper method was followed exclusively In Paris they used the narrow probes

Dr Wood—How long do you leave the canula in?

Dr Fox—For six months I take them out occasionally and wash the duct with a solution of boracic acid I find I am often obliged to keep in these canulæ and to probe from year to year

Dr W H Wilder, Chicago—I think it is an encouraging sign of the times when we hear so many men advocating the conservative treatment of these cases, and I dare say many of us would be willing to predict that the time will come in a few years when the indiscriminate probing of lachrymal cases will be relegated to the past I dislike to see a surgeon reach for the Bowman knife as soon as an epiphora case comes in We should endeavor to preserve the integrity of the canaliculus, once it is slit up we can never replace the delicate mechanism

I believe most certainly that many of these cases could be relieved completely if the conservative treatment were adopted from the beginning At first there is no organic stricture whatever It is merely a catarrhal condition and the duct is obliterated by reason of the swelling of the mucous membrane, and temporizing measures for a short time even, without the slitting of the punctum, will in very many cases suffice

I think Dr Holmes' specimens will illustrate very well that in some of them you could introduce the Theobald probe, but in many lachrymal ducts such probes would do great damage

Dr Kegley—In regard to teaching the patients to pass probes themselves, it seems to me the difficulty with all of us has been that we do not know when to discharge our patients About the first thing I do is to teach the patient to pass the probe himself, and as soon as I do that I discharge the patient and the rest is with him I have perhaps fifty cases now that I have been watching for eight years and every one of those patients is satisfied I never go above a No 8 probe, for I think that is large enough to drain off the secretions

Dr LeMond—I want to ask if any of the gentlemen present have tried the obliteration of the sac by means of the galvanic cautery?

Dr Connor—I have been extremely interested and instructed by these papers and the discussion that has been presented upon them In the whole range of ophthalmology I know of no class of diseases that have given me so much trouble At the same time I think the way to get out of the trouble is to study its source, and I am convinced that if the members of this Section look at the question from that standpoint they will find their results increasingly better If they apply the same common sense to this class of troubles they do to the extraction of cataracts, their results will become as good as in that case The earlier the cases are seen the better the results, and by inducing the patient, through the general practitioner, to undergo treatment before organic changes have occurred, we shall diminish our sources of failure As I remarked respecting probes, I think they should be used on the same general law that we use instruments anywhere I have once in a while found a case where everything else failed me and the Theobald probe has brought success My conviction is that one of the forces by which the tears are discharged through the canal is the air going in and out over the end of the tube That is according to the idea of mechanics, consequently I never use a large probe if I can help it, and only when I am compelled to make a large opening in the sac I think the use of hot water is helpful in some cases I think, as Dr Thompson stated, it is well to have the patient understand at first that one passing of the probe will not cure them They must not expect to get well in one or two weeks, and if they are not willing to undertake what is necessary for a cure it is better not to have anything to do with them

Dr Black—It seems to me that the conservatives have it, and I want to align myself with them While my paper may seem to have placed me among the radicals, at the same time you must remember that I made the statement that it was not the cases capable of being treated by mild methods that I was dealing with My paper had to deal with difficult cases, and in my experience these have been the cases where there was purulency of the sac Where there is simple stenosis, especially at the upper end of the lachrymal apparatus, I believe that mild methods will accomplish a cure in a large percentage of cases, and that we should discourage the consideration in all cases of the general physical conditions I would not for a moment advocate It goes without saying that any man doing special work should not fail to recognize that he is still a practitioner of medicine It does seem to me, however, that it is within reason that if it is necessary to pass a probe we must take into consideration the capacity of the passage To dilly dally around in the duct with a little bit of a lachrymal probe serves to tickle it and accomplishes nothing We must put a probe down for the purpose of producing pressure, I can conceive of no other reason for introducing, and if we want pressure let us use a probe large enough to fill the passage In my experience during a service in the Manhattan Eye and Ear Hospital in New York, where I had the opportunity of observing other men using different methods, I was strongly impressed with the fact that the men who never used probes larger than No 8 were the men who had these cases continually on their hands The men who were inclined to use rather energetic means in these severe cases accomplished something and their cases showed marked improvement and were soon discharged My experience has been that when I have one of these marked cases of obstruction mild measures accomplish very little

Dr Reik—I did not attempt in my paper to consider the value of large probes in the treatment of lachrymal stricture, further than a brief statement of our results in those cases where the large probe treatment had been thoroughly carried out The 130 cases there considered contained none of those mild cases of epiphora due to obstruction of the puncta, reflex irritation or slight catarrhal troubles, but all belonged to that class in which there is an organic obstruction in the duct and, as I stated, in most of the cases we were able to locate by the sense of touch one or more distant contractions Our cases were followed up for periods varying from one to eight years, and I know of no other method of treatment for this class of cases which will show 95 per cent of cures Dr Reynolds attacked the large probes in his characteristically forcible style, but I think it would not be difficult to demonstrate to him the ease with which a 4 mm probe can be introduced into the duct of the Caucasian subject, and I think, furthermore, if he will measure the lachrymal ducts of any large number of subjects he will find the average diameter considerably larger than he is at present inclined to believe Dr Wood's plan of teaching the patient to use the probe himself is a good one, and we have made use of it in many cases, especially where the patient lives at a distance and can not make frequent visits to us Dr Allport's experience is entirely at variance with ours It is true that after the use of probes to Nos 8 or 10 epiphora ceases in many of these cases and the patient is inclined to call it a cure, but a study of our records shows that if these cases be followed, not simply for a few of the summer months, but for a year, so as to include the winter months, numerous relapses will be noticed In regard to Dr Thompson's question concerning the authorship of these probes, I would say that I am familiar with Argyl Robertson's statement, but he gave no dates in connection with Dr Cooper's claim of priority and the question can not be settled yet

REPORT OF TWO CASES OF ACUTE GLAUCOMA

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10 1898

BY H BERT ELLIS, M D

LOS ANGELES CAL

On Jan 11, 1895, there called upon me Mr G M, aged 51, a minister by profession, who gave the following history

On January 8, while eating supper with his family, a little piece of dry toast choked him and caused a coughing-spell, during which something seemed to snap in his right eye Shortly afterward his eye became very painful and watered freely The lids began to swell and the eye to become inflamed, and his regular physician was called in, who gave him an atropin and cocain solution As the swelling and redness continued to increase, he was referred to me by his physician I found both the orbital and palpebral vessels very much injected, especially of the lower portion of the eye, the pupil very large, the tension slightly reduced, so that I thought that the dilation of the iris was the result of the atropin and cocain, but the use of a half per cent solution of eserin failed to contract the same The lens was dislocated downward and backward Under a light pressure-bandage and rest for twenty-four hours, the lens regained its position, but the pupil was still irregular and large, the lower part of the lens cloudy In so far as vision was concerned, that eye was almost blind, the patient only being able to distinguish light, the tension was slightly less than that of the other eye On the 18th, he could distinguish the form of objects, on the 25th he could notice individuals, but could not tell their features On this date, the patient was free from pain, the swelling of the lids had almost entirely gone, and the injection was greatly diminished I tested the vision of the left eye and found it to be 3/40, which was brought up to 6/7 by a + 5 5 spherical, combined with a + 5 cylinder at 180 degrees and he could read number 50 D, with an addition of + 3 spherical On February 1, the lens was quite cloudy The tension had increased and the cup was glaucomatous, vision entirely gone I saw the patient frequently during the spring, kept him upon eserin and mild astringent drops, and there was no material change in his condition I corrected the error of refraction of his left eye and cautioned him in regard to the use of the same On October 29 my notes say Lens clear slight haziness of cornea tension normal Disc cupped, with the vessels passing over the edge and disappearing I warned the patient to be very careful about using his eyes, that he might have a similar attack with his remaining useful eye, and requested that on the first intimation of pain he report I saw him occasionally during 1896, the tension slightly increased in right eye as time went on He was doing his pastoral work faithfully, but abstained from reading more than he absolutely had to On April 5, 1897, he came to my office, being led by his wife, and gave the following report For about a week he had been suffering from a severe cold in the head and, accompanying that, a slightly inflamed eye which he thought, as the cold improved, would pass off There had been considerable pain and five days before reporting, he became almost blind but was too miserable to report and still clung to the idea that it was only inflammation and would soon pass off I found the tension of the eye ball + 3 pupil very much enlarged, and the media so turbid that an ophthalmoscopic examination was unsatisfactory I performed iridectomy at once, which gave him slight vision, that is, with a — 1 spherical glass, combined with a + 5 cylinder at 125 degrees, he could read 6/100, sufficient vision for him to get around among his parishioners and about the city

Miss J S, aged 24, came to me on the morning of Sept 18, 1897, with her family physician, and gave the following history On the evening previous, she had an acute pain in her right eye followed by sudden blindness The conjunctiva was inflamed with marked photophobia, increased tension and dilated pupil I could elicit nothing as to previous history outside of her usual mode of life Diagnosis acute glaucoma Treatment, immediate iridectomy Satisfactory progress, and on November 1, with a + 2 75 spherical combined with 4 5 cylinder at 130 degrees, it was 6/24, with a — 1 cylinder at 120 degrees and a 2 5 cylinder, she could see 6/20 + On Dec 8, 1897, I prescribed for her a — 75 spherical combined with a + 3 25 cylinder at 30 degrees, which gave her vision of 6/15

This case is a typic case of acute primary glaucoma The first case is peculiar, in the first attack, in having a partial dislocation of the lens as the primary cause of the glaucoma, whereas the attack with the second eye seems to have originated *de novo*, or at least was provoked by an acute cold

I present these two cases in contrast, simply to illustrate the conditions that we have to meet constantly in private practice There is nothing extraordinary in either diagnosis or treatment One is typic, and one departs very materially from the usual conditions

A CASE OF HEREDITARY GLAUCOMA

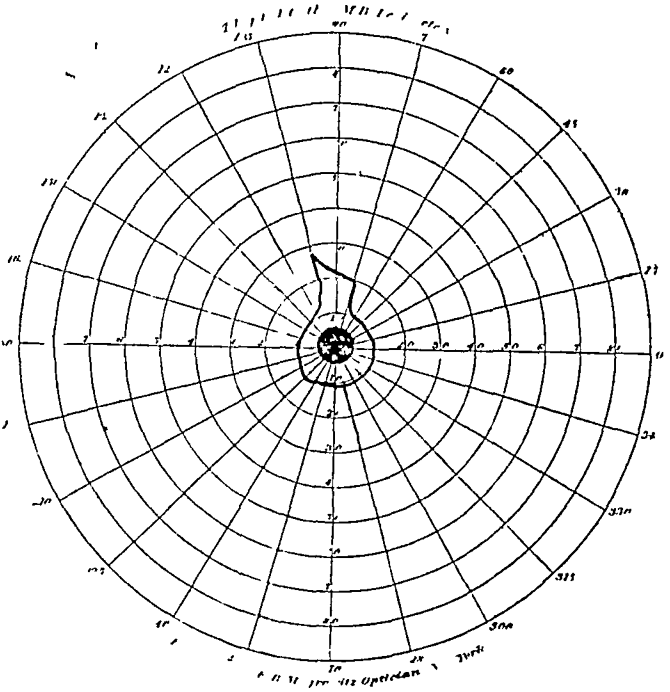
Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10 1898

BY HERBERT HARLAN, A M, M D

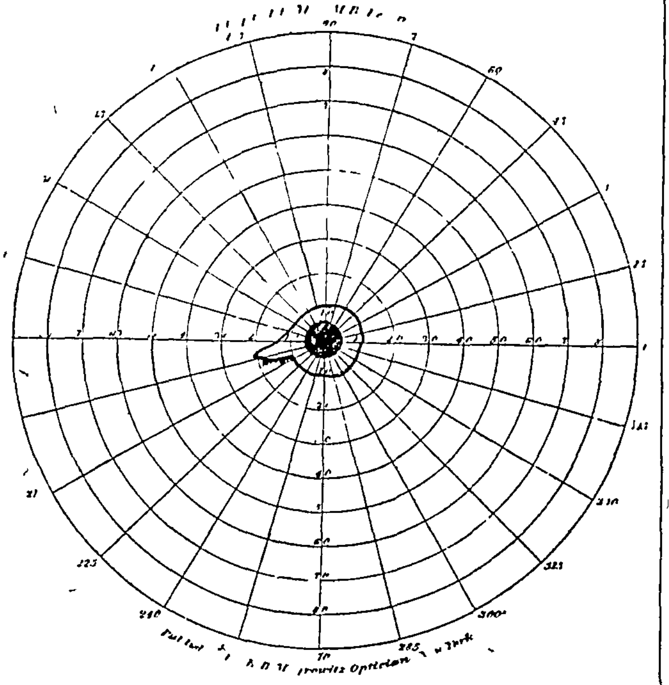
BALTIMORE

Before this Section, at the New Orleans meeting in 1885, I reported a case of glaucoma the patient being one of the fifth successive generation in which the disease had appeared That case C L B, aged 17, consulted me in March of that year The following is the family history taken from the previous report

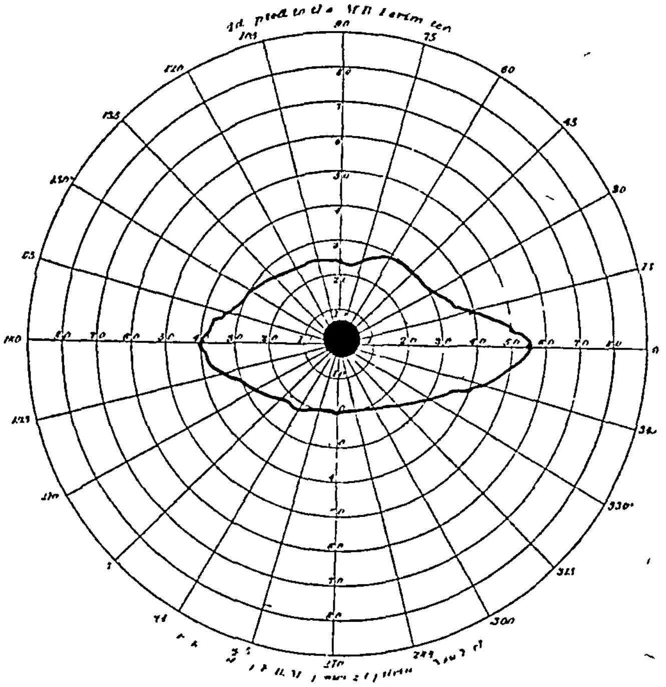
"Her mother, who accompanied her [illegible] old, and absolutely blind Both anterior chambers are obliterated and the pupils closed She states that at 19 her eyesight began gradually to waste away She saw halos around the lamp A year later she had inflammation in the eyes which the doctors called cold and treated with drops and blisters After a while the eyes got better Then another attack of inflammation came on, and she has been blind ever since Never at any time was there much pain The mother's father lost his eyes in the same way, beginning at the age of 18 This is the history of the maternal great grandmother and great-great grandfather I was unable to trace the family history farther back, but from that given there can be little doubt that glaucoma has been transmitted in direct line for five generations, the age of onset being about the same A maternal uncle at 35 years had pain in his eyes and head, and in three years his sight was entirely gone A maternal aunt, who saw perfectly till she was 18 years old, and never complained of pain, was suddenly found by the family to be blind (This was the mother of the patient whose case I am about to relate today) Two uncles and an aunt, all over 55 years of age, see well One cousin, now at a blind asylum, began to lose her sight at 16 Sight in the left eye was gone before it was found out The other slowly followed Never complained of pain Another cousin was operated on four years ago by an oculist of Baltimore One eye was removed altogether, and on the other an iridectomy was done, and with this she now sees ”



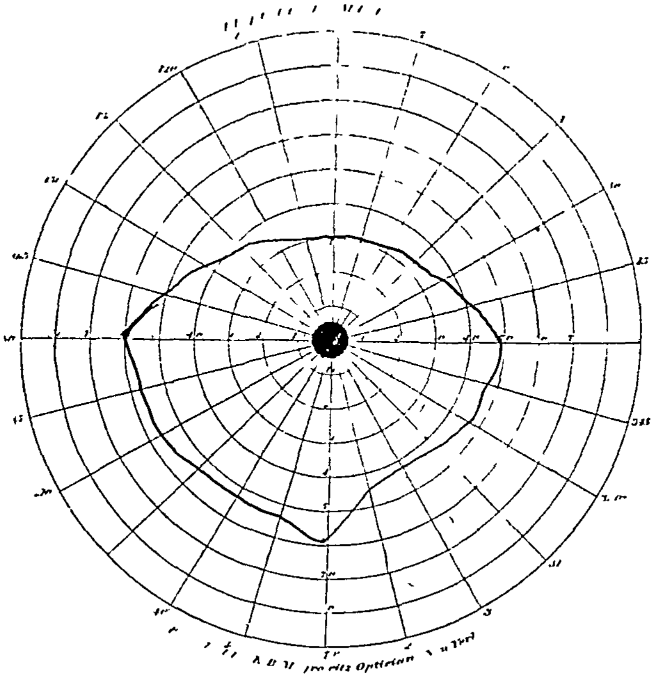
Case of Daisy Hubbard, Dec 1, 1897 Right



Case of Daisy Hubbard, Dec 1, 1897 Left



Case of Daisy Hubbard, Jan 10, 1898 Right



Case of Daisy Hubbard, Jan 10, 1898 Left

So much for the family history It is now 13 years since double iridectomies were done on C E B and she still retains her eyesight She has married and is the mother of four children, all boys, so that there is a good prospect of the disease being reported in still another generation at a later date

On Dec 1, 1897, Daisy H, a first cousin of C E B, their mothers being sisters, as above stated, appeared at my clinic at the Presbyterian Eye, Ear and Throat Charity Hospital Her sight was said to have been failing for two years Central vision was 20/30 each The fields were extremely contracted Pupils slightly dilated T + 1 Discs deeply cupped Eserin was instilled, and next day an iridectomy was done on the right eye A week later the same operation on the left January 10 there was a very great improvement in the fields, as shown in the accompanying diagrams, although at that time the central vision was not so good She left the hospital January 28

A letter received May 25 says she has improved greatly, that she has no trouble with the eyes, that they are very strong, that she can see well This interesting family is of French Huguenot stock, and are known in their county as the blind le Comptes There is a tradition that a black eyed woman, on account of some real or fancied wrong, cursed the family, and since that time all the dark eyed children have gone blind—those having blue eyes escaping It happens that the eyes of Daisy H are blue As far as I have been able to learn all the other glaucomatous eyes in this family are dark It would seem that the cases yield readily to treatment by iridectomy

DISCUSSION ON PAPERS OF DRS ELLIS AND HARLAN

Dr J L Thompson, Indianapolis—Acute glaucoma may be a primary or secondary affection and requires to be treated accordingly When there are no complications an iridectomy is preferable to all other modes of treatment, but I have seen cases where there is great chemosis of the conjunctiva with irido choroiditis or cyclitis, in which leeches and hot fomentation had to precede the operation which, after a few days, has been done with the happiest results I recall a case of acute glaucoma which accompanied retinitis albuminurica This also was relieved by the above methods and eventually passed off, but the patient died about four weeks later of Bright's disease

True hereditary glaucoma I have met with but once This occurred in a girl 11 years old, whose father had undergone extensive operations for caries and necrosis of the parietal bones of specific origin The child had the characteristic Hutchinson's teeth She had suffered from chronic glaucoma for over six months before I saw her The optic discs were very much cupped and the veins pulsating Eserin was used for a few weeks, but she became worse, tension +2 with vision below $^{2}/_{100}$ I made an iridectomy upon each eye which was followed on the fourth day by a hemorrhage into the left anterior chamber, and on the sixth by the same in the right anterior chamber These hemorrhages recurred several times inside of three weeks, which very much alarmed me But she finally recovered with V $^{20}/_{100}$ in one eye and [illegible] in the other She has had no trouble since

Glaucoma and detachment of the retina —Three months ago an attorney at law, aged 30 years, consulted me on account of his right eye, which became blind suddenly in childhood, but which gave him no trouble until a few months ago, when it caused a dull aching about the brow and temple I found an extensive detachment of the retina about the lower outer and inner parts of the disc, with a portion upward which was not detached This portion showed several pigmentary patches along the sides of the branches of the retinal vessels Tension +3, vision, right eye 0, left eye [illegible] I gave him a weak eserin solution and advised him to call on me again, which he has not yet done

We are still on a sea of doubt as to the cause of this hardening of the globe We have been inclined of late to lay too much stress upon the iritic angle and the spaces of Fontana Many of us have met with cases in which the anterior chamber has become unusually deep after cataract operations, and still the hardness of the eyeball has gone on increasing until sight has been destroyed I have met with one case of congenital absence of the iris and yet the eye was lost from glaucoma Iridectomy is still the most reliable remedy in a majority of cases, and still we have to deal with some chronic cases in which contraindications to operative interference obtain In many of these I have saved the sight for years by eserin in very weak solution and by massage of the eyeball Just how an iridectomy benefits a patient we know no more than we did when its illustrious originator wrote concerning it His last words on the subject apply to this day just as well as then Said he "No progress of importance has been made in respect to the theory of the operation, notwithstanding many attempts Old hypotheses are usually dragged forth, little as they avail for the explanation of existing facts The unhappiest of all, the one referring the effect simply to the wound of the ocular capsule is periodically brought forth, decked in some new formula and recommended for adoption Fortunately for our patients, practice advances independently on the foundation of empiric principles No doubt some day a satisfactory theory will be found, but in the meantime we must not be led away by transient hypotheses "

Dr Geo M Gould, Philadelphia—I wish to give my experience with one of several cases of glaucoma that may be instructive to some, for it certainly was to me An old Quaker lady came to me three years ago, after having had one eye operated upon for glaucoma, and the operation having been a failure in that the iris was almost completely torn from its attachment The pain had been lessened, but the tension, +2, remains until this day At the time she visited me the other eye had become quite hard and she was much frightened Her experience had been so sad with the operation that she refused to consider another, nor would she listen to anything like enucleation of the bad eye At that time I had also been trying massage, as Dr Thompson speaks of, and instructed her how to carry it out—for I believe the success of the treatment depends largely upon the delicacy of touch of the patient Despite the bad outlook in this case she now has perfect vision in that eye Massage has to be kept up at intervals according to the degree of tension of the globe, which shows a constant tendency to harden

Dr J O McReynolds, Dallas—About five years ago a patient came under my observation who had been operated upon for glaucoma two months previously The operation was an iridectomy and the eye was lost with subsequent development of very intense inflammation of the eye and it became necessary to enucleate She got along very well, but had repeated attacks of glaucoma in the other eye Just as has been the result in Dr Gould's case, she now has perfect vision and the treatment I employed has been massage and the repeated instillation of small doses of hydrochlorate of pilocarpin, combined with appropriate internal medication She has become so skillful in the detection of the early symptoms that she can make a diagnosis of its approach and she will carry on the massage and instillation of the pilocarpin until the tension comes down to normal One other feature I wish to mention is with regard to some of the exciting causes of glaucoma A patient was brought to me some time ago completely blind in both eyes as the result of glaucoma. He had lost one with glaucoma and after several months he went to an oculist fo-the purpose of having a pterygium removed from the good eye The operation was done and within two hours an acute, fulminating glaucoma developed in that eye, resulting in complete loss of vision I wish to bring out the point of danger in making any kind of an operation upon an eye that is predisposed to glaucoma It may have occurred in this case from the cocain, the operation, or the mental impression produced upon the patient, which I am quite sure has much influence in these cases

Dr Holmes—I would like to ask Dr Gould how often he advises the massage?

Dr Gould—Just as often as the tension goes above normal The manner of massage is, in my estimation, of importance, that is, the rubbing must be very slow and clear around the outer edge of the eye You can make great pressure if you will only go slowly and make no quick movements

Dr J E Minney, Topeka—I was recently called to a case of glaucoma where I desired to do an iridectomy, but they refused I inquired into the history of the case and ordered quinin The homeopathic physician who was in attendance said that he had put the patient on quinin and that he was giving five grains every four hours This treatment was continued and the patient was cured It was a case of malarial glaucoma I never thought so much about glaucoma until two years ago, when the pastor of a little church in Kansas was stricken with total blindness He called for the family physician because of the pain, and the physician injected morphin, which gave temporary relief He came to me in April, two months later, with the right lens dislocated into the anterior chamber, high tension and much pain The eye was enucleated, and he did well He returned to his charge, but six months later I had to remove the other eye It is the saddest case that ever came under my observation I think if those who are teaching medical students can only teach them two things, that is, to recognize iritis and glaucoma, they will be amply repaid

Dr C D Wescott, Chicago—*I would like to ask Dr* Gould, or others who have used massage, if they succeed in preserving the fields as well as the vision in these cases? I have had a patient under treatment for two years whose vision has remained 20/30, and whose tension is kept down, but the field has gone on contracting

Dr Gould—The field in the several cases I have had, and especially the one I referred to, remains normal, but I have only tested her with the finger for the past year

Dr Thompson—Some of my patients, in spite of the massage, have gone blind, but so have some of my iridectomy cases A great many cases have been benefited and the field has not contracted, but in spite of any treatment you will have some of the patients go blind

---

THE FIELD OF BINOCULAR FIXATION OR THE HOME OF THE GUIDING SENSATION OF THE RETINA

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo June 7-10 1898

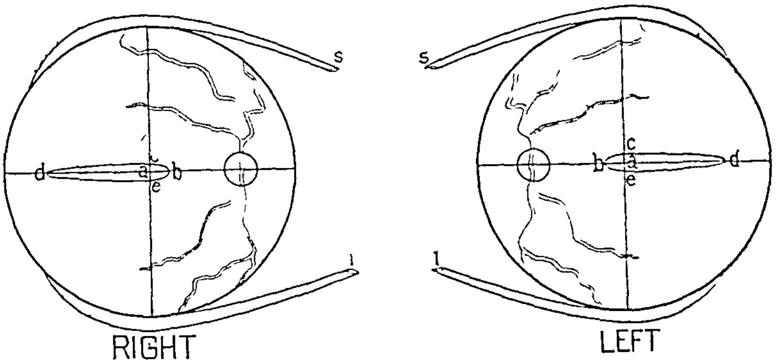
BY G C SAVAGE, M D
PROFESSOR OF OPHTHALMOLOGY IN MEDICAL DEPARTMENT VANDERBILT UNIVERSITY
NASHVILLE, TENN

A private letter from Dr Francis Valk of New York has led me into a further study of the guiding sensation of the retina In my book "New Truths in Ophthalmology," I have emphasized its importance as master of the extrinsic and intrinsic eye muscles, but it seems to me now that I did not place enough emphasis on it The part of Dr Valk's letter which has led me to undertake this communication is as follows "I have been reading your book lately and have been very much pleased with the work, but as I have read it a question has come into my mind that I want to ask you about I note that in your chapter on Accommodation and Convergence, you lay great stress and importance on the guiding sensation of the eyes, and there I agree with you, but if this function is so important, and I believe it is, then may I ask Of what value is any test for the power or balance of the ocular muscles that deprives the eyes of this most important function? In my own mind I am convinced that we must treat our cases of muscular difficulties according to nature's demands on the eyes, and we must not deprive the eyes of their most important function to understand their balance"

For many years I have taught my classes in the Medical Department of Vanderbilt University that, if we had but one eye, there would be no need for the extrinsic ocular muscles, that all of these muscles exist that there may be binocular single vision In simplifying the study of these extrinsic ocular muscles I teach that the recti, in the final results of their action are concerned only with the visual axes, that the superior and inferior recti, if acting in harmony, will keep these visual axes in the same plane, and that the lateral recti muscles will so control these axes as to make them intersect at the point of the object to be fixed

I believe further that, if these recti muscles could thus control the visual axes without effecting any other change, there would be no need for the oblique muscles in eyes not affected by oblique astigmatism Because of the fact that the inferior recti can not depress the eyes without, at the same time, effecting divergence above of the vertical meridians of the eyes, and the superior recti can not elevate the plane of the visual axes without, at the same time, converging above the vertical meridians, the necessity for the oblique muscles in all eyes for counteracting this torsion is at once made clear hence I have always taught that the oblique muscles exist for the purpose of keeping the naturally vertical meridians parallel, which I have termed the simple function of the obliques But in oblique astigmatism, with the meridians of best curvature converging or diverging above, the obliques are forced to perform their complicated function, which is to slightly converge or diverge the naturally vertical meridians Therefore the common function of all the extrinsic ocular muscles is the production of binocular single vision I believe these muscles are subject to one common master, which I have termed the guiding sensation of the retina I believe that the home of this guiding sensation in the retina can be outlined, and that within this area the guiding sensation, in a normal condition of the ocular muscles, has the complete mastery of them all I believe its throne to be the fovea centralis of the yellow spot of Soemering, and that its scepter sways over an area of the retina somewhat of the shape outlined in the accompanying cut

An image displaced 4 degrees to the nasal side of the macula by means of an 8 degree prism marks the inner boundary of this area, and, that vision may not be doubled, the guiding sensation commands the external rectus to abduct the eye so that the macula may be brought under the displaced image An image displaced to the temporal side of the macula 15 to 20 degrees, by means of a prism of 30 or 40 degrees, practically marks, on the horizontal retinal meridian, the temporal limit of this area To prevent double vision the guiding sensation can command, through the brain that the eye be abducted so as to bring the macula under the displaced image Likewise a displacement of an image on the line of the vertical retinal meridian 1½ degrees above or below the macula by means of a 3 degree prism, base up and down respectively would mark the upper and lower boundaries, on this meridian, of the retinal space constituting the domain of the guiding sensation To overcome the diplopia the guiding sensation only has to call into activity the muscles that will depress and elevate the eye Beginning at the nasal limit, *b*, a line drawn through the upper limit, *c*, thence through the outer limit, *d*, thence through the lower limit, *e*, thence back to the inner limit, *b*, encloses this retinal space An image displaced anywhere within this space in one eye, without any displacement in the other, can be fused with the non displaced image in the fellow eye at the command of the guiding sensation, the proper muscle always responding to the call Images displaced without this area can not be fused and no attempt is made at fusion, the guiding sensation having learned that its commands under such a condition will not be obeyed, or that it has no existence without this area It remains, nevertheless, a fact, that some eyes with abnormal condition have a smaller retinal area for the effective work of the guiding sensation, while in others, in which the extrinsic muscles are of more than what is considered normal strength, this area is larger Therefore it may be stated that in individual cases of heterophoria, this area will have its own shape, differing from that represented in the cut The drawing is intended to represent eyes whose abduction is 8 degrees, whose sursum and deorsum duction is 3 and whose adduction is from 30 to 40 degrees Between the lines, it may be stated here, that the diplopia which would be effected by a torsion of the eyes by the superior and inferior recti muscles, and the diplopia caused by oblique astigmatism, are each counteracted by the oblique muscles in obedience to a command from the guiding sensation



If this teaching as to the guiding sensation be true, what should constitute the methods of examination to determine the condition of the extrinsic eye muscles? It should be granted in the beginning that if there is orthophoria of all of these muscles the visual axes and the vertical meridians will bear the correct relationship to each other although the vision of one eye may be excluded by means of an opaque disc interposed No test for heterophoria can be fully relied upon, unless the displaced image in one eye is thrown entirely without the retinal area occupied by the guiding sensation for the eye under test should be taken wholly from under the control of the guiding sensation that the eye muscles might place the eye in the position of equal tension of all of the eye muscles, which means the position of rest There should be no displacement of image in the other eye[1] At once it would appear that the test by means of Maddox' rod could not be the best, for, in some part, the streak of light must invade the domain of the guiding sensation, necessitating some sort of effort on the part of the guiding sensation to effect the fusion of some part of the false image with the true For lateral heterophoria it would seem that a prism sufficiently strong to throw the displaced image entirely beyond, either above or below, the outlined area would be a *sine qua non* This would take, unquestionably the lateral muscles from under the control of the guiding sensation when the eye under test would swing itself into a position of equal tension of the externus and internus, thus causing the displaced image to stand to the right or to the left of the vertical plane of the true object The distance should be measured by prisms and that measurement would show the quantity of the lateral error, whether esophoria or exophoria Likewise, in testing for vertical heterophoria the image in one eye should be displaced to the nasal side of the macula, entirely beyond the retinal area under the control of the guiding sensation, when the eye, no longer under the control of the guiding sensation, would be elevated or depressed so as to give equal tension to the two vertically acting muscles The measurement of the elevation or depression should be taken in the usual way by means of prisms, and thus could be reached a correct understanding as to the quantity of the hyperopia or cataphoria of that eye

Objection to the double prism test would appear to be that one of the displaced images might fall within the retinal area of the guiding sensation and hence might lead to some error, but if the prisms are sufficiently strong both images can be thrown so far outside of this area as to make the test perfectly reliable

After having made the test for ascertaining the balance or imbalance of the eye muscles the intrinsic power of the recti muscles should always be taken By this it is meant that prism after prism should be used up to the point where fusion is no longer possible If a case has been found to be orthophoric and the abduction is 8 degrees, and the sursum and deorsum duction each 3 degrees, no condition could be more desirable This test would show that within the area under control of the guiding sensation, images can be easily fused by means of obedience on the part of the extrinsic muscles to the command of the guiding sensation Again, suppose that a case has been found to be exophoric and the abduction is only 8 degrees, or less, there is at once a clear indication for doing nothing at all to the external rectus muscle of either eye, but the attention, in such a case, should be turned to the interni, and the condition should be corrected either by exercise of these muscles or by shortening one or both of them

---

[1] The author has just now (September 20) perfected a phorometer on this principle

While the phorometer will always show the kind of heterophoria with which we have to deal, the duction test should always be relied upon as a correct guide in our efforts to bring relief

---

DYNAMICS OF THE EXTRINSIC OCULAR MUSCLES

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo, June 7-10 1898

BY FLAVEL B TIFFANY, M D
KANSAS CITY MO

Some years ago, when I became especially interested in the subject of the dynamics of the extrinsic ocular muscles, I read and reread the chapters on this subject As the subject to me at that time was abstruse and puzzling I tested repeatedly the strength of the ocular muscles in my own case, and as I could only get a fractional amount of prism dynamics compared with that given in the books I concluded that mine was an exceptional case, that the strength of my extrinsic ocular muscles was greatly below the normal, but when I began to test some of my patients and found that their abduction as a rule only amounted to 6 or 8 degrees, while the adduction rarely exceeded 20 or 30 degrees, which was much less than was stated in the text-books, I began to think that there was some mistake Either I had not thoroughly comprehended the subject and had used different methods or else the statements in the books were misleading But it was not until Dr J M Banister, major and surgeon U S A, read his paper that I was fully persuaded to make a more careful search in the subject

Last winter I examined 100 medical students (seniors) who were fully impressed with the importance of giving eqact answers that the real conditions might be obtained The examinations were carefully made with square prisms, Stephens' phorometer, Maddox rod and double prism test My associate, Dr George E Bellows, assisted me in making the tests and compiled the tables following

POWER OF ABDUCTION

No of cases	1	1	18	20	32	5	14	2	2	1	1	1	1	1=100
No of degrees	0	3	4	5	6	7	8	9	11	12	13	14	15	18

Unusual cases as regards relative powers

A—Abduction greater than adduction

Case, No	Add	Abd	Condition
51	8°	13°	Exophoria
35	6°	8°	
41	6°	12°	
65	8°	11°	
70	5°	7°	
81	6°	8°	

B—Abduction equal or nearly equal to adduction

Case No	Add	Abd	Condition
6	6°	6°	Exophoria
44	6°	4°	Orthophoria
52	10°	8°	Exophoria 8°
77	6°	6°	Exophoria
79	6°	6°	Orthophoria
94	8°	8°	Exophoria

Average power of adduction, 19° average power of abduction 6 26°, average power of sursumduction 2 45° average power of deorsumduction 2 16°

POWER OF ADDUCTION

10 degrees and under	17 cases
10 to 20 degrees	51 cases
20 to 30 degrees	22 cases
30 to 40 degrees	6 cases
50 degrees and over	4 cases

In making the tests I sought the power of abduction, adduction, sursumduction and deorsumduction I ascertained the exact condition of phoria, whether orthophoria, esophoria, exophoria, hyperphoria or cataphoria, especially for distant objects, or when the muscles were free from any static influence In testing at the reading distance orthophoria prevailed I took name, age, nationality, color of eyes and condition of refraction, and from the data obtained were formed the following tables

Several others might be made, but these will suffice to show that we have been in error as to the real normal strength of the extrinsic ocular muscles, that this power has been placed much too high, that the text books have been misleading and that the error in following editions should be corrected

[4] Could not discover trouble with right eye

[5] Could not find degree of esophoria

DISCUSSION ON PAPERS OF DRS SAVAGE AND TIFFANY

Dr G C **Savage**, Nashville—In reference to Dr Tiffany's statement that abduction has been placed too high (at 8 degrees), I want to state that I believe he is in error That we can have more or less abduction we all know, but where is the normal power? Is it at 1 degree or is it at 19 degrees? He did not tell us what was the condition of imbalance, whether esophoria or exophoria There must have been a considerable amount of exophoria in some of his cases How he can have a case with no converging power at all in a case not strabismic, and yet not be able to overcome an abducting prism of any extent, I do not know To my mind, the most complicated study in ophthalmology is a study of the ocular muscles, but I have reached this conclusion, that the study of adduction, per se, does not amount to a row of pins We can ignore it always, because it is such a variable thing But this is not true concerning abduction, sursumduction and deorsumduction I believe 8 degrees is the normal abduction power, and we are pretty well agreed that 3 degrees is practically normal for sursumduction and deorsumduction

Dr J O **McReynolds**, Dallas—I feel that the difference in results obtained by various observers will depend much upon the kind of instruments they employ Dr Tiffany, I understand, has used square prisms, and I believe that method will not give as accurate results as may be obtained with one of the various phorometers The phorometer I employ is an extension of the idea advanced by Dr Risley I have had one made in which I have an arrangement with the ordinary appliances of the Stevens phorometer, spirit level, etc , and two cells containing the Risley prisms, so that I can get any degree of prismatic effect in any direction, and by increments that are infinitesimal It enables me to get the abduction, adduction, etc , as well as the balance I feel sure that before any operation can be made we ought to be in possession of all these facts as well as the constitutional condition of the patient

Dr B **Alex Randall**, Philadelphia—I would like to enter a word of protest as to the matter of making muscle tests, not only to the points brought forward by Dr McReynolds as to the constitutional condition and the instrumental difficulties, but to insist that we shall begin by understanding the fundamental condition, which is the refraction of the eye All tests of the muscles depend, primarily, upon the refraction, and with all due respect to Dr Tiffany or any other man, when I hear of hosts of cases that are emmetropic, I am skeptical as to all the rest I must say, as a result of my investigations, that true emmetropia is almost an unknown quantity, and the varying degrees of hypermetropia and other errors which are ignored in most of these cases, furnish the results and vitiate the conclusions drawn I have yet to see one of the cases (of which Dr Noyes has reported so many) of insufficiency of the sternal muscle I have invariably resolved them into cases of hypermetropic convergence It is impossible, sometimes, to do that at first under a mydriatic, no matter which one is chosen, or how vigorously it is employed, but if it be repeated long enough we will get true refraction, and until that is done, and too often it is not even attempted, or at best, normal vision or lack of palpably magnified ametropia is assumed to show emmetropia, we can not get the muscle balance

Dr Geo M **Gould**, Philadelphia—I want to add one word of hearty commendation to what Dr Randall has said I have made all these tests for eight years, and as a result of that experience, and of gymnastic exercises, I protest against this remark of our friend Dr Savage, that the fact of adduction may be left out of consideration To me, the question resolves itself into this What is the proportion between abduction and adduction? and, furthermore, the existence of symptoms I first correct all ametropia, and that correction is modified by the proportion between abduction and adduction, and after that if the symptoms do not disappear it is time enough to work upon the muscles As to the method, what shall it be? I never, as yet, have had a case of exophoria in which I was not able to develop enough adduction power by gymnastics not only to relieve all symptoms, but to get such power of the eye that there is no difficulty in work The proportion should be 1 to 3 or 4 I try to run the adduction in a case of say [illegible] degrees of exophoria to start with, and [illegible] of add[illegible] up to 60, 70 or 80 degrees, and, if [illegible] do n[illegible]

100 or more degrees, until the eyes positively turn in, and there is sufficient power to do away with all discomfort Esophoria I do nothing with; and I have never seen any one that could do anything with it I have seen cases operated upon without the least result I have one patient, a minister, with 20 degrees esophoria yet he is working every day without difficulty, when his ametropia is corrected

Dr J L Thompson, Indianapolis—I think it is the rarest thing to find an orthophoric individual, and I think the normal condition of the muscles for distance is 1 or 2 degrees of esophoria I believe that is the natural condition of man, just as it is natural for the flexor tendons of the hands to be under some tension

Dr Sampson—This question is of great scientific interest But to the most of us that practice medicine the question is, what can we do for the patient? The more I read about it and try to apply it, the more apparent it is that the question of ductions and phorias has not yet been placed on a distinctly scientific and practical basis

The methods of determining muscle balance are certainly at fault, and any one of them implicitly depended on will not infrequently lead one into error Speaking of converging power, insufficient adduction is certainly responsible for much of the trouble with which we have to deal I have noticed it particularly among school teachers of the female sex, they frequently have exophoria, the converging power not exceeding 10 degrees, while their work requires extensive use of the converging muscles We frequently find them run down in general health and the whole muscular system short on endurance They seem incapable of sustained muscular effort, and the converging eye muscles participate in the disability In many of these cases examination of the urine will show markedly diminished excretion of total solids, and it is surprising to see the effect of copious water drinking and giving attention to the constipation which usually coexists, for as the general health improves, the power of adduction increases and ocular discomfort subsides, often without the use of any of the special means invented for cultivating ocular muscles

The inclusion of patients of this class in the accumulation of statistics would manifestly lead to erroneous conclusions, and from what I have been able to observe it appears to me that any individual presenting muscle anomalies would be pretty thoroughly untangled before his phoria or faulty duction would be counted as an intrinsically local disturbance

Dr Tiffany—The object of this paper was not to discuss the condition of heterophoria, but to establish a normal condition of the muscles, and that I think we have done by an examination of the 100 cases given As I have said they correspond with the results reported by Dr Bannister

RECENT EXPERIENCE WITH ADVANCEMENT OF THE RECTI MUSCLES

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10 1898

BY C H BEARD, M D
CHICAGO ILL

To review the several ingenious theories as to the causes of strabismus, to endeavor to dispose of the intricate and subtle anatomic and physiologic problems pertaining to the imperfectly known branch of ophthalmology, to discuss all the pros and cons concerning the relative merits of tenotomy and advancement, as well as of the methods other than surgical for the treatment of the affection, would be highly agreeable, such, however is not my present intention I have, from time to time, in the past stated my convictions in these matters, and shall on occasion, continue so to do, always striving meanwhile for something better yet, to offer in lieu thereof, not disdaining to iterate and reiterate in accordance with such poor light as we possess for I believe the theme demands it The subject of this paper was suggested to me by the worthy chairman of this Section, and in order to make my report systematic, I have tabulated from my private records about all of the strabismus cases that have come for consultation to my office during the past six years

I have chosen to make the report from private practice because the statistics there are fuller and more available, though I hope ere long to give a compendium of results in this line, referable to the hospital and the dispensary, where the great bulk of my work in this department has been done I shall attempt a partial summary I found that out of the total number of cases that came for consultation in that time 214, or about 4 per cent were cases of strabismus These do not include paralytic nor latent squint Of the 215 cases 142 were of the convergent variety, 70 were divergent and two were mixed, i e, there was convergent strabismus in near vision, and divergence for distance Six of the cases of divergence were secondary or operative ones

Of the 142 convergence cases, in 74 the left was the squinting eye, 17 alternated, and in 51 the right eye turned In 18 the squint was intermittent or periodic when first seen

Of the 70 cases of divergence, in 29 the left eye deviated, in 15 the eyes alternated, and in 26 the right was the squinting eye Ten of these were intermittent I may remark in passing that in the beginning most of them are intermittent

Of the 142 cases of convergent strabismus the refraction of both eyes was hyperopic in 114, both myopic in 6, antimetropic in 2, and emmetropic (or practically so) in 20

Of the 70 cases of divergent strabismus the refraction of both eyes was hyperopic in 38, myopic in 16, mixed in 2, antimetropic in 3 and emmetropic in 11 Deducting the six secondary cases, gives us exactly twice as many cases of divergent strabismus associated with hyperopia as with myopia, a significant point in studying the causes of strabismus

Of the 114 cases of convergent strabismus with hyperopia of both eyes the error amounted to three or more dioptrics in 63 Of the 6 cases of convergence with myopia the latter was three or more dioptrics in 4

Of the 38 cases of divergent strabismus, associated with hyperopia of both eyes, the degree of the hyperopia was three or more dioptrics in 9 cases Of the 15 cases of divergent strabismus with myopia in both eyes it was three or more dioptrics in 8

Of the 214 strabic patients 78 were under 15 years of age, 101 between 15 and 30 years, and 35 were over 30 There were 129 females and 85 males The angle of the squint, or, rather, the angle of the optic axis of the squinting eye to the right optic axis of the working eye ranged from 12 to 65 degrees

Of the 214 cases 158 received treatment in some form In many instances this began and ended with the fitting of a pair of glasses Fifty-six were not treated at all, having come merely for examination and consultation Out of the 158 patients treated 70 had one or both muscles advanced, the second muscle

---

Note —Owing to the limited time, this paper was read by title and at the request of the President of the Section, the allotted time was occupied by its author in describing his advancement operation The accompanying discussion, therefore, has reference to said description having been brought forward in about 12 per cent of the cases The operation was for convergent strabismus in 50 of the cases, and for the divergent form in 20, or in other words, of 81 advancements on these 70 patients 57 were of the externus and 24 of the internus The inferior rectus was advanced once after correction of the lateral deformity Of all the advancements only three were for alternating strabismus, two convergent and one divergent alternating

Of the 70 patients to have their strabismus corrected by advancement, just one-half the number had a high degree of amblyopia in the squinting eye, with fair to good vision in the fixing eye Thirteen had 20/20 in both eyes Thirteen had 20/30, and ranged from 20/30 to 20/50 This is the corrected vision In the rest (2) the sight was not determined The vast majority of patients who had advancement ranged in age from 15 to 30 years, that period of life during which the duty of looking one's best is most imperative

In 32 cases the strabismus yielded to atropin and glasses, in nine more cases to glasses together with persistent and systematic orthoptic training with prisms, the stereoscope, etc The corrected visual acuity in the 41 cases whose squint was righted by other than surgical means, amounted for both eyes in 18 instances to 20/20, in 15 to 20/30, and in 1 to 20/50 One eye was highly amblyopic in 5, and in 3 the sight was not definitely ascertained

Thus, out of 158 cases treated in some measure a cure was accomplished in 111, leaving 47 who are either reporting from time to time or have wandered off Were I not so strongly opposed to the operation of tenotomy, excepting for its effect in combination with that of advancement, I might not now have the satisfaction of reporting these 41 cures of strabismus accomplished without surgical interference, for I believe that the very ease and facility with which that operation is performed, and the comparatively little inconvenience to the patient which it occasions, has led to its abuse We should not lose sight of the fact that surgery is only one of the means toward the end in question

I find that, as time goes on, I make relatively fewer advancements on the other eye Not that I have changed my views as to the beneficial effects of double advancement, but chiefly because of the difficulties or the obstacles in the way of bringing the patient to submit to the second operation I have, therefore, in the more recent operations, been striving for greater effect at once

Donders was unquestionably right in asserting that strabismus is essentially a binocular affection The tests of motility and fixation in a vast majority of the cases will show limitation in the direction opposite to that of the squint in both eyes Hence, were it practicable always to have one's choice in the matter, I believe it would be better to make a moderate advancement of the corresponding muscle in each eye, than to confine all to one It is true, in one sense, that what we do toward changing the position of one eye is done also to the other, so that while it is feasible to correct the strabismus by operating on only one eye the squinting eye, for instance, in the constant monolateral form and on the worse eye, if there be a difference, in the alternating variety, I do not, however, regard the procedure as strictly scientific The increased tension put upon a muscle by a properly gauged advancement is a means of putting new life and vigor into it, but there is a limit, beyond which the stretching of the muscle should not be carried Even granting that we right the deformity by a single operation, and without drawing up the muscle too tightly, the improved tone of the operated muscle is only in a measure imparted to its fellow of the opposite eye, and the result is somewhat one sided after all For these reasons, when the faulty muscle of each is proven to be markedly inefficient, I give the patient plainly to understand that two advancements will be necessary It will be observed that it is not so much the degree of the squint which is taken as the criterion for the extent of the advancement, as is the strength, or weakness, if you choose, of the offending recti, some of the very slight deviations often requiring a most decided moving forward of the tendon Again, it is not uncommon to find that the eye which habitually squints is possessed of the better muscular system of the two Under such conditions, the vision being equally good in both eyes, and only one operation being contemplated, it is good practice to make the advancement on the working eye I would deem it advisable, always, where exists a pronounced difference in the strength of the faulty muscles, to allow this, and not the deviation, to determine which eye should be operated upon, were it not for the fact that the squinting eye is so often but poorly endowed with vision It is the dread of that possible mischance In careful hands there is no safer operation made than this, yet eyes have been lost from slighter things, and one can not ignore the possibility, be it ever so remote Especially is this applicable in dispensary practice, where many irresponsible patients may be expected to go into homes and surroundings which are not calculated to favor the traditional "uneventful recovery,' and to report back to the surgeon at their own sweet will

In all of my experience, however, in the management of several hundred advancements on hospital and dispensary patients, I have had to contend with but one eye that gave any cause for uneasiness It was that of a young man treated at the North Star Dispensary, who reported on the fourth day after the operation with suppurative tenonitis, beginning at the site of the advancement He was put at once into the hospital, the thread removed, and by vigorous measures the process was arrested before anything really serious occurred It will be observed that this operation means advancement in the true sense of the word in that it gives a new insertion for the tendon, nearer to the cornea than the original one Many of the so called advancements consist merely of a shortening, inasmuch as they do not move the insertion at all Even though a small section of the tendon may be removed, the quality of the operation is not altered Often, in the early stages of healing, the tendon can be clearly seen firmly adhering to the globe forward of its former place of attachment But to attempt to regulate to the millimeter the exact point at which this union of the tendon with the globe shall occur, as some operators assume to do, is surely an illusion By exercising care in obtaining firm holds for the thread, both in the tendon and in the places of anchorage above and below the cornea, we may be confident of a positive and permanent advancement, but gauge it to a mathematical nicety w[illegible] not As Landolt has neatly said, "Nature d[illegible] us if we make [illegible] ment help, neglect it [illegible] allow[illegible] ping back [illegible] er-c

---

[1] I removed congenital capsular cataract from both eyes in this case when the child was less than 2 years of age

[2] There is paresis of the accommodations, requiring +3 for near vision These glasses prevent squint

[3] Advt right externus, curbed tenotomy right internus advt (later) of right inferior rectus, result perfect

[4] Advt right externus tenotomy all outer portion of right superior rectus

[5] After using drops one month eyes became straight and have remained so for five years

[6] Extracted cataract from right eye needled left pupillary membrane

In conclusion, I would add that the more I study the anomalies of the ocular muscles, the more I see and the more I do, the stronger becomes my conviction that muscular advancement is the only operation —not the only *treatment*—but the only operation, not only for all forms of strabismus, but also for the strabic tendencies De Wecker of Paris, in a recent magnificent paper on the results of strabismus operations (Annals d'Oculistique, January, 1898), recommends advancement whenever binocular single vision is the end in view, *and tenotomy, or tenotomy and advancement* when the ultimate aim is a cosmetic result A stronger endorsement than this of advancement as the best procedure in *all* cases could hardly be conceived

ADDITIONAL NOTES ON EMPLOYMENT OF ABSORBABLE SUTURES IN THE OPERATION OF LOOPING THE TENDONS OF OCULAR MUSCLES

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10 1898

BY JOHN O McREYNOLDS, B Sc , M D
DALLAS, TEXAS

In my original paper on this subject before this Association in 1897, I briefly referred to a method of employing kangaroo tendon in the operation of shortening the ocular muscles, but additional experience has taught me the importance of certain modifications, which I will attempt to present for your consideration today And I shall feel more than amply rewarded for the labor of this pleasant task, if the members present will kindly contribute their suggestions from their wealth of vast and varied experience

In the first place, I should like to say that the kind of suture material and also the method employed should vary according to the amount of correction desired Speaking in general terms, I would consider that for the different forms of heterophoria of moderate degree, the catgut suture will supply the requirements and should be preferred because of the fact that it is practically absorbed within three or four days and will involve the minimum amount of reaction But when this material is used the heterophoria should be over-corrected in order to allow for relaxation of the sutures and the stretching of the newly formed adhesions In cases of extreme heterophoria and in heterotropia, kangaroo tendon offers the most reliable results, because of the fact that it does not become absorbed for two or three weeks and does not weaken rapidly from contact with the tissues, and hence will maintain the structures in the desired apposition until firmer adhesions have formed And when this kind of suture material is used, we should secure at the time an amount of over correction proportionate to the tension placed upon the sutures

With regard to the method of operating, I would say for small degrees of heterophoria employ this method with broad fixation forceps provided with teeth sufficiently long and sharp to engage all the structures down to the sclera, grasp the conjunctiva capsule of Tenon and ocular tendon in such a way as to produce a vertical loop of the ocular tendon Then fix this loop by a single suture passing through it horizontally If it is desired that the thread should sink beneath the conjunctiva, a slight incision through this membrane will allow this suture to bury itself in the tissues within its grasp while the conjunctiva closes above it

For high degrees of heterophoria and moderate degrees of heterotropia, I would advise the following Make an incision along the border of the tendon penetrating the capsule of Tenon Then with strabismus hooks lift the tendon gently from the subjacent sclera Then take a thread armed at each end with a sharp, delicate needle, and introduce one needle beneath the tendon close to its scleral attachment, while the other needle is introduced beneath the tendon as far from its scleral attachment as possible Then carry each needle straight through the tendon, avoiding the conjunctiva, which is simply held aside with fixation forceps Then tie the free ends of the thread thus fixing the loop of the tendon, then bring together the conjunctiva and leave the loop to form adhesions and atrophy

Where the degree of deviation is very considerable it is well to precede the advancement of the weaker muscle by a tenotomy of the stronger one, and then the advancement can be made in accordance with the methods already described, or we may employ another plan, which has the advantages of great leverage upon the eyeball and at the same time less puckering of the tissues The procedure is as follows Along the border of the rectus make an incision through all the structures down to the sclera, then with strabismus hooks lift up the tendon gently from the adjacent sclera Introduce the two armed extremities of the thread beneath the muscle at points as remote as possible from the insertion of the tendon, one needle entering the muscle near its lower border and the other needle entering the muscle near its upper border These needles are carried from within outward through all the tissues till the conjunctiva is reached and then the needles are carried beneath the conjunctiva, one passing along the superior corneo conjunctival junction and the other passing along the inferior corneo conjunctival junction When the threads have reached the opposite side of the cornea from the tendon to be advanced the threads are made to approach each other, while the necessary traction is exerted by the tying of the threads, thus producing a decided rotation of the eyeball toward the tendon to be shortened The conjunctival wound can now be closed and the sutures left for absorption

In all these operations for muscle shortening the great advantages over the various tenotomies, graduated and complete, are the accuracy with which the adjustment can be made, the freedom from danger of over-correction and the fact that the process is one for making shorter the weaker muscle and not making weaker the shorter muscle in other words, the advantages are accuracy, safety and strength

DISCUSSION ON PAPERS OF DRS BEARD AND McREYNOLDS

Dr H V Würdemann of Milwaukee—Since Dr Beard first demonstrated this operation to me, probably about six years ago, I have used it somewhat extensively, at least more than any other form of advancement operation for heterophoria and for cases of strabismus in which a decided amount of reposition of the recti muscles is needed I have used it most satisfactorily in cases of strabismus of more than 15 degrees For cases less than this, or for heterophoria I prefer one of the minor forms of advan [illegible] described and others I do not [illegible] the tend [illegible] described by Beard, [illegible] of o [illegible] the tendon over the other gives us a more secure hold, as in the healing process we get agglutination, and the little thickening is absorbed sooner or later, so it is of no particular consequence Immediately after the operation is finished we frequently find that the cornea is practically covered by a fold of conjunctiva, but that is an advantage, for it lies under the stitch and is a protection to the cornea After seven or eight days the reaction entirely passes away, sometimes sooner It is advisable to use braided silk for the sutures I object to the use of absorbable sutures in any form of advancement on account of the tendency for relaxation We frequently find by this method, as well as by others, an over effect of apparently 5, 10, or 15 degrees, but the next day, if the suture has slipped at all, we may have an under effect, so I think it more desirable to have a stitch that will hold I believe it is advisable to leave a loop in the stitch during the operation in order to pass the suture through, and find it more convenient than having to pick up the loop afterward, and I wish to lay stress upon the necessity for the needles being very sharp We must get a good hold on the sclera

Dr Melville Black—I would like to demonstrate on the blackboard a little operation of my own that resembles this one of Dr Beard's very closely A curved needle is threaded with No 5 iron dyed silk and the two ends tied into a hard knot The needle is passed through the conjunctiva into the sclera for a good bite just below the cornea Before pulling the thread through up to the knot, the needle is passed back between the two strands of thread close to the knot and then pulled home You will observe that I now have a point of scleral fixation close to the cornea, and at the free end of the thread is the needle A similar procedure is now gone through with above the cornea You see that I now have two sutures similarly tied into the sclera at corresponding points above and below the cornea With a strong pair of mouse toothed forceps the belly of the muscle to be advanced is now raised, and with a pair of scissors the conjunctiva and underlying tissue are incised along the border of the muscle above and below A tenotomy hook is passed underneath the muscle and the forceps withdrawn One of the needles is passed through the muscle, or tendon, according to whether it is desired to do a strict advancement or a shortening I forgot to say that the needle is passed from below upward The thread is pulled about halfway home The other needle is now passed in a similar manner If it is desirable to do an advancement, the tendon is severed from its attachment If it is deemed best to shorten as well as advance, the needles have been passed through the muscle at an appropriate distance from the tendinous insertion, and the muscle should be severed about two millimeters or more from the needles, or rather the threads The tenotomy hook is now removed and the attached end of the muscle is grasped with forceps and severed from its attachment to the globe The conjunctiva should be removed at the point where it is desirable to pull up the muscle for re attachment Now comes the advantage to be gained by having performed the operation as described An assistant is not needed, because the operator can grasp with one hand the two threads, and with his other hand the globe is rotated in the desired direction with a pair of forceps When the eye is drawn into the desired position the two threads are tied over the muscle, and the operation is completed You will observe that there can be no torsion of the globe caused by one suture being shorter than the other, because there is enough play of the sutures in the muscle to overcome any such inequality The sutures are allowed to remain in position for five days, when, as you will observe, they are very easily removed This operation has proved universally satisfactory, both for advancement in heterophoria and for shortening and advancement in extreme cases of true squint I always perform the operation under cocain anesthesia, except in very young children, and find that it takes but little longer than simple tenotomy A wet bichlorid dressing is applied and the eye bandaged for twenty-four hours The patient experiences but little pain, and there is scarcely any reaction on the following day

Dr G C Savage—"Man wants but little here below, nor wants that little long," but we all want credit for any operation we may have devised Dr McReynolds will acknowledge that the operation he described was devised by me I have seen Dr Beard perform his operation and I want to say that I believe the operation is rather too severe for the effect to be accomplished I agree with him on this point, that in straightening the eyes it is better to do a partial tenotomy of the offending muscle and an advancement of the other, than to cut the muscle completely loose from the eyeball A partial tenotomy ought always to be done in squint, and the rest accomplished by advancement, and having done the partial tenotomy I think the Stevens advancement is the best operation to conclude with The reaction is slight and there is no torsion Of the two operations described here today I want to say that I believe Dr Black's is the simpler, secures the same effect and does not require a general anesthetic In any operation the less traumatism we produce in accomplishing our purpose, the less danger there is of infection Muscle shortening is applicable only in the heterophoria In heterotropia its effect is too little

Dr Beard—I used to tie the sutures in a bow knot at first, and it may be a good idea still, but I found it difficult to get the patients to come back and have the knot adjusted I came to the conclusion that it was not practicable and lately have not used it This is only one method of treating strabismus, and I have only used it in cases that would not yield to any other treatment As regards the degree of turning that one can get, that depends merely on where you place the suture, for you can get up to thirty or forty degrees with ease

Dr Kinney—Do you have any difficulty with torsion and do you both shorten and advance?

Dr Beard—One idea of this operation is to prevent torsion If the thread is properly inserted and there is no snarl, the muscle comes forward directly in line with its axis, and the tension on the thread is equal at every point In reply to Dr Savage, I would say that I never use a general anesthetic for operation, except in cases of little children or excessively timid adults

Dr McReynolds—One of the most important features, to my mind, was the employment of an absorbable suture instead of silk, because of the difficulty I found in getting the silk out of the loop This was almost as much of an operation as the original one I consider the kangaroo tendon the best because it is absorbed the more slowly In my experience I can secure as much correction as I desire, if I can get a hold as far back as I please, and if I want the maximum of correction I pass the suture clear around the cornea to the opposite side

A STORY OF CHICKAMAUGA

[PART II]

BY R STANSBURY SUTTON, M D
Major and Chief Surgeon U S V, Commanding Second Division First Army Corps Hospital at Chickamauga

There was a great deal of sickness at Chickamauga Park You would not expect to put 60,000 men in a camp seven miles square and keep them there all summer without sickness Furthermore, a large number, the great majority, were from northern climates and not only had they that to contend with, but their entire mode of living had been changed, and they were necessarily subjected to daily drill of about five hours, required to educate them to be soldiers In addition to this they had their camp duties to perform and their own necessities to look after, and it was but natural that some of them should become ill. Volunteer soldiers, without experience in camp life, great numbers of whom at home were unaccustomed to hard work and plain food, would naturally suffer some inconvenience. In every army there is an element which, if not restrained, will abuse themselves by drunkenness, vice and immorality, and this army has been no exception to other armies. There was considerable suffering by reason of these things. In this respect, however, at Knoxville, there has been a marked improvement. This element is being held down by a strong provost guard. Before our army entered Chickamauga Park—and 75,000 troops have been there—typhoid fever was prevailing, as stated, among the farmers living on the edge of this park; they supplied the camp, to the extent of their saleable articles, with milk and general farm products, and it is entirely probable that they introduced the infection. In time the camp became reinfected through the sinks and careless use of the grounds by soldiers. When the rains set in about July 17, the surface infection was washed into the creeks and streams, the soldiers resorted to the swollen streams for bathing and washing purposes, and this was doubtless another cause of the spreading of the disease. The flies were in the camps by myriads, and they carried on their wings, legs and bodies the typhoid germs from the sinks and elsewhere, over the camp, infecting the food and drink to a greater or less extent. Another source of infection was doubtless cases of typhoid imported by regiments coming from other places, but the disease did not assume alarming proportions until about August 10, after the rains had ceased. The water supply has been, by the public press, credited with a great deal of the disease in Chickamauga Park. This supply was from four sources. The springs outside of the park, from which the water was hauled by mule teams, were, I believe, sources of pure water, and from one of these I supplied the hospital, in which our mortality was 14 out of 984 patients. The second supply was by pipe line from Crawfish spring. In regard to the purity of this water there has been a dispute. The influent pipe was, until August 6, at least a mile below the spring, but after that date was carried up the river to a point near the spring, but after digesting all the causes of typhoid in the camp, I am disposed to give credence to those who have pronounced this water to have been pure. The third source was from drilled wells. Into them was dropped a tube with a pump attached, and the surface water reached and polluted that water, and it was impure. For a time some troops got water from these wells, but they were shut off by order of S. H. Hysell, Division Surgeon-Major. The form of typhoid fever prevailing was not always of a severe type. Hundreds of these cases were called cases of malarial poisoning. They went about in camp, unfitted for duty, growing thin and pale and eventually went to bed, or beginning to convalesce, got well, uncertain as to whether they had malarial fever or typhoid. Outside of typhoid fever and the results of indiscretion the troops were comparatively healthy, and cases of ordinary sickness did not exceed a reasonable expectancy in camp life. The medical staff of the army at Chickamauga were men of more than average ability, and I have never before seen a more enthusiastic devotion to duty than was evinced by them. As commanding officer of the second division hospital, I had seven commissioned officers. Six of these were medical directors. Major H. B. Bagley of Wheeling, W. Va. had charge of the surgical department, with Captain Dutton of Minneapolis as his colleague. Major P. J. Myers of Fostoria, O., had charge of one half of the medical wards, with Lieutenant Little, of Macon, Ga., for his colleague. Major Charlton of Indianapolis, with Lieutenant Nesbitt of Fairmont, W. Va. had charge of the other half. The devotion of these men to their respective duties is best told in the statement that of 984 patients on the hospital register, but fourteen died. The hospital averaged about two hundred and twenty-five patients and occupied within its site for all tentage about three acres of ground. The hospital corps after August 20, consisted of about one hundred and five men. Prior to this date it was as low as thirty-nine members. From this corps, nurses, cooks, clerks, guards, men for general utility work, keeping grounds clean, hauling water with mule teams, etc. were furnished. Lieutenant Cary, seventh officer, from Duluth, Minn., had charge of the commissary department, and proved to be an able officer. The rations furnished by the government were of good quality and abundant. In addition a liberal supply of fresh meats was furnished daily. We had three kitchens running constantly, with men cooks, as there was not a woman helper on the plant. The Red Cross Society, the National Relief Society, the Army and Navy League of Cincinnati and also the auxiliary Red Cross of Pittsburg funished me with large quantities of supplies, well adapted to the use of the sick. The latter were well supplied with pajamas, night shirts, slippers, towels, soap, jellies and jams. There are many things in the way of new drugs which the government does not furnish, and the division hospitals and general hospitals receive almost the entire attention of the societies mentioned. The regimental hospitals were left almost entirely without any of these things for their sick, whom they were expected to send into the division hospital promptly, but the latter was often so full that they could not receive them as rapidly as was expected, and consequently for this and other reasons there were at all times sick in the regimental hospitals. The Pittsburg Red Cross sent me $500 in cash, which I distributed largely among the chaplains of the various regiments, for the purchase of milk, butter, poultry and unfurnished drugs for the use of the sick detained in the regimental hospitals. When we take into consideration the fact that the government, in a remarkably short time, aggregated an enormous army of inexperienced and undisciplined soldiers and undertook its maintenance and its detailed care, any unprejudiced observer, with any prior army experience, must arrive at the conclusion that the government has done well. There were times when the supplies of lumber for tent floors and cots were difficult to procure quickly, and unless an emergency had existed requiring their immediate use the delay would not have been serious. Moreover, it is possible that some delay may have occurred in the delivery of these things from other causes than a scarcity of the articles. When you compare the condition of the soldiers in Chickamauga Park in 1898 and in 1863 and 1864, you are forced to the conclusion that the soldiers of 1898 had the best of it. Before I went into the service I wrote to Senator Quay saying that the troops o[illegible]t to be [illegible]ated and prepared for service in no[illegible] I ha[illegible] no reason to change that [illegible] tated that our Northern troops would naturally suffer more in a southern climate in camp life than Southern troops would, but the First Georgia volunteer infantry was a part of the second division and I received their sick at the division hospital They contributed a larger portion to the sick than any other regiment in the division The fact that they were acclimated was not sufficient to enable them to stand up to camp duties in their own State any better, nor as well, as their more sturdy brethren from the Northern States and I believe now that Southern troops should be drilled in Northern camps, in a summer season pending a campaign These observations apply only to the portion of the army at Chickamauga, and are not presented as the views of other officers, who may have looked at matters from another standpoint There has been an enormous amount of exaggeration in regard to the condition of affairs Of course there have been instances of seemingly unnecessary suffering, but I know of no instance which was followed by death or other serious consequences, and in an army without battle-wounds it is difficult to conceive how the hard conditions of war could prevail to any extent There were times when sick men were lying on the ground, which was dry and carefully cleaned, and they were under cover This was only temporary whereas in the Civil War it was a constant occurrence This time the rations were abundant, the delicacies more than enough, tents were always at hand On the night of September 8, a sudden cold wave swept over the camp at Knoxville The patients in the division hospital did not all have blankets enough, and the army supplies were not at hand, as the emergency was not expected At 9 P M two or three hours after the wave had struck the army, I had a wholesale merchant hunted up in Knoxville and with the money furnished by the Pittsburg Red Cross, I [illegible]rchased 100 double blankets and sent them up to [illegible]ajor Bagley, *then in charge, and some patients* were made more comfortable While it would have been well to have had an extra supply I can scarcely conceive of any negligence on the part of the government to meet an almost unprecedented cold snap at this season of the year in that climate

Where large bodies of troops are to be kept in one camp for a period beyond fifteen days, the government should provide crematories for the burning of all kitchen garbage and hospital refuse gathered daily The sinks for reception of stools should be deep, and so inclosed that the pit is perfectly dark A building of boards should be erected over the sink, proper seats with lids should be within it, and the entire building should be coated with several layers of a solution of lime, carbolic acid and formalin, and several gallons of the latter in 1 per cent, solution should be thrown into the sink daily A solution of formalin is superior for the disinfection of typhoid stools, and such stools should be disinfected in a sink designated to receive infected stools only

The lessons of the war are many and are not yet all revealed The country at large will profit by it, while individuals in many instances will reap sorrow and disappointment I would again suggest, as I have already done, that inoculation for typhoid fever be tried on all troops going to Cuba excepting in cases where the soldier has had the disease within a few years Three soldiers companions, left Chickamauga for Porto Rico One, convalescent from typhoid, bemoans his hard luck two perfectly well were jubilant On the voyage out the invalid recovered, grew strong and returned well The other two developed typhoid fever and died in Porto Rico Here is, in this illustration, the sequel of the whole question of immunity, its importance, and its possibility Surely a serum can be prepared for the attempt

COLPOPERINEORRHAPHY AND THE STRUCTURES INVOLVED

DEDICATED TO DR THOMAS ADDIS EMMET AND MR LAWSON TAIT
IN RECOGNITION OF THEIR LABORS IN THE SURGERY
OF THE PERINEUM

BY BYRON ROBINSON, B S, M D
CHICAGO ILL

Continued from page 788

GENERAL CONCLUSIONS

1 To cure sacropubic hernia (uterine prolapse), perform amputation of the (sharp) cervix, anterior colporrhaphy, Tait's flap perineorrhaphy

2 The amputation of the cervix is for the purpose of removing the sharp cervical point directing the cervix backward, restoring the uterus to normal position

3 The anterior colporrhaphy is for the purpose of narrowing the vagina, elevating the bladder, directing the cervix backward and the fundus forward

4 The Tait flap perineorrhaphy is for the purpose of restoring the perineum restoring the obliquity of the genital canal restoring such a central floor as will efficiently support the rectum, bladder, and genitals

5 If the cervix be *not pointed* and *retroversion* does not exist amputation of the cervix may be omitted in the above procedure

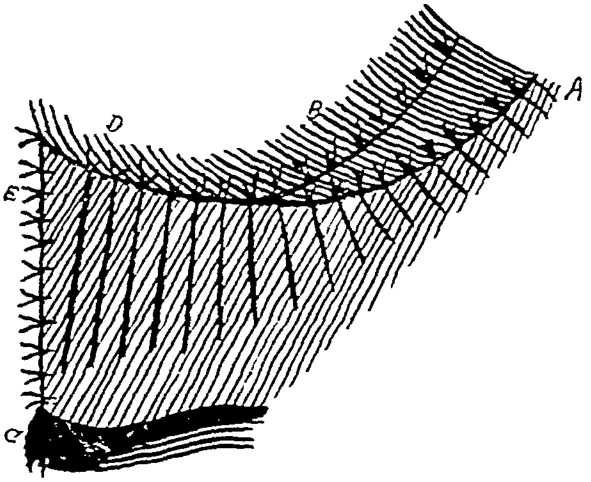

Fig 30—Profile view of A Martin's colpoperineorrhaphy posterior A B elytrorrhaphy D E C perineauxesis

6 If the uterus and bladder be in normal position and the vagina not prolapsed anterior colporrhaphy may be omitted

7 The permanent success of Tait's perineal flap *operation consists in extensive flaps* (*by means of* front and back cuts) and the drawing into the median line of large masses of lateral tissue for a pelvic floor These lateral masses are drawn in and secured for weeks by deep sutures of silkworm gut These deep sutures *six to eight in number, act like splints for* four to eight weeks, and though part of the wound suppurates, the sutures maintain it in coaptation while it granulates and heals

8. Our operations have proved definitely that the rectal sphincters may be practically restored to normal, even after long periods of rupture. One case of thirty-four years' standing, with two previous unsuccessful denuding perineorrhaphies and a complete laceration of three inches up the rectum was restored to perfect function.

9. The three surgical procedures described will obviate hysterectomy in many cases.

10. The flattening out of the operation, or the yielding of the union, or the stretching of the parts allowing prolapse, will depend especially on the flaps and the amount of tissue permanently drawn into the middle line.

12. We especially insist that better results are obtained by allowing the silkworm gut sutures to remain in position for from four to six weeks. Should any suppurate they may be removed at any time. Wounds do not heal very firmly under three weeks.

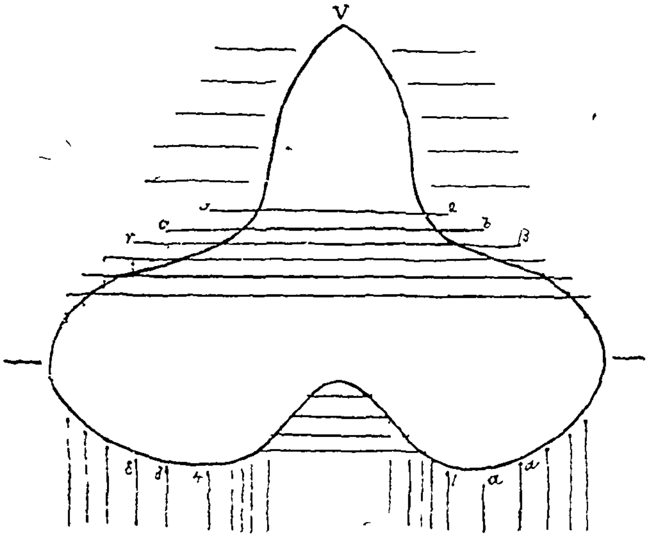

Fig. 31.—Hildebrandt's method of denudation and suturing. The dotted lines show the sutures under the tissues. The denuded area is that of a trefoil. Hepner's method of suture is that of a figure 8. Cleveland's method is simply a peculiar method of suturing.

13. We feel decided in stating from our own experience that the flap operation should not be disturbed by dressings. The patient should be kept quiet for three days, and then a vaginal douche may be given daily. After the first half day the wound is hermetically sealed by its own oozing. The limbs should be tied together at the knees. The bladder will generally require the use of the catheter for two to four days. Morphin injections of 1/16 of a grain may be given to quiet the pain and induce rest.

14. The dissection of the rectum from the vagina for one to three inches, was added from my own experience, as I never saw Mr. Tait do this. This additional procedure lengthens the operation to fifteen to thirty minutes, Mr. Tait performs his operation in five to ten minutes.

15. The result of the foregoing surgical procedure has been gratifyingly successful.

16. The flap operation fits any and every case, for it resplits the old cicatrix and restores and adds what is required.

17. In no single case, in over 150 which I have observed, was the flap operation not applicable.

18. The flap method makes little scar tissue, as the operative procedure is performed in connective tissue while cicatrices form in skin and mucosa. In the flap colpoperineorrhaphy the posterior vaginal wall is made to sustain the anterior.

19. In the flap operation the vaginal walls are made to give their full support to the uterus—the posterior wall sustains the anterior vaginal wall and bladder—and also to support and direct backward the rectal wall.

The flap perineorrhaphy has been chiefly revised and introduced to the profession by Mr. Lawson Tait of Birmingham, England. It is true the flap perineal operation was performed in various ways by others, as Duncan, Colles, Jenks, Marcy and Langenbeck. But Mr. Tait gave it a new impetus, and also performed it with new phases. He performed it with elbow scissors and introduced sutures which neither penetrated skin nor mucous membrane. As a pupil of Mr. Tait, for six months, I had ample opportunity to observe his methods of operation. The principle of operation consists in resplitting the old perineal cicatrix without loss of tissue, with fixed coaptation of the flaps. After observing Mr. Tait's methods I naturally practised the operation as performed by him and his assistants. About a year later I began to modify the operation by dissecting the rectum and vagina from each other for a variable but long distance (1 to 2½ inches) above the vulva or anus. This modification enabled me to apply it to almost all forms of prolapse, relaxed vaginal wall or perineal laceration, in short, in all conditions requiring perineorrhaphy and colporrhaphy posterior. The objections raised against the flap method we found, after over six years' trial, were not well founded. One objection is that Tait's flap perineorrhaphy is a "skin operation." If performed superficially it may be subject to the above criticism. However, such criticism can only be applied to imperfect execution. The operator must carefully guard against closing the vulva too far. One can easily make an excessive perineum by the flap method. This objection is, as a matter of fact worthless. Another objection is that the flap method in no way narrows the vagina. This objection will not hold, as the vagina can be narrowed so as to embrace tightly a single index finger. In fact, we can dissect the rectum and vagina from each other for three inches up to the peritoneum, or as high as desired and narrow the lower third of the vagina as much as the operator sees fit. The upper two thirds of the vagina does not require narrowing. Another

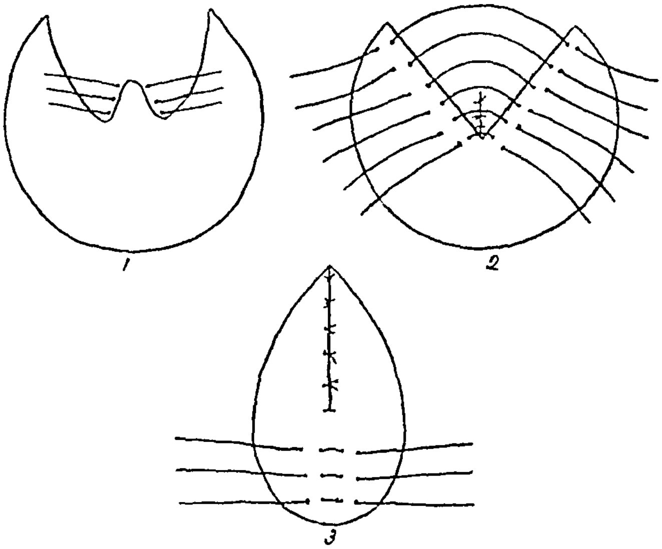

Fig. 32.—(After Pozzi.) Lautenbach's method in incomplete rupture of the perineum. 1, suture of the superior angle. 2, submucous suture of the vaginal wall. 3, buried sutures deep in the wound.

objection is that it does not approximate the fibers of the levator ani It is the operation par excellence to unite the deranged or torn levator ani fibers, because the dissection is carried beyond the levator ani fascia superior and inferior through the levator ani muscle In fact, it enables the operator to secure both the levator ani fascia superior and inferior, which embraces the levator ani muscle One must secure the levator ani fascia in order to secure the levator ani muscle, which is guarded and embraced by a definite fascial sheath The flap operation reunites the posterior vaginal fascial septum without denudation, as Emmet's operation unites it with denudation Both Emmet's and Tait's operations are based anatomically on the same principle—one denudes however, and the other does not, but employs a flap to cover the wound My practice is to dissect the rectum and vagina in the lateral sulci In the American Textbook of Gynecology the writer on "Flap splitting Perineorrhaphy' makes the following absurd statements "Its field of usefulness is very limited indeed Practically it is applicable to those cases in which only the superficial and most exterior fibers of the perineum are torn" The above views can certainly be based only on imperfect knowledge, execution, or observation of the operation We can affirm that it is one of the most certain and effective of all operations on the perineum The flap method of colpoperineorrhaphy is the one above all others that enables an operator to reunite the levator ani fascia superior and inferior with the enclosed levator ani muscle without blind searching, to abolish a rectocele, and to repair prolapse of the uterus The same writer cited above makes a further statement as ridiculous as the first, that, "In no way possible can this operation (flap-splitting) narrow the vagina, abolish a rectocele, or bring together the separated fibers of the pelvic

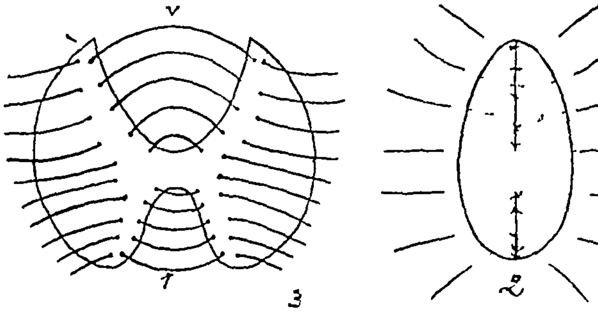

Fig. 33—Lauenstein's suture in complete laceration 1 introduction of sutures which coapt the vagina and rectal mucosa 2 introduction of the perineal sutures after the vaginal and rectal have been fastened

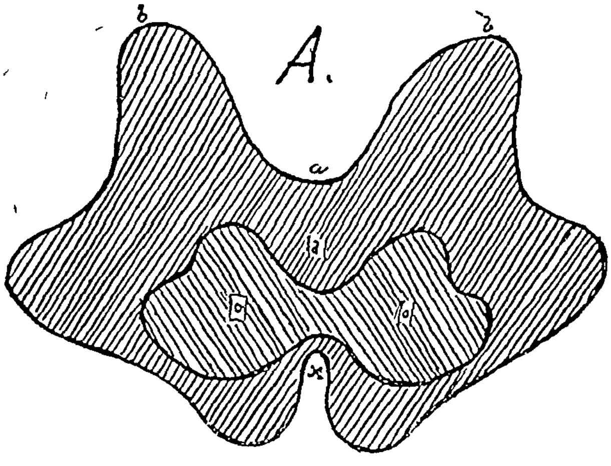

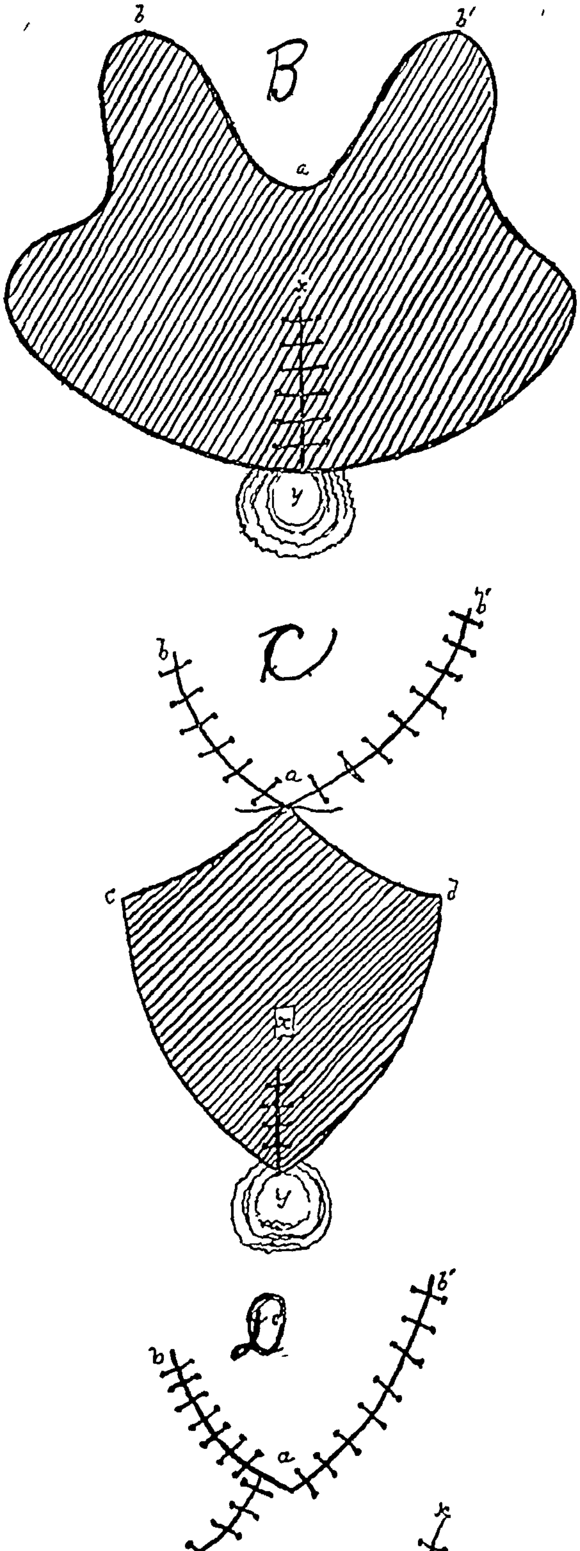

Fig 34 A B C D—(After Pozzi) Freund's method Freund insists that we should make the denudation exactly as the perineum appeared when originally torn For example the cicatrix O O originally appeared as large as B, B, X, in A and should be denuded to that size the line X, Y, in B represents the rectal suturing the line of sutures, B A B in C shows the vaginal part sewed up X, Y corresponds to the rectum suturing A C, Y, D in C the denuded perineal area which is still unsutured,

D the final disposition of the sutures in Freund's method It is an excellent one, but complicated and is wrought with much sacrifice of tissue if the operation fails

fascia " It is fortunate that this "American ' text-book does not represent the views of all Americans The flap splitting perineorrhaphy, in the hands of those who have thoroughly practised it has proved absolutely that it will narrow the vagina, abolish a rectocele, and bring together the separated fibers of the levator ani fascia superior and inferior with the fibers of the levator ani muscles Also it securely unites the ligamenta ischeo perinei The flap method is alike useful in partial and complete operations, and in high rectovaginal dissections does all that Emmet's does, with no denudations, and with a better chance of healing, by avoiding the infectious atrium Also, like Emmet's operation, Tait's flap-splitting is founded on anatomic structures and designed to restore physiologic functions Both operations have come to stay The conception of the flap-splitting operation rests on the pathologic conditions of the wound If one examines a vulva with lacerations, he will see linear cicatrices, narrow white lines which are transverse in dissection These white lines are the healed cicatrices of the old perineal lacerations The linear cicatrix is healed at right angles to the original wound or rent Wounds generally heal in the direction of the tear

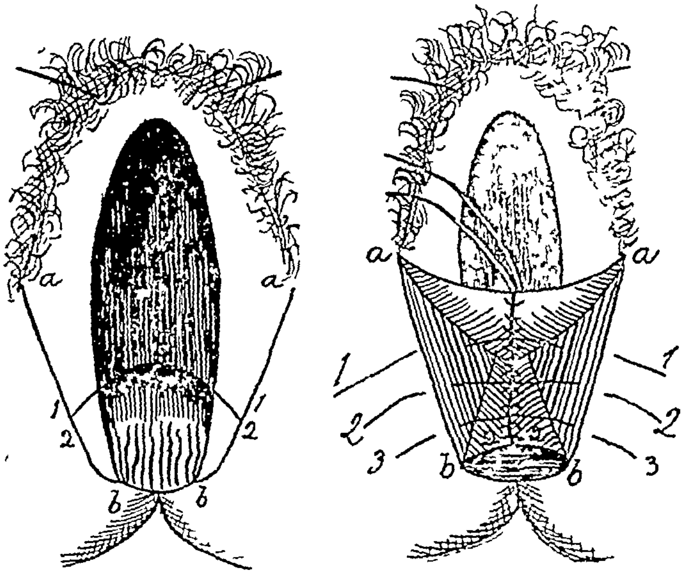

Fig 35 —(After Pozzi) A R Simpson's method It is really a flap operation In the left hand cut *a b* and *c* represent the lines of incision to make the flaps S vagina 1 1 vaginal flap 2 2 rectal flap The scissors are first entered at *b* and the point emerges at *a* and then a clip is made second the scissors are entered at 1 and pushed between the vaginal and rectal walls over to 1 and a clip makes the rectal and vaginal flap Dissect the vaginal flap from the rectal as high as the case requires To do this, seize the vaginal flap with several small forceps which the assistant can gently hold also seize the rectal flaps with several small forceps and allow them to hang as their weight is sufficient to put the flap on tension with the two fingers in the rectum and a pair of blunt pointed scissors the dissection of the flaps is conveniently made The sutures are introduced as shown in the cut Observe that in this operation four flaps are made and that the rectal and vaginal walls are sutured separately also note that the sutures 1 2 3 are entered by passing through the skin The suturing and flap making is absolutely different from that of Mr Tait's flap method in which only one flap is made and no sutures enter the skin or mucosa and all sutures are in denuded tissue

On this peculiar condition of the cicatrix being at right angles to the wound is based the flap splitting method of Mr Tait The transverse cicatrix is split and sutured at right angles to itself It simulates the Heinike Mikulicz pyloroplasty when the wound is sutured exactly in the opposite direction to its incision It is the same procedure as one may employ in varicocele to shorten the scrotum i e incise the scrotum along the spermatic cord for three inches and then suture the scrotal wound at right angles to the incision as is practised in Dr Senn's clinic In suturing the split cicatricial wound at right angles to itself we restore exactly the original normal structures of the perineum By this method the perineum and relations are restored to the normal condition which alone will withstand subsequent labors The patient should be prepared for three days before the operation by cathartics, so that the digestive tract may be thoroughly evacuated The cathartics should be so administered that all defecation should cease 8 to 10 hours before the operation There will then be no feces in the rectum during the [illegible] nor [illegible] hours subsequent The pat[illegible] the [illegible]

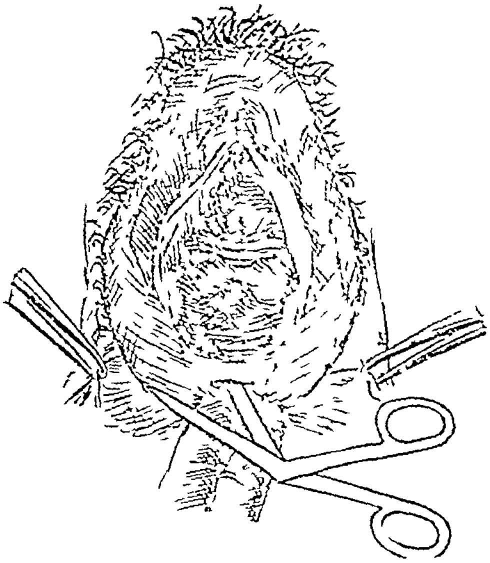

Fig 36 —A perineal laceration to the rectum Two fingers of the left hand are in the rectum the recto vaginal septum is put on lateral tension by the traction forceps on each side the blade of the scissors is inserted between the rectal and vaginal walls and the dotted line marks out the flap to be produced

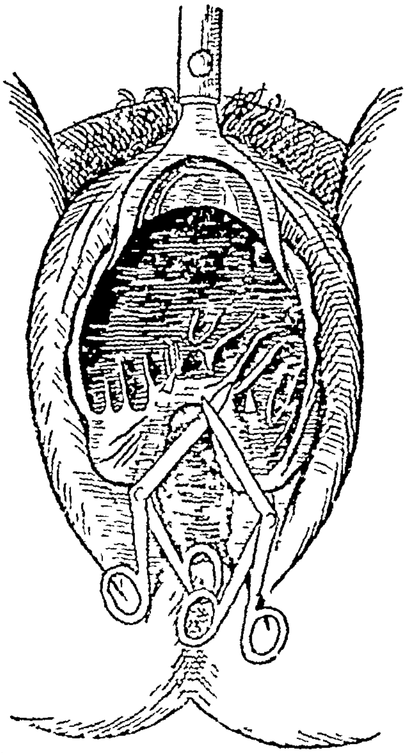

Fig 37 —(Modified from Pozzi) A very extensive rectovaginal laceration of old standing with large radiating cicatrix [illegible] healing line The scissor blade [illegible] introduced [illegible] the rectal and vaginal walls at the cicatricial margin [illegible] are produced Back cuts extend to the [illegible] are made to produce a large [illegible] into the vagina [illegible]

lies on the back The instruments useful in this operation are elbow scissors, a handled needle with an eye in its pointed end, and strong silkworm gut The silk worm gut should be thoroughly washed with soap and water The index and middle finger are introduced into the rectum, and the recto-vaginal septum is divided in the linear cicatrix The scissors point is then forced under the skin of the labia and carried upward as far as desired and clipped The opposite side is treated exactly the same Back cuts are now made on each side of the rectum as long as desired In slight operations the back cuts are not required The anterior vaginal flap is seized with forceps and drawn forward, while the posterior rectal flap is seized and drawn backward We dissect the rectum from the vagina as high as desired (1¼ to 3 inches) At the same time the lateral space on each side of the vagina is dissected as extensively as is required to make the perineal body (See Fig 19) The two fingers of the left hand are kept continually in the rectum as a guide The extent of the dissection is governed by the condition of the parts, the size of the wound, and the object in view, whether it be narrowing the vagina, extension of the perineum, or almost closing the passage for prolapse With considerable dissection, a few arteries may need clamping, however, the hot irrigation will nearly always be sufficient to check the hemorrhage If the bulb be cut it will bleed profusely, but sponge-pressure will soon check it If the scissors cut open a vulvo vaginal abscess the whole gland should be dissected out and disinfected, in order to avoid an abscess in the wound

SOCIETY PROCEEDINGS

Chicago Gynecological Society

Regular meeting held Sept 18, 1898

The President, Dr HENRY P NEWMAN, in the Chair

Dr JOSEPH PRICE of PHILADELPHIA (by invitation) read a paper entitled

ABDOMINAL VS VAGINAL SECTION IN PELVIC SURGERY

He said it was very difficult to consider some of the opinions of recent adoption by surgeons with a judicial temper and impartiality These different opinions had a surgical importance, in that problems arose, and their discussion would not and *should not down until they were satisfactorily settled If his* own views were distinct and had something of a dogmatic ring, it was because thev were forced upon him by actual experience and observation Many practising the vaginal operation had the impression that the operation had not been universally adopted because physicians did not understand it, that it was difficult, dangerous, or impossible in their hands, that it required for its successful performance a peculiar aptitude, a special training and adeptness This was a mistake A number of men who opposed the vaginal operation had done it successfully, their mortality had been quite as low as that of those who advocated and made the procedure their adopted one *They did the suprapubic operation, influenced by the* logic of their experience, by purely surgical and pathologic reasons, and it was the operation of their choice because it gave the most complete results, left less dangerous or annoying sequelæ, and less risk of the necessity for repeated operations By the suprapubic route surgical cleanliness and surgical completeness were possible, by the vaginal they were not The difference between the advocates of the abdominal method and those who critizised it was that the advocate spoke according to his knowledge and of the facts which actual clinical experience had *confirmed, the critic* according to his failures, disappointments and prejudices The one had uniform success sustaining him the other humiliating failures which inspired and gave color to his opinions The French and Belgians were never successful in doing the suprapubic operation The successful American, English and German operators had practised both methods for years, adopting the suprapubic procedure for tubal and ovarian disease, and the vaginal route for malignancy The results of these men were uniformly good, they adapted their operation to actual pathologic conditions, they operated for actual disease, and not for all sorts of fancied conditions, or for vague nervous disorders due frequently to emotional susceptibility

He said it was simply amazing how common it was with some operators to begin two distinct operations and complete neither Good operators sometimes made a free opening into the abdomen, inspected and backed out, and then attempted the vaginal route and abandoned it after the puncture of one or more accumulations and drainage The relief following mere puncture and drainage was only temporary The drainage of one or more pus pockets, where many existed in a large, tortuous, puriform tube or tubes, and where we had one or more ovarian abscesses, never cured The only cure was the removal of the diseased member He thought surgeons need only appeal to actual clinical facts in the experience of some prominent vaginal *operators to show how difficult and incomplete their work* was when they encountered deep seated and complicated pathologic conditions, and also in how very many cases the result was fatal In relation to results from any procedure, no reliance could be placed on the statistics of men who selected only favorable cases for operation and rejected the unfavorable These men in his opinion had no right to compare their results with those of men who did not reject the desperate cases Imperfect and incomplete work by the abdominal route was a feeble argument in favor of the vaginal The fault was not in the procedure, but in the operator, his lack of wide clinical experience in dealing with gynecologic troubles or lack of surgical courage to complete the work he began The removal of pathologic conditions was easier from above than from below, because the structures were more easily defined and lines of cleavage or enucleation were *from* important structures and not *toward* them or *into* them, there was no difficulty in *securing arteries, as they could be seen and felt pulsating beneath* the fingers The operation was precise, it could be made mathematically certain in its limits, the incision was directly under the eye and under the absolute control of the fingers, it was not a stab about in the dark among vital organs as in the vaginal route, it enabled the easy freeing of omentum and bowel when adherent, and the repair of all disorganized parts These were important considerations

Careful examination of statistics coming from reliable sources went to show that abdominal pain continued in very many cases operated upon by the vaginal route and followed too many imperfectly, incompletely and ignorantly operated upon by the suprapubic method These disagreeable symptoms complained of by patients after operation were nearly always the result of leaving omental and intestinal adhesions The profession was too prone to talk about the septic uterus A patient with a septic uterus was very ill and usually died speedily *There were few things that killed a woman quicker* than a septic uterus The essayist was daily doing sections, and while dealing with all sorts of complications and adhesions, dangerous twists and contortions, strong adhesions or fixation of crossed viscera, the sigmoid strongly adherent to the anterior face of the right tube and broad ligament, the cecum and appendix out of position and adherent, he could not but experience a sense of surprise that experienced surgeons (who have in the past done good abdominal work) could forget or ignore the lessons of their experience and deliberately extirpate the little healthy uterus and pass by pathologic lesions and complications constituting the real and only source of trouble Surgery would be more judicious and successful if more care and skill were exercised in determining definitely the trouble for which operations were performed and the procedure strictly adapted to actual conditions No one method should be pursued in all cases, the symptoms and conditions present must *largely guide the surgeon in the selection of a procedure* It was important to select with great care the cases favorable to the application of any particular method Sinuses were just as frequent and distressing in the vaginal vault as in the adbominal incision Menopause nervous phenomena were about the same in both procedures, when completed

In a series of 403 cases of vaginal hysterectomy, including *about all conditions for which it was done, total general prolapse* etc, Jacobs had 9 fistulæ after the operations, yet he said that "subsequent fistulæ were exceedingly rare" He had observed 5 intestinal, 3 visceral and 1 ureteral fistulæ Further, he remarks that "in most of the cases these fistulæ existed prior to the operation, there were fistulous passages which extended between the purulent foci and some part of the intestine These passages were so large, and with walls so well organized that the disappearance of the purulent pockets did not suffice to bring about the subsequent and spontaneous cure " In all such cases the speaker relieves adhesions, trims and repairs all lesions, with the most pleasing results, without any of the sequelæ of fistulous openings given by Jacobs as following the vaginal procedure

D **Fernand Henrotin** opened the discussion with a paper entitled

THE INDICATIONS FOR INTERFERENCE BY WAY OF THE VAGINA IN PELVIC DISEASES AN ANSWER TO DR JOSEPH PRICE

At the outset, he held that the vaginal route was a proper channel to attack pelvic disease in women in certain selected cases only As better inspection and palpation of the pelvic organs could be obtained by an abdominal incision, it was conceded that all patients to be operated vaginally must present special indications, and that in cases of doubt the abdominal incision was most proper In favor of vaginal section it may be said that where the same results can be obtained vaginally, this route should be accepted as it avoids the abdominal scar, lessens the shock and is much less frequently followed by hernia Although one of the first to advocate the treatment of pelvic affections by way of the vagina in selected cases, he was most willing to admit that this method was not so much in vogue with experienced operators as it was three years ago, and for very good reasons, one of which was that our knowledge of the prevalence of appendicitis in conjunction with pelvic trouble made it incumbent to operate by an abdominal incision when any degree of this affection was even suspected, and we had learned in later years that this condition was common The primary incision, whether it be through the abdomen above the pelvis, or through the vaginal vault, was to a degree always an exploration The infinite variety of intra abdominal complications made it so This primary incision was as frequently curative by way of the vagina, and even more frequently so, than the abdominal cut This was by reason of the ease and directness of drainage The early vaginal incision, to those who understood it and had the skill to perform it properly, was the ideal of conservative surgery This incision, like all vaginal operations, was only applicable to selected cases By early vaginal incision was meant an incision that cures the localized septic pelvic infection in its very beginning, the woman remaining thereafter not only symptomatically, but physiologically perfect It was particularly applicable to the treatment of acute ovarian abscess This disease he believes is more common by far than is generally supposed Its most general cause was abortion and trauma It was the most common extra uterine form of pelvic sepsis that occurred following early miscarriages, criminal abortion and unclean surgical manipulations After two or three days of fever the presence of exudate could usually be recognized at the sides or behind the uterus This meant ovarian abscesses in eight or nine cases out of ten

Vaginal hysterectomy was sometimes advisable, and in some cases was infinitely superior to any abdominal operation that could be performed on the same patient Experienced operators who were equally skilled in vaginal, as well as in abdominal work, were doing less vaginal work now than they were two years ago At least, this was his belief not because vaginal hysterectomy was not a very proper and sometimes the best operation to be performed in certain cases, but because it was a radical operation and because the field of all radical operations had been much restricted for the last few years Salpingectomy, ovarian resection, vaginal incision, had all done their share in the salvation of scores of uteri While abdominal operators were improving their methods and perfecting their results, the vaginal workers were developing the possibilities of the vaginal incision, and he claims today that one if not the greatest of modern conservative gynecologic triumphs, is the thoroughly understood and properly performed vaginal section in selected cases And there are many As regards vaginal hysterectomy, it still had in the opinion of the speaker, a perfectly defined position In women necessarily sterile and approaching the menopause, where bilateral periuterine septic disease existed and was situated low in the pelvis and with a roomy vagina particularly in those with extensive and disseminated suppuration who were low with septic fever and especially where the abdominal wall was very fat vaginal hysterectomy was still by far the preferable operation, and when skillfully performed in a large series would always give the best results To demonstrate his own opinion as regards selection Dr Henrotin presented a table showing the frequency of vaginal as compared with abdominal incision and the character of the intervention, from which it will be seen what an important factor the conservative operation has become, and frequently he believes vaginal section applicable These operations were performed from January, 1897, to July, 1898 Reference is made only to such as were done for clearly defined pelvic disease, and the list does not include abdominal operations on the kidney, liver, gall bladder, appendix, intestine (hernia) or any miscellaneous intra abdominal work in which the internal genitalia were not involved Of 180 such operations there were

SUPRAPUBIC CELIOTOMIES 132

Conservative operations on the adnexæ always leaving ovarian tissue and uterus	62
Double salpingo-oöphorectomy	4
Single salpingo-oöphorectomy for ruptured ectopic gestation	8
Myomectomy	3
Hysterectomy for fibroids	14
Hysterectomy for sepsis	8
Hysterectomy for prolapse	3
Miscellaneous operations for adhesions ovarian dermoid and intraligamentous cysts sarcomas and hard ovarian tumors, etc	30
	132

VAGINAL OPERATIONS 44

Early section for recent disease	8
Late section for old disease	18
Single salpingo-oöphorectomy	1
Section for large ovarian cyst and its removal after tapping	1
Section for septic ruptured ectopic gestation	1
Hysterectomy for sepsis	10
Hysterectomy for fibroids	2
Hysterectomy for cancer	1
Hysterectomy for prolapse	2
	44

Vagino-abdominal operations for cancer 4 Total 180

Dr **Franklin H Martin** said that the best all around gynecologist was the one who selected the operation suitable for the particular case in hand It was impossible to do good surgery by operating suprapubically or by the vagina in all cases It was his belief that all major surgery could be done best through the abdomen, as a rule, while all minor surgery could be done by the vagina All surgery of importance should be done through the abdomen 1, because the surgeon could see what he is doing, 2, he could do what he wanted, and 3, he could do it quicker The cases he would reserve for the vaginal route would be those of carcinoma of the cervix of the proliferating variety, or flat cell epithelioma filling up the vagina, but which seldom extended beyond the cervix, and infected the lymphatic glands In all other cases, where there was any question as to cancer involving the vagina, he would remove the uterus from above, and if later it was found that the glands were diseased, he would remove them also Cases of double pyosalpinx, large fibroids cystomata, and all cases of extra uterine pregnancy should be dealt with suprapubically

Dr **Henry T Byford** held that to operate on all cases either suprapubically or by the vagina was unreasonable He believed that just as efficient work could be accomplished by the vagina as through the abdomen There were certain pathologic conditions in the bottom of the pelvis in some cases that could not be operated as well from above as from below He emphasized the importance of carefully selecting the cases for either route

Dr **James H Etheridge** thought the discussion had the appearance of placing the advocates of the two operations in the attitude of rivals He did not believe this He held that we have two separate things to deal with, and that good work could be done by the vaginal or suprapubic method of operating There were cases in which the vaginal route was applicable, while there were others in which the abdominal method was suitable, and the wisdom and experience of such men as Drs Price and Henrotin could define the limits of those cases to be operated upon vaginally and those that were best adapted to the suprapubic route A strong objection to the vaginal route was that operators worked largely in the dark Hemostasis was unsatisfactory and, added to this, there was danger of wounding the bowel He had seen one case in which death was caused from wounding the bowel, but which was only discovered postmortem

Dr **Reuben Peterson** said that any one who had done considerable abdominal work must have seen cases that he dreaded to approach by the suprapubic route For many years nearly all work was directed entirely through the abdomen in dealing with the pathologic conditions under discussion Each method had its field of usefulness and it remained for gynecologists to select their cases and choose the method to employ

Further discussion of this subject was deferred until the next meeting

Dr **Emil Ries** read an inaugural thesis entitled ' Results of the Extended Operation for Carcinoma Uteri

PRACTICAL NOTES

Artificial Serum in Epilepsy.—De Fleury announces that injections of artificial serum enhance the effects of potassium bromid in epilepsy, so that much smaller doses are effective, with two or three injections of serum a day.—*Gazette Méd. de Liège*, September 15.

Creosote and Ichthyol for Tuberculosis.—H. Goldmann reports marked improvement in patients treated with ten to thirty drops of the following after each meal; Creosote carbonate, 15 grams; ichthyol, 15 grams; glycerin, 30 grams; peppermint water, 10 grams.—*Semaine Méd.*, September 7.

Gelatin for Gastric Hemorrhage.—V. Poliakov of Moscow reports a case of ulcer of the stomach with cardialgia, pyrosis and almost daily vomiting of blood for four months, which he treated with 10 per cent. gelatin three times a day, 2 c.c., for four weeks. It cured the hemorrhage and gastric pains, with no recurrence to date.—*Semaine Méd.*, July 27.

Automatic Kelene Tubes.—The *Gazette Méd. de Paris* mentions with approbation the automatic tubes for local anesthesia with chlorid of ethyl, which require but one hand, a novelty exhibited at the French Dental Congress, adding that experiments with chlorid of ethyl for general anesthesia now in progress promise very encouraging results.

Operative Dislocation of Goiter.—This is proposed by A. Wolfler for cases of inoperable goiter which threaten suffocation or interference with other vital functions. The goiter is detached from its bed, without disturbing the arteries, and transplanted to another place where it will not interfere to such an extent, usually higher up or farther around. He thermocauterized one case to reduce the size of the goiter, but he thinks it probable that the goiter would recede without this.—*Beiträge z. klin. Chir.* xxi, 2, in *Cbl. f. Chir.*

Mercury for Snake Bites.—The *Tribune Médica* of Rio de Janeiro, for June 10, describes the recovery of a young man after having beeen bitten by a cobra, causing in fifteen minutes intense headache, absolute blindness, copious hemorrhage in the spot, with alarming sweating of blood. He was given two grams of calomel and two of rhubarb at once, the spot disinfected, and the calomel kept up, six decigrams every six hours, until he had taken five doses. The writer has cured 128 persons with this treatment.

Subcutaneous Rupture of Large Arteries.—Traumatic occlusion of the large arteries from immediate obliteration, or a gradual obliteration from thrombosis, may heal without accident, but it is usually followed by gangrene—thirty out of forty cases. When called at once, and the indications of arrested circulation are noted, the first step is a careful disinfection of the skin, followed by wrapping the member in a thick layer of cotton without compressing it. This will prevent septic complications and if gangrene does occur, the chances are in favor of its remaining localized. The extent and gravity of the gangrene will also be reduced if the collateral circulation is promoted with prolonged hot baths. As the gangrenous accidents proceed less from the localized traumatic lesion of the artery than from the consecutive thrombosis and compression produced by the effusion of blood, it is wise to open into the periarterial sanguine focus, at least during the first few hours after the traumatism, evacuate it and ligate the ruptured vessel. At a later period, if the gangrene is menacing, high amputation may be required, but sometimes unexpected results are obtained with embalming, combined, if necessary, with extensive incisions, injections of very hot boiled water and wrapping in compresses dipped in alcohol. When the gangrene is dry and circumscribed, radical intervention should be postponed as long as possible, as it may prove unnecessary.—*Revue de Chir.*, April and June, 1898.

Lead Oxid Test for Urine.—Loubiou recommends the following simple test as very sensitive to small amounts of albumin, rapidly clarifying the most turbid urine. 1. Put 10 c.c. urine in a test tube with one drop of phenol phthalein and add normal sodium drop by drop until the fluid is slightly pink, reversing the tube on the thumb after each drop of sodium. 2. Add 1 to 1½ gram of lead oxid, shake well and filter. 3. The pinkish tint is removed by the addition of a few drops of Tanret's reagent. The fluid is then brought to the boiling point and the albumin precipitated as usual.—*Bull. de la Soc. de Pharm. de Bordeaux*, July.

Midwifery Practice.—Muir (*Annals of Gyn. and Ped.*, September), in "Notes from Midwifery Practice," says that 75 per cent. of the gynecologists, so called, live from errors or incidents occurring during the parturition state, and that seven eighths of the women coming under his observation (about 1600 confinement cases) for treatment, have been delivered by forceps. "Many a first class, honest, careful physician is turned to one side because he gives his patients time to be delivered naturally, and another employed simply because he has the reputation of not allowing his patients to suffer, but uses chloroform and instruments early. The latter is the man who gives the gynecologist his inning." His rule is to never remove the placenta until he can feel the insertion of the cord quite easily, and he never gives ergot unless he knows his patient's habits and that it is indicated; he gives it hypodermatically. "Another thing I have learned by experience," he says, "is never to underrate the idea of the patient that things are not right. Time after time, I have been told this, but thinking it only some hallucination on my patient's part, afterward I have learned to my surprise, if not regret, that she was correct." In breech or foot presentations he has found the pain continuous, and in some cases was obliged to resort to chloroform, slightly, on account of the severity of the pain. He has never noticed an excessive quantity of liquor amnii in breech or foot presentations, but has in a case of club foot. Whenever he has found an excessive quantity of amniotic fluid, the pains have been continuous from the first, also excessive and unnatural, and the patient has believed all was not right.

Fritsch's Incision in Cæsarian Section.—Steinthal (*Centralbl. f. Gyn.*, April 9, 1898) reports a case of Cæsarian section illustrating a complication which may arise in delivery through the transverse uterine incision of Fritsch. The patient was 34 years of age, and exhausted by long labor. The cause of obstruction was a myoma. Steinthal performed Cæsarian section by the method of Fritsch. There was little hemorrhage, as the uterine and ovarian arteries were controlled by manual compression. The child was partly extracted by the feet, but the head was held firmly in the uterine wound. It could be released only by making a vertical incision in addition to the transverse. An elastic ligature was then passed over the uterus down to the tumor. The placenta was extracted with but slight loss of blood. The tumor was found to be a subperitoneal growth with a broad pedicle, springing from the posterior surface of the uterus at the level of the os internum. Several knuckles of intestines were adherent to the tumor and had to be separated. Hysterectomy was performed, and the stump stitched to the lower angle of the wound. The author remarks that the object aimed at in the transverse incision was defeated by the necessity for adding the vertical section. Dr. C. Jewett (*Brooklyn Medical Journal*, September) believes Fritsch's incision can scarcely have any advantage over the longitudinal, provided the cut is confined to the upper or fundal portion of the uterus. Transverse section does not necessarily avoid the blood-vessels. Incision strictly in the median line would probably result in no more hemorrhage. Moreover, the vessels are easily controlled by manual compression or by the use of the cervical constrictor. All the advantages claimed for the transverse incision are realized in the longitudinal, by limiting the uterine wound to the thickened upper portion of the uterus.

SUBSCRIPTION PRICE INCLUDING POSTAGE
Per Annum in Advance $5.00
Foreign Postage 2.00
Single Copies 10 Cents

In requesting change of address give old as well as new location.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Bldgs.), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheet returned, or in regard to subscriptions should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, OCTOBER 8, 1898.

THE ANTITOXIN TREATMENT OF PNEUMONIA.

Dr. ANDREW H. SMITH of New York, in a recent paper[1] with the above title, read before the Association of American Physicians in May, states that it is very likely that in ordinary pneumonia there must be infection with succeeding generations of microbes. WELCH and others have shown that the virulence of the micrococcus lanceolatus is greatest when the coccus is youngest, that the most virulent microbes come from the edges of the consolidation. When the local process ceases to advance, it means that then young micro-organisms are no longer produced. This might be a reasonable explanation of the remarkable crisis in pneumonia, and yet the question arises what share do the antitoxic products play in the result?

As long ago as 1888 NETTER[2] showed that mice and rabbits can be made immune to the micrococcus lanceolatus by injection of fluid from the dried spleens of infected animals. FOA observed that attenuated cultures of the micrococcus may render an animal immune for several months. Taking the serum from an immune animal, he was able to produce immunity in a second animal by its injection. The KLEMPERER brothers verified these observations. They also found that dogs may be protected against pneumonia by the use of serum of immune animals. This serum does not kill the cocci in the body, but prevents the formation of toxins in the infected animal, either by hindering the toxicogenic powers of the cocci, or by rendering the toxin inert after it is produced.

The KLEMPERERS also showed that man is but slightly susceptible to the action of the micrococcus lanceolatus, especially to its action when injected subcutaneously. They conclude that in man it is not the exudation into the lung substance that renders pneumonia such a grave disease, but the general intoxication that results. Eventually antitoxin is produced and recovery may result. Serum taken from patients after the crisis, is found to have a curative action in dogs, and the crisis in human pneumonia is due to the production of antitoxin. The resulting immunity is in man only temporary, and while we await the formation of antitoxin we treat pneumonic patients by supportive measures, but in the meantime the old and weak die.

By using the antitoxic serum from animals apparent benefit in hastening the crisis has been observed, but a final conclusion as to the value of the treatment has not yet been reached. The following are some of the observations in regard to the serum treatment of pneumonia.

LARA used the serum of immune rabbits and dogs, as well as a glycerin extract from the viscera of immune animals, the latter was accompanied by less disturbance, producing no general symptoms. The crisis occurred in from three to five days, the convalescence was rapid and complete, and the reporter considered the results of ten cases thus treated as encouraging. BOZZOLO treated five cases with rabbit serum, the temperature fell rapidly in each case. Four recovered and one died after the crisis. DE RENZI states the results obtained by using antipneumococcic serum as decidedly encouraging. WEISBECKER obtained marked improvement in the subjective conditions very soon after the injection of serum obtained from patients recovering from pneumonia. One of the patients in whom these favorable results were observed was a 3-year-old child. The distressing subjective symptoms in many cases disappear as if by magic. WASHBURNE[3] in 1897 employed the serum of a pony which had been treated in the same manner as is now done in manufacturing diphtheria antitoxin, and this serum possessed marked protective powers. In some very unpromising cases this serum seemed to act favorably.

From this review of sero-therapy of pneumonia SMITH properly concludes that no decisive results have been obtained, but that there is sufficient to warrant further effort. There are very many difficulties in the way of this work. The extreme variability of the virulence of the micrococcus lanceolatus, and the corresponding uncertainty of the strength of the toxins produced are serious obstacles. Again, animals readily immunized may lose their immunity, and the serum from them becomes worthless. Hence conclusions can be established only with the greatest difficulty. Applying these laboratory observations to the clinical study of pneumonia, it will at once be seen that the difficulties are still further increased It is to be hoped that WASHBURNE's method of maintaining the virulence of the pneumococcus at a given point for a longer time may result in the production of a reliable antitoxin, and when a reliable antitoxin can be manufactured then the value of this treatment of pneumonia will soon be determined

THE MARRIAGE OF THE UNFIT

It comes, from time to time, within the editorial scope of the JOURNAL to notice propositions from medical sources to advance the public welfare by legislative or other limitations of the liberty or capacity of the individual to reproduce his species Sometimes it is in the form of a proposal to castrate criminals, sometimes in that of proposed or attempted legislation against the marriage of epileptics or other defectives, and it is not very long since, if we remember correctly, that a bill was before a certain State legislature to have appointed a sort of board of health to pass on the physical and mental—and we trust also the moral—condition of all candidates for marriage A similar proposition was, it is believed, also offered in France, but went no further than the medical, and probably some of the secular, journals, the conditions there at the present time exciting more anxiety on account of quantity rather than of quality of the population As a medical question, however, it is still a living one, and probably will be until our medico sociologic ideals and theories have more fully won their way into the practical usages of life, and can be effectively embodied into actually enforceable laws

In the London *Lancet* of September 10, Dr HARRY CAMPBELL publishes an article on "The Marriage of the Unfit,' that is as radical in its views, if not in its actual proposals, as any that have appeared upon this general subject He would prohibit or discourage marriage by, not only those who have suffered or are suffering from insanity, epilepsy, tuberculosis, heart disease, etc, but also by all who have or have had rheumatic fever, strangulated hernia, ovarian cyst, congenital defects of hearing, or any one of the chronic or acute functional nervous disorders, in fact, he would prohibit marriage altogether to that large class who are included under the general head of neurotics While he does not propose legislation to this effect he holds that as physicians, we should use all our influence to prevent marriage by those suffering from the above-named disorders and do our utmost to create such a higher ethical standard upon physiologic questions of this kind as would secure that such a self-denying ordinance could be possible on the part of the public that is specially concerned He goes even further in his enthusiasm for the welfare of the race, while, from a sociologic point of view, he condemns polygamy, as a biologist, he regrets its discontinuance in civilized communities, and wishes that it could be utilized for multiplication of the progeny of our athletes and intellectual giants

The basal idea of Dr CAMPBELL's argument appears to be that, while natural selection is interfered with in the human species, the subsequent modification of the process called by WEISSMANN "panmixia" is still more interfered with, and the result is a racial deterioration Mankind does not advance physically by natural selection and does not adapt itself to its environment by panmixia for the simple reason that every one follows blindly his impulse and recklessly procreates, whether fitted for the function by a good heredity or not Heredity is universal, the structure of any organ determines its reactions to any given environment, and structure is determined by heredity Hence, according to his theories, the importance of an unexceptionable heredity and the need of restricting marriage where such does not exist

The weak point in Dr CAMPBELL's argument—and it is the same in other similar statements of theories that would restrict marriage to any general or large extent—appears to us to be chiefly in that it does not take due account of the fact that Nature, in the operation of natural selection and panmixia, does not produce its results except through numerous experiments and failures, so to speak, and that these are as essential in its processes as are its successes If we could eliminate all morbid or variable heredity in humanity or any section of it, it would require an absolutely unchanging environment to preserve its immunity, and progress in any direction would be perilous or impossible The higher the state of culture or civilization the more complex are the conditions or problems of evolution and the more difficult will it be to modify them by any mere legislative restrictions or even by recommendations of individual self restraint We may advise as physicians but it would be presumptuous for us to expect our professional opinions to often outweigh the strongest personal impulses, to say nothing of social and other factors involved

The State can reasonably interfere in prohibiting the marriage of the insane and also—perhaps, with less prospect of success—that of the tuberculous and epileptics As regards the other disorders mentioned by Dr CAMPBELL, it is hardly likely that even medical advice will be often asked, much less accepted When we take account of all the vicissitudes of nervous and mental development and the absolute lack of any positive normal standards, any wholesale discouragement or even disparagement of the marriage of neurotics—including under this head all those who have suffered from functional disorders—might in certain points of view seem actually perilous to the welfare of the race The existence of a functional nervous disorder may be only an incident of a higher evolution, not by any means an indication of deterioration demanding the extinction of the family of the possessor

RENAL STONE

One of the most curious facts of our latter day science is the correction of statements of symptoms which have been calmly accepted by medical writers for many years It is perhaps too much to expect of a writer that he should have personally verified all statements of which he is the accredited author Indeed, the experience that would warrant one to write a book on such terms would take several centuries of constant clinical work and study to acquire Thus it is then that assertions made by many writers become finally elevated to the dignity of facts, and it is not until some self-assertive scientist, who only believes what he himself is able to prove, happens upon the scene, that the flimsy foundations upon which some of our most important diseases are constructed become suddenly undermined Again, with the accession of new instruments of precision many new symptoms are necessarily added and others are proved to be false

The introduction of the centrifuge into the examination of urine has elicited many facts not before in evidence, on account of the chemic changes occurring in this excretion during a lengthy sedimentation This instrument has brought out some new facts in regard to renal stone as related by MUSSER It has always been held by all authorities, and text-books have so stated for many years, that while hematuria is a common symptom in renal calculus, the appearance of blood is intermittent and can usually be appreciated by the naked eye , MUSSER has shown in some twenty cases that blood is persistently present, that is to say, from week to week, though individual specimens may occasionally show an absence of red cells after the usual examination While acknowledging an intermittent macroscopic hematuria, he claims and bears out his claims with laboratory facts, that blood in the urine is, in stone, a practically constant symptom, though oftimes the microscope becomes a necessity for its clinical demonstration "A few corpuscles only may be found, but one alone means hematuria" With the older writers, hemorrhage not appreciable to the naked eye necessarily escaped attention, and this latter symptom occurring only at irregular intervals, bears out their statements of an intermittent hematuria Thus it is with the introduction of new instruments symptoms once looked upon by us as well grounded, must, as a matter of course, undergo more or less change

On the other hand, a symptom assumed by almost all the writers on this subject as of constant occurrence pyuria, is claimed by MUSSER to be frequently absent He says "Of the twenty-eight cases I examined, in fifteen there was no pus in six a few cells of a very small quantity was found (four, womb, cause obvious) in one it was noted as considerable (old gonorrhea and syphilis, four examinations) in one only a small quantity (male cause assignable), in one it was small in amount, twice only in some fifty examinations in one it was abundant and due to genito-urinary infection as well as pyelitis" That the diagnosis of calculus was correct in these cases, subsequent operation or colic with the passage of the stone proved beyond a doubt From these facts, thoroughly worked up as they have been, the author is justified in his statement that pyuria is not a symptom of stone, except that there exist in addition to the calculus, some other lesion or lesions of the genito-urinary tract, which latter could of themselves account for the pus

In the microscopic examination of his cases, MUSSER has in many instances found hyaline casts, long and thin, undoubted evidence of renal irritation Other forms of casts do not occur unless a co existing nephritis be present This point, together with the presence of a small amount of albumin in a urine of high specific gravity, he looks upon as of great importance both from a diagnostic and prognostic outlook Here we have a symptomatology formulated, at once greatly opposed to the previous ideas held upon the subject, and it is to be hoped that further and more extensive observations will be made, that the diagnosis of this important affection shall not be compelled to remain in doubt

ACROSS THE PACIFIC IN TRANSPORTS

Manila is a long way from the United States The troops of the first expeditionary force sent out to support Admiral DEWEY passed thirty-seven days on shipboard before coming in sight of the scene of their future operations They embarked May 24 at San Francisco, Cal , and reached Manilla bay on June 30 It takes a much longer time for detailed medical reports of the voyage to make the return passage across the ocean and the continent to the Surgeon General's Office at Washington, D C , because they have to pass through so many headquarter offices while en route Sanitary reports are called for by the Surgeon General on the last day of every month, and some of those written June 30 by medical officers who accompanied the expedition have but now reached their destination These give a brief but interesting view of the conditions affecting the troops on their long voyage and in them there is nothing of the sensationalism which attended the movements of nearly every troop ship on the Atlantic side of the country

The steamship *Australia*, which carried General ANDERSON, his staff and 777 officers and men of the Second Oregon Infantry, was a passenger steamer hastily fitted out as a troop ship The berths were originally planned to be in sections of five abreast and three tiers high, but as it was considered that this would crowd the men too much, the middle row of berths was removed from each of the sections so as to have an aisle or free passage-way between every set of two rows Major M H ELLIS, surgeon of the regiment, regarded these berths as commodious and comfortable considering the conditions The men occupying those parts of the vessel that were most crowded or least desirable were permitted to bivouac on the main and hurricane decks in favorable weather, and the weather was favorable during no less than thirty-five of the thirty seven days The *City of Sidney*, which touched at Guam Island, carried 398 officers and men of the Fourteenth U S Infantry, 343 of the Second Oregon Infantry, 21 marines and 60 Spanish prisoners, without inconvenience or overcrowding, according to a report by Captain H E McVAY, assistant surgeon, U S Army The water supply was pure on both vessels It is reported of the *Australia* that after leaving Honolulu the issue of water was kept under careful surveillance to prevent waste The average daily consumption by the troops and crew was 1,200 gallons, of which one-half each day was condensed and filtered through charcoal All refuse material was thrown directly into the sea, and the latrines were constantly flushed with running water The food supply was ample, although bacon was but little used Dr ELLIS considered that the absence of fruit from the food issued to the men, with the sedentary habits necessarily imposed upon them by confinement on board ship, was productive of a tendency to constipation Dr McVAY characterized the clothing as wholly unsuited to the climate The blouse, cap, campaign hat and underclothing were all too heavy, and the overcoat a mere incumbrance Canvas uniforms were issued during the voyage to the troops on the *Australia*, but these were found also to be too heavy It is to be noted, however, that after the arrival at Cavite light underclothing and gingham blouses were immediately issued, and it is reported that the campaign hat proved more serviceable than was expected, for during the heavy rains it was preferable to the cork helmet

Notwithstanding the difficulties in the way of effecting cleanliness of the person and of the clothes, the condition of the troops at the end of the voyage was commendable On the *Australia* the underclothes of the men were regularly exposed to sterilization by steam in the absence of laundry facilities The health of the men was good Measles prevailed on the *City of Sidney*, but no case was serious One death occurred on this vessel from appendicitis, for which operation was performed

These records of pleasant and healthful voyages on the Pacific lead us to consider whether the War Department, under whose orders they were made, should be held responsible for the sickness and suffering incurred on other troop transports sailing under similar orders and under the same military regulations

---

Suicides in Italy —During 1897 suicides numbered 1997, which corresponds to a mortality of 8 41 for every 100,000 inhabitants The majority of the cases were in provinces where the ratio of illiteracy was the lowest

CORRESPONDENCE

Camp Thomas and the Second Division Hospital—The First Army Corps

INDIANAPOLIS IND , Sept 24, 1898

To the Editor —In view of the great concern now being manifested with regard to our military hospital service, I feel that a short statement as to the real condition will not be amiss

Leaving Indianapolis as Surgeon of the One Hundred and Fifty eighth, with Dr H I Jones, First and Dr Paul Barcus, Second Assistant Surgeon, we reached Chickamauga, May 18, 1898 The country was slightly rolling, with an almost regular alternation of wooded and open land Everywhere were evidences of a lime formation, with many vertical out croppings of the strata In the necessary trenchings the soil was found to be a clay so impervious to water that collections in sinks, etc , would evaporate rather than seep away into the subsoil Owing to the rocky formation at the depth of about seven feet, sinks were at that time a practical impossibility On May 25 I was ordered away from the regiment and detailed as Division Surgeon, having charge of the Second Division Hospital, First Army Corps At this time there was more or less confusion in all departments, nor could anything else be expected There were thousands of troops pouring in daily, few of whom were experienced in the matters of government account, all eager and questioning as to their individual duties It is a matter of wonder that the service was conducted so well We were on the line of the Southern R R and traffic was tremendously congested, the time not having allowed of building of switches and facilities for loading and unloading cars For a short time it was a question of doing the best that could be done until these faults might be remedied and the various departments maintained with some system I saw no instance nor heard of one where these temporary delays caused either suffering or hardship

Early in June I was ordered to begin the formation and organization of the Second Division, First Army Corps Hospital Police details were made, and requisitions forwarded asking for the necessary supplies These could not always be immediately had for the asking, but never was I told to "rustle" for myself The officers at the supply stations were universally courteous, and particularly Major Comegys, Chief Medical Purveyor With certain articles not at hand, the question would naturally follow, when can I get them? Whereupon the reply would likely be "I can not say definitely , they have been shipped and as soon as they reach us you will be welcome to them " Often the invoice would be shown showing date of shipment from the contractors This uncertainty was, I suspect, in a large measure due to inadequate railroad equipment and an enormous shipment of all sorts of supplies As time went on these difficulties were obviated and delays became fewer and fewer The hospital was soon opened, the regular United States army hospital tent being used, these were floored The natural drainage of the site was good Our water supply came from distant springs, being hauled in new, clean, sweet oak barrels Later, filters were added to our equipment, and the question of water supply was settled for all the time we remained in Chickamauga Food was always sufficient and of good quality On rare occasions the milk supply would be found sour, leaving us until the following day short of this one article of diet, which was invariably made up by soups, broths, bouillons, etc The medical supplies and surgical outfits, so far as essentials were concerned, was ample Men with pet remedies and hobbies would probably have been disappointed Flies were present throughout this great camp in unnumbered millions, but for this the medical department refuses to assume responsibility We met this annoyance by use of musquito nettings The success of the measure was not complete, for much of the time the weather was close and sultry to an extreme In going through the wards these nettings would be found wadded up and lying on the foot of the patient's cot or on the floor, with the explanation that it was thought to be cooler without them, that "they stop the breeze," etc So, in many and the majority of cases, these sick boys chose what little breeze might be finding its way into their quarters, and fanned the flies away in preference to being covered by a mosquito bar When we left Chickamauga it was with 100 large, new, unused and uncalled for mosquito bars

As to the criticism of their being too many autopsies, personally I remember of but two, and there was a universal feeling that where it could be dispensed with it should be so in consideration of "the folks at home" This criticism is uncalled for and absolutely can not be substantiated Up to the time of treating about 900 patients there had been but fourteen deaths, one of these a broken neck, another a typhoid hemorrhage that occurred on the night of the afternoon of admission, still another of cerebral effusion, when death occurred on the same day These are just three of the fourteen that I happen to recall, and when you consider the seriousness of the class of cases treated, the record can stand almost without a challenge Inspectors from the Medical Department at Washington were frequent in their visits, and their reports gratifying to the entire hospital staff

In the One Hundred and Fifty eighth Indiana, during the almost five months, there have been but five deaths, and this an organization of over 1300 men living under new and perhaps adverse circumstances, and certainly with a most radical and complete change in their habits of living This, I believe will speak for itself Instead of indulging in cheap criticism I would rather feel the gratification of great work accomplished in wonderfully short time and practically without any preparation

Fred R Charlton, Major and Surgeon,
One Hundred and Fifty eighth Vol Infantry
224 North Meridian St

Judge Kohlsaat and the Probate Court

Chicago, Oct 3, 1898

To the Editor —As long as the medical profession prides itself on keeping out of politics, it will be discriminated against by the politicians and the courts The action of Judge Kohlsaat toward our profession and our bills has become so outrageous that it is of vital importance that we take steps to protect ourselves from his lawless treatment The judge has made some rulings about which every one of us should know and we should thoroughly understand their effects on our welfare There have been many criticisms of his arbitrary rulings, but two in particular which are thoroughly authenticated I will give It must be understood that only claims against estates come up in the probate court The two decisions which, according to his own statement, are permanent in his court, are as follows First "I will not allow more than one doctor bill against an estate" This statement was made to the writer in the presence of Dr Bayard Holmes Dr John A Robison is authority for the second, which is "I will not allow any doctor's charge of more than $2 a visit' But few words are needed to emphasize the utter injustice of these decisions Not one operation in a thousand can be safely performed by one doctor working with other than professional assistance It is essential to have two or more physicians at every operation of importance but only one of them can secure remuneration for his services before Judge Kohlsaat I have a patient who lives nine miles from my home and at every visit I spend an hour dressing two large suppurating wounds Judge Kohlsaat thinks $2 ample remuneration for this work A short time ago I was called out at 1 o'clock A M , and found a man with impaction of feces, in pain like a woman in labor, with perineum bulging two or three inches under the involuntary straining, the patient in imminent danger of rupturing an intestine or a blood vessel I spent three hours with hot soap water, an irrigator and a spoon in removing the contents of the rectum and opening up the bowels A more disagreeable task it would be hard to find, and yet had my bill come before Judge Kohlsaat he would have considered $2 ample pay

If Judge Kohlsaat's decisions were in accordance with the law, an anesthetist could not recover pay for his services and neither could the consultant There would be nothing left but for them to demand their fees before responding to a call I have no doubt that Judge Kohlsaat has many times, as a lawyer, charged, in his office during office hours, $10 for answering a question involving a few hundred dollars Some lawyers have told me that it is the probate judge's business to protect estates I understand that it is the province of a judge to see that justice is done between litigants, and not to take one side or the other under his wing and waive off all claims whether they are just or not If it is foreordained that one judge is to decide all cases which come before him in favor of the defendant, and that another will decide all cases coming before him in favor of the plaintiff, we might as well abolish courts altogether People who inherit money are very apt to grasp at every dollar and to be unwilling to pay even the most sacred obligations of the man who accumulated the money and left it to them There are altogether too many men who are willing to live at the expense of others, and particularly are they willing to be parasites on the medical profession But why should such avaricious parasites be the special wards of a court that has been instituted to the end that justice and not injustice prevail? Judge Kohlsaat has allowed three liquor bills against one estate, but he will not allow more than one doctor bill Are liquor bills three times more important than doctor bills? Judge Kohlsaat seems to think so It is likely, however, that liquor dealers are three times more active in politics than doctors are If we, as a profession, will be a little more active in politics, we will be treated a little more respectfully by politicians and by courts

Judge Kohlsaat arrogates to himself the right to establish for our profession a fee bill and to control our method of doing business, and since he does so he is not a fit man to hold the position he occupies, and I propose that we unite and oppose his re election with all the influence at our command I now have the names of twenty five republicans who have promised to vote against him at the coming election, and if each doctor who is in sympathy with this protest will get ten republicans to vote for his opponent, we can defeat him and then we may hope to have our position in the community respected and our services appreciated even in the probate court

Tubal Pregnancy at About Two Weeks

Washington, D C , Sept 27, 1898

To the Editor —The report of the case of tubal pregnancy with rupture at about the fifth week, by Dr J L Cowles of Los Angeles, Cal , in the Journal of September 17 recalls a case of early pregnancy in which I made a postmortem examination April 1 1898 on the wife of a physician who had suddenly died She was 28 years old and had been married ten months Her menses had recurred regularly the last period being about the middle of March and unusually profuse March 30 there was a show of blood by the vagina, two weeks after cessation of the last flow April 2 sudden nausea, omiting and tendency to collapse but no pain Death next day about twenty four hours after these symptoms appeared The postmortem examination showed a general bloodless condition,

and a large quantity of blood and clots in the pelvic cavity The uterus was three inches long and contained a decidua The right tube just beyond the tubo uterine junction was somewhat enlarged and showed on its upper side an opening of rupture The ovum was found and was about two weeks old, the membrane and villi distinct but the embryo not distinguishable The right ovary contained a corpus luteum There were old peritoneal adhesions around the left tube and ovary The specimen is in the museum, No 10,545 The husband stated that intercourse occurred on the second or third day after cessation of menses D S LAMB, A M, M D,
Army Medical Museum

PUBLIC HEALTH

Variola and Tuberculosis—Landouzy called attention ten years ago to the fact that variola predisposes to tuberculosis, and Lop now reports sixty four observations that confirm the statement, with fifty four from Professor Revilliod and twenty two from Chauvin The tuberculosis is more severe as the intervening period is shorter —*Bulletin de l'Acad de Méd*, September 6

Treatment of Nervous Dyspepsia—Murdoch (*N Y Med Jour*, September 24) believes strychnin and electricity the most efficient agent in restoring the lost balance of the secretory nerves, while bathing is not to be neglected and diet to be properly regulated Much patience is required on the part of both patient and physician Often patients take too little food, only increasing the difficulty, the stomach also suffering from lack of nutrition

Venereal Diseases in the Russian Navy—The report of the Sebastopol division shows that the strict hygienic measures, careful medical supervision and instruction of the men in regard to venereal diseases by popular lectures, reduced the number of cases from 887 in 1893 to 556 in 1894 The number of soft chancres fell from 297 to 70, and the proportion of venereal diseases in the hospital from 45 to 25 per cent, in spite of the onstant increase in the number of the marines —*St Petersb led Woch*, September 4

Nitrous Poisoning By Canned Food—A special committee of the ondon Chamber of Commerce has for some time past been engaged in investigating cases of alleged poisoning through eating tinned foods, with the result that it has generally been found that such allegations were unfounded The latest case investigated was that of a young woman whose death was said to be due to ptomain poisoning consequent on eating tinned salmon, the contents of her stomach having been analyzed by Dr Stevenson of Guy's Hospital, the well known Government expert Dr Stevenson's opinion was that the death was due to poisoning by niter, and could not be attributed to ptomain poisoning through eating tinned salmon In the course of his evidence Dr Stevenson said that if, as had been stated, as many as 209,000,000 tins of food were consumed in one year, the cases of poisoning were infinitesimal His opinion was that so far from ptomain poisoning being specially identified with tinned provisions, it also arises in connection with fresh meats of all kinds

Yellow Fever—Since the reports from the South, in our last issue (p 803), the press dispatches have given the following data September 27, 5 new cases were reported at Jackson, Miss, 4 at Taylor's Station, 2 at Orwood, 4 deaths at Oxford, 1 new case at New Orleans, with 1 death, 8 cases at Wilson, and 5 deaths at Franklin, the total cases at this town being 129 to date The reports for September 28 give 5 new cases at New Orleans, with 1 death, 11 new cases at Wilson, 8 at Franklin, 1 at Oxford, Miss, and 2 suspicious at Clinton, near Wilson September 29, New Orleans reported 1 new case, Houma 1, 4 at Wesson, 8 at Franklin, 2 at Taylor's Station, Miss, and 3 at Oxford Six new cases at Wilson, 13 at Franklin, and 1 at Jackson, Miss, and 6 with 2 deaths at New Orleans, make up the record for September 30, while October 2 reports gave 2 new cases at Taylor's Station, 1 at Oxford, 10 at Jackson, 3 and 2 deaths at Harriston, and 1 suspicious case at Port Gibson As we go to press, dispatches of October 3 announce 9 counties and 13 towns infected in Tennessee The Port Gibson case is declared genuine, 1 new case at Jackson, 2 at Water Valley, and 16 with 1 death at Oxford

School Quarantine in Diphtheritic Cases—Dr Hand of Philadelphia has offered a suggestion which, if fully and officially confirmed, will tend to lighten the onerous treatment of scholars, teachers and nurses in our public schools and elsewhere who have been the subjects of school detention on account of diphtheria *His suggestion is not unreasonable, and it appeals to* our conservative feelings, in that it appears to open the way to a reduction of the term of ostracism now regarded as necessary by very many of our health officials He has recommended a solution of nitrate of silver, 60 grains to the ounce of water, to rid the throat of bacilli after the disappearance of diphtheritic membrane Often after the throat is entirely clear and the patient apparently well, examination shows that bacilli are still present In such cases quarantine must still be observed Hand reports good results from this method, the bacilli usually disappearing within a very few days The solution should not be used until the membrane has disappeared Now it may be that the silver solution may be less desirable than some others It may be that a solution of formalin will "fill the bill", we incline to think it may, but we trust that Dr Hand's suggestion may lead up to a mitigation of the scholastic penalties that are visited upon diphtheritic pupils in almost all of our cities —*Cleveland Med Jour*

Free Medical Assistance in France—We note in the official reports that France, with a population of thirty eight millions and a half, has nearly a million and a half of indigent persons, of whom 375,000 are inscribed as sick The country physicians are paid to attend them and the total thus disbursed in 1895, the first year the scheme was practically in operation, amounted to 1,771,472 francs Each one of the 12,000 practitioners received, on an average, about 150 francs The average to each physician is thirty patients, with three or four visits to each, at about thirty cents (a franc and a half) for each visit The *Gazette Méd de Paris* observes that there are a number of departments in which this service is not yet fully organized, and there are many districts too poor to meet the expense, others in which the remuneration is much below the average, "but on the whole, the philanthropists who have conceived and carried this law into execution have accomplished an excellent work, from the social point of view, if not from the medical " The total expense includes hospital and midwife service, transportation, instruments and medicines, and amounted to 4,898,680 francs This expense was shared by the community, the department and the State, respectively 3,600,002, 1,104,710 and 305,196 francs The first article of the law states in effect "Every sick French person without resources receives, free of charge, from the community, the department or the State, medical care at home or in a hospital Lying in women are included in these provisions Sick foreigners without resources are also included if the government has entered into a treaty of reciprocal assistance with the nation to which they belong "

Good Sanitary Results at Santiago de Cuba—General Leonard Wood, M D, as military governor of Santiago de Cuba is almost working miracles with the dirty old town Along with a committee of surgeons he has made a house to house visitation, and enforced a general cleaning up of houses and other buildings as well as of streets and public places At the time of American occupation the deaths in Santiago numbered 103 a day, but after three weeks of General Wood's rule they had been reduced to 37 a day Our editorial prediction of the salutary results that would follow General Wood's appointment as military governor of Santiago have been verified In this relation the *Medical Record* says that under General Wood's system Santiago is divided into five sections, each one under the general supervision of a medical man, who has under him inspectors of sewers, streets, houses and dispensaries, and a number of street cleaners Five hundred cubic yards of refuse are burned daily, disinfectants are distributed wherever they are needed, and a heavy fine is imposed for uncleanliness or for any failure to report unhealthful conditions and deaths The results are shown in a decrease in the death rate within a month from an average of seventy to one of twenty a day Among the troops the principal diseases are typhoid, malarial and yellow fevers and dysentery, The cases of yellow fever, several of which have been among the so called immunes, are few in number and the disease is of a very mild type The mortality from malaria or dysentery is much greater than that from yellow fever Now that the Spanish troops have all left for Spain, it is hoped that yellow fever can be made still less dangerous through the continuance of Dr Leonard Wood's good work

Scarlet Fever of Swine and Kine—In the *Centralblatt für Bacteriologie*, Dr Behle of Frankfort has a paper on the above subject It has for several years been, in England and Germany at least, fairly well proven that kine are susceptible to scarlet fever, though in a modified form, dependent on histologic and other difference, transmitting it again to man, in whom it resumes its normal characteristics The disease of swine, known as *rothlauf* in Germany, and as *rouget* in France, is in England popularly called "pig's scarlatina," on account of the red erythematous eruption on the skin, but the absence of renal phenomena, and the fact that lesions of the intestines are an essential feature, would suggest a nearer relation to enteric fever But Behle reports a remarkable outbreak of what appears to have been the true human scarlet fever in swine He states that in a district where *rothlauf* had never been known, a severe epidemic of scarlet fever among the children was followed or accompanied by a very fatal disease among the pigs at the same farmhouses and cottages The symptoms included erythema, angina, albuminuria, and those of uremic poisoning, which (or the angina) were the usual causes of death, while in such as recovered desquamation of the skin was well marked The lesions in the kidneys, observed after death, were very characteristic A previously healthy pig having been inoculated with the blood of a child suffering from a severe attack, died after a week's illness with symptoms and postmortem appearances which were identical with those seen in the human subject and in the animals which had contracted the disease presumably from the children or from one another If the facts be correctly reported, the conclusion that swine are susceptible to true scarlet fever is irresistible

Vaccination Laws of Pennsylvania—Dr Benjamin Lee, in *Public Health*, September, speaks favorably of the situation, in his State, as to the prevention of smallpox The existing enactments are not up to the ideals of an experienced sanitist, but they accomplish great good He says to his colleagues in health work "We shall make a great mistake if we attempt to interfere with the law I believe that with persistence in enforcing it our people will become educated to it and the difficulties will vanish" The phase "successful vaccination" is the stumbling block, and I believe that every local board has the right to interpret that phrase and give the decision according to its judgment The decision of the State Board of Health, by resolution, is to the effect that "successful vaccination" means vaccination proven by the characteristic mark of vaccination on the skin, that nothing else would be proof of successful vaccination It is unquestionably true that the school board must accept the physician's certificate, and if the physician is willing to perjure himself I do not see what the board of health is to do except to proceed against the physician The physician is the one who is putting himself in a false position Now comes the question, is it worth while to prosecute physicians who undertake to avoid the law in that way? My belief is that the proportion of such physicians is so small that it would be a mistake to attempt it We do not want to start any agitation in the community which would lead to another attempt such as was made during the past session of the Legislature, when an attempt was made to defeat the vaccination clause of the law of 1895, but fortunately the law stands as before You can scarcely imagine how strong the appeal was Petitions came from all parts of the State through the efforts of the Anti Vaccination Society, and we do not want to give them any such chance again If boroughs and cities will enforce the law correctly there will be no trouble

Advantages of London in the Study of Smallpox and other Contagious Diseases—At the present time five of the admirable hospitals of the London authorities, the Eastern at Homerton, the Western at Fulham, the South Eastern at Deptford, the South-Western at Stockwell, and the North Western at Hampstead, are open to students and medical practitioners, while instruction in smallpox is also afforded at the smallpox ships in the Long Reach, near Dartford A student desirous of taking a course at one of the hospitals must have completed his third year and have held the offices of clinical clerk and dresser, he must then obtain the sanction of the medical school to which he belongs and pay a fee of three guineas for the first three months, and one guinea for each subsequent month, to the clerk of the board, from whom he receives a card indicating the hospital to which he is to be attached At this hospital he must attend at stated times for at least two days in the week for a minimum period of two months, and on the completion of his attendance he receives a certificate from the medical superintendent whose lectures and classes he has attended While in the hospital the student places himself under the the control of the medical superintendent, and is bound to observe the regulations in force for the prevention of spread of infection These rules comprise the wearing, while within the hospital wards, of brown holland overalls, consisting of coat, trousers, and cap, which are provided by the board, and the use of what may be termed a discharge block, which consists of an infected room where the overalls are left, a lavatory, and a theoretically uninfected room The students are further required to keep their hair short and to be efficiently protected affainst smallpox A duly qualified medical practitioner has equally to conform to these regulations and must obtain the consent of the medical superintendent of the hospital at which he elects to attend The student who attends these courses will obtain a fair knowledge of infectious disease, which will stand him in good stead in years to come, while he will also get an insight into the management of fever hospitals and the methods of disinfection practiced therein The provisions with regard to instruction in smallpox differ somewhat from the above, as it is necessary for the student to reside for two weeks or upward on the smallpox ships, where he is provided with rations, apartments, and washing at an extremely moderate sum The student has to travel to and from the hospital ships on the ambulance steamer and to furnish himself with a suit of clothes to which he does not attach much value, in order that it may be disinfected or destroyed at the termination of the period

Another So Called "Water Famine" in London—The situation in the district supplied by the companies that deliver water to the northeast of London, has not altered for the better during the latter part of August and the early part of September, for the heavens still refuse rain [illegible] materially for the worse and that the public health remains fair must be looked upon as a piece of good fortune for the company, commensurate at least with the bad fortune which they are experiencing in running short of water during a drought For if an epidemic of any kind should break out in northeast London the medical men would have hard work to keep the mischief under when deprived of the most natural and efficacious remedy against zymotic diseases, water Proceedings are now being taken to place the mains of the company in communication direct or indirect with those of the other companies, and when this has been done all fear of an absolute water famine will be at an end But with the tiding over of the temporary difficulty we hope that the occurrence of these annual breakdowns will not pass from the recollection of the people of London They ought not to occur, and if the company can not prevent them the company would appear to be unable to carry on its business There is an alternative It may be said that the company can manage its works at least as well as any municipal or central body would be able to manage them, but that if there is no water it can not be supplied In this way the relations during the last two or three summers of the East London Waterworks Company with their clients form a strong argument for the augmentation or alteration of the present source of the metropolitan water supply It is said that in East London two million people now have their water supply only four hours a day at the most "We do not wish to inspire alarm, but if the present abnormal condition of meteorologic things continues, the consequences may be most serious The rivers are depleted to the utmost The drains are not adequately flushed and there is little flow in the upper reaches of the city to carry off the daily discharge of sewage," says the *Lancet*, and points out the necessity, if disaster is to be warded off in the future, of seeking new and adequate sources of water supply It argues that this supply must come from Wales As an illustration of its argument the *Lancet* mentions Loch Katrine in Scotland, which is now lower than it has been in seventeen years The depreciation in its water level is now about ten inches, and yet it is still an unfailing source of supply for Glasgow "It is a similar source of supply," says the *Lancet*, "to which, in view of the present conditions, London must turn, though not so favorably situated as Glasgow in this respect There is, however, the wonderful and inexhaustible watershed of Wales to which we may turn "

BOOK NOTICES

Manual of the New York County Medical Association Cloth Pp 60 New York Geo L Goodman & Co , 1898

This, the 1898 edition of the "Manual," contains the revised by laws as adopted May 16, 1898, and the "Code of Ethics" of the AMERICAN MEDICAL ASSOCIATION, with list of members

Michigan a Summer and Health Resort State By ROBERTS P HUDSON Paper Illustrated Pp 142 Lansing 1898 Robert Smith Printing Co , State Printers

This volume was compiled under the direction of the Michigan State Board of Health and "issued in compliance with a concurrent resolution of the legislature " It is gotten up on excellent paper, and contains many excellent illustrations of Michigan resorts, etc , in colors

Bulletin of the Harvard Medical Alumni Association No 12 Paper Pp 64 Boston Published by the Association, 1898

The "Bulletin" contains a report of the eighth annual meeting, held in Boston, June 28, 1898, officers of the association, constitution, address by the president, report of the committee on the medical school, etc It is on excellent paper and the presswork likewise excellent

Transactions of the Michigan State Medical Society Vol xxii Cloth Illustrated, pp 452 Published by the Society, 1898

These "Transactions" are for the thirty third annual meeting at Detroit, May 5 and 6, 1898 The papers presented at the session and included in the volume are grouped under the heads of "Septic Diseases of the Abdomen and Pelvis," "Obstetrics and Gynecology," "General Medicine," "Surgery and Ophthalmology " Under the first heading are papers on "Etiology," "The Blood," "Septic Infection of the Peritoneal Cavity, its Diagnosis and Treatment from a Medical Standpoint " "The Medical Treatment of Septic Peritonitis," "The Treatment of Septic Diseases of the Pelvis," "The Haughey Suture " Other papers are "Bottini's Operation," "Nephrectomy," "May a Rapid Pulse in Appendicitis Contraindicate Operation?" "Reflections on the Treatment of Appendicitis " "The Frequency, Causes and Prevention of Post operative Ventral Hernia," "Transillumination of the Stomach with Demonstration on the Person," 'The Four Tonsils," "Practical Value of Diagnosis of Presentation in Instrumental Delivery," "Some Anomalies of the Kidneys," "Kraurasis Vulvæ," "Physical Training an Essential Factor in the Radical Curative Treatment of the Pelvic Disorders of Women," etc

Transactions of the South Carolina Medical Association Paper Pp 262 Charleston 1898

The forty eighth annual meeting of the society was held at Harris Lithia Springs, April 13 and 14, 1898, and the papers presented at that session are included in this volume The following reports contain much of value On Obstetrics, on Ophthalmology, on Laryngology and Otology, and on Practice of Medicine The papers number twenty three The are also various reports of committees, list of presidents and meeting places for the last decade, officers for 1898-99, besides the minutes of the annual session and memorial notices of Drs Charles Rhett Taber, Oliver Miller Doyle, William Joseph Garner, Alex N Talley, Thos Jefferson McKie and Cornelius Kollock

Transactions of the Maine Medical Association 1898 Vol xiii Part 1 Paper Pp 240 Portland 1898

This volume of transactions covers the fifty sixth annual meeting held in Portland, June 1-3, 1898 The following papers are included in the volume President's Address, "Iatro Theurgic Symbolism" , "The Local Treatment of Sinuses of the Extremities" , "Accident as a Cause of Appendicitis" , ' Cæsarian Section on Account of Cyst of Ovary" , "Tuberculous Bone Disease" , "Talipes Equino Varus, with Report of a Case Successfully Treated by Cuneiform Osteotomy" , "The Treatment of Uterine Displacement" , "Myxedema as a Form of Anemia" , "Treatment of Diabetes Mellitus" , "Management of Epidemics of Diphtheria in Isolated Communities" , "Notes on a First Series of Ten Thousand Eye Patients in Private Practice" , "Relation of Medical Experts to the Courts and to Each Other" , "Necessity of Additional Hospital Accommodations for the Insane" , "Unusual Sized Rhinolith Removed with the Lithotrite, etc " , "Anastomosis of Gall Bladder with Large Intestine by Means of the Murphy Button" , "Case of Cerebro Spinal Meningitis, with Extraordinary Range of Temperature "

SOCIETY NEWS

Wyoming Medical Society—The next meeting of the State society will be held at Rock Springs, Wyo, Nov 1, 1898

The Erie Railroad Surgeons' Association—This association will hold its annual session at the Grand Pacific Hotel, Chicago, Oct 19 21, 1898 W W Appley, M D, Cochecton, N Y, is secretary and treasurer of the association

Railroad Surgeons' Meeting—The Association of Surgeons to the Pennsylvania Company West of Pittsburg will hold its annual meeting in Cleveland, Ohio, October 11 E C Brush of Zanesville, Ohio, is President and G B Stemen of Ft Wayne, Ind, secretary

New York State Medical Association—The Committee of Arrangements has secured a reduction in railroad fare from the Trunk Line Association, of one and one third fares for the round trip, to members of the association and their families visiting New York at the time of the meeting, October 18, 19 and 20, provided that 100 persons who pay full first class fare of 75 cents, or upward, coming to the meeting avail themselves of this privilege To make this reduction effective, certificates must be obtained from the ticket agent at the starting point, or nearest station issuing through tickets to place of meeting This certificate, to be valid for the reduction on the return fare, must be endorsed by the chairman of the Committee of Arrangements, and *vised* by a special agent of the Trunk Line Association, who will be present at the place of meeting for that purpose on October 19 and 20 The committee has also completed arrangements for a banquet at the Manhattan Hotel, Madison Avenue and Forty second Street, which will take place on the evening of October 19 F H Wiggin, M D, Chairman Committee of Arrangements

Wayne County Medical Society—At the regular meeting of this society, September 29, Dr D H O'Donnell read a paper on "The Physical Development of Girls" The Doctor treated the subject from the standpoint of the reformer He first enumerated the many defects of the body in womankind as it is today, making comparison of the average young woman in our cities with the strong, vigorous, well developed Venuses of olden time and laid the blame to such factors as fashion, ambition, giddiness of youth, faults in our schools and colleges, inattention and lack of interest on the parents' part, ignorance of laws of health, depravity of morals in young girls, ill fitting and useless clothing, fadism, etc The down trodden corset came in for its share of the rebuke which the Doctor administered to these evils He described it as the straight, stiff, well ribbed coat of mail worn by many women next the body and drawn recklessly close around the stomach and liver The Doctor described the ideal woman as the companion and equal of man, a creature of beauty, amiability and goodness, fully equal to the duties of maternity without undue pain or discomfort—the domestic goddess—at once a Venus and a Hebe The avenue to this lay through the efforts of the physician in his advice to the parents, giving them the most enlightning rules for the proper physical development of their girls and boys As heredity plays an important part in a girl's career, both her father and mother should be healthy and well developed, they should have no enervating or corrupting habits or surroundings, and the whole conduct of their lives should be well ordered and temperate An advance in this direction should be made all along the line by the medical advisers and family physicians Doctors should set the example by bringing up their own girls and boys with a rigid regard to their moral and physical well being, and nothing should be neglected to make the standard of true, pure womanhood the brightest and holiest thing on earth

NECROLOGY

Benjamin M Griffith, M D, St Louis (Mo) Medical College, 1859, died in Springfield, Ill, where he resided, September 24, aged 67 years He was a native of Shelby County, Ky, and a well known sanitarian, having served several years on the Illinois State Board of Health He was indentified with the American Medical Association and many other general medical societies His was a record of the greatest activity

George W Lindheim, M, D, assistant surgeon of the 8th N Y Volunteer Infantry, died at his home in New York City, September 16, of typhoid fever He was in charge of a hospital train which brought sick soldiers of his regiment from Chickamauga none of whom save Dr Lindheim himself have died up to the date of his funeral

Dietrich Nasse, M D, of Bergman's clinic at the Berlin University lost his life in the Alps by the giving away of a snow bridge, during the week ending September 17

John F Isom, M D, Western Reserve University, Cleveland, Ohio, 1877, and a resident of that city, died of cardiac disease, September 26, aged 67 years

Winthrop B Hallock, M D, Long Island Hospital College 1864, of Cromwell, Ct, died from apoplexy in a New York hotel, September 24, aged 65 years He left a wife and two children

John W Detwiller, M D University of Pennsylvania, 1873 died at Newport, R I, September 26 aged 47 years Until about two years ago he resided in Bethlehem Pa, and had been located in Newport only a few months His death was due to appendicitis a week after operation

Giovanni Trojani, M D, an assistant medical inspector of the Board of Health, Philadelphia, died September 26, aged [illegible] years Dr Trojani was graduated from the University of Naples, Italy, in 1881

F A Todd, M D, Toledo, Ohio, assistant superintendent of the Ohio State Hospital for Insane died at the Presbyterian

Hospital, Chicago, September 30, the result of a bite from a rabid dog He was 33 years of age

C D Manning, M D, Chicago, Rush Medical College, 1870, was killed while riding on a street car, September 24, in collision with a wagon Dr Manning was born in Dixon, Ill, in 1848

W E Fowlkes, M D, Owensboro, Ky, a graduate of the Louisville Medical College and also of Bellevue Hospital College, died at his home September 25, aged 50 years

J V Harmon, M D, Secretary of the Trumbull County Medical Society, died at his home in Warren, Ohio, September 18

M A Bacon, M D, Salem, Wis, September 24, aged 54 years ——Judson Brooking, M D, Athos, Va, September 20 ——John R Chappell, M D, Petersburg, Va, September 26, aged 70 years——Thomas R Clement, M D, Osterville, Mass, September 24, aged 75 years ——Julius W Cox, M D, Mapleton, Iowa, September 8, while on a hunting trip in Idaho —— J A Douglass, M D, Center Star, Ala, September 22 ——W P Griffiths, M D, Townanda, Pa, September 21, of rheumatism of the heart ——B N Herring, M D, Decatur, Ga, formerly of Clarksville, Tenn, September 19, aged 76 years —— Thomas Snodgrass, M D, Crossville, Tenn September 22, aged 76 years ——W H Sykes, M D, Plymouth, Ohio, September 20

MISCELLANY

Personal—Dr J C Minor, late surgeon, U S V, has resumed practice at Hot Springs, Ark

Correction—In the Journal for September 10, page 605, column one, in the title of Professor Landenzy's article, read "serum and toxin" for "serumated toxin", in column two, line 56, read "beef serum" for "beer serum"

Closing the Drug Stores on Sunday—The druggists of Bordeaux, France, have entered into an agreement to close all drug stores Sunday at noon, with the exception of one in each district The closed stores indicate the address of the one still open and the papers are also asked to give the address, without mentioning the proprietor's name The drug stores are to remain open in turn —*Bull de la Soc de Pharm de Bordeaux*, August

Tests for Standardizing Toxins—It is announced from Behring's Experimental Institute that animals react much more sensitively to intracerebral than to subcutaneous or intraperitoneal injections, and hence tests made with fluids introduced directly into the brain are much more delicate and reliable Guinea pigs will die from 1/60 of the usual fatal dose, and a tuberculous animal from 1/500 or 1/1000 —*Deutsche Med Woch*, September 15

Malaria Perniciosa Tetanica.—A Russian exchange reports a case Patient unconscious, rectal temperature 37 5 degrees C, reactionless dilated pupils, jaws clenched, muscle mass, like a board, and every group of muscles except those of the back and respiration in tonic contraction, spleen enlarged, heart and lungs normal As the patient came from Batum, where malarial infection is known to produce the strangest manifestations, he was treated with subcutaneous injections of quin bimuriat, carbamidat 2 0 in aq dest 4 10, which promptly cured him —*St Pet Med Woch*, September 4

Urine of Healthy Children—Churchill (*Archives of Pediatrics*, September) reports results in detail from an examination of 146 specimens taken from seventy children from 1 day to 12 years old His records show three points of interest the small amount of urine, the high percentage of urea, and the high specific gravity, i e, comparatively concentrated urine, and he raises a query as to whether the results represent a coincidence, or whether Americans do pass less urine in health and the probable later renal trouble from the constant irritation of the kidney

Duty of Person Bitten by Vicious Dog—Where a person was bitten by a vicious dog, through the alleged negligence of another person, from whom the former seeks to recover damages, the court of civil appeals of Texas holds, Trinity & Sabine Railway Company vs O'Brien, it became the duty of the person bitten to have taken such care of her wounds as a reasonably prudent person would have employed under like circumstances, and she can recover such damages only as she would have sustained if she had taken such care, and not for increased injury attributable to want thereof Negligence which allows damages to accumulate, the court continues, is not, like that which helps to cause the injury, a complete bar to recovery It simply prevents the recovery of damages which proper care would have averted

A Vegetarian Orphan Asylum—The late Professor Baron bequeathed to the city of Berlin money to found an orphan asylum, with the conditions that no physician was ever to be appointed on the Board, and vegetarian principles were to be strictly observed The mayor accepted the bequest, but the city council, which includes Virchow, Furbringer Fraenkel, Strassmann, and Renvers, has interfered, and the legacy will probably be declined, as the city authorities are unwilling to accept a bequest which compels them to submit orphan children to the experiment of a vegetarian diet

Operations for Goiter at Berne—Kocher's method is described in detail in the *Rev de Chir*, No 4 It never leads to hemorrhage, avoids injuring any nerve, and retains a portion of sound thyroid tissue, while the cosmetic results are fine and the wound heals by primary union without relapses The 204 operations described include 159 thyroidectomies, 12 enucleations, 19 resections, 16 enucleations and resections, and 2 ligatures of the large thyroid arteries Kocher only enucleates unilocular goiter cysts, easily shelled out nodules, or large nodules in immovable goiters, while he performs thyroidectomy in all other cases, including those of acute and chronic strumitis, and considers exothyropexy only justified when the operation has to be performed without the necessary instruments He has obtained good results in morbus Basedowii by ligating the third thyroid artery, followed later by ligature of the fourth

The Eyesight in the Open Air—Prof H Cohn asserts that examinations of the eyes in doors is no test of their actual capacity, and that all examinations of the eyes of school children, etc, should be made out of doors, as otherwise there can be no true standards He states that the superior visual acuity of Indians and other savages, is due to the necessity of concentrating their attention on objects on which their food and safety depend, and proves his assertions by statistics—many new and personal—which demonstrate that the *out of door* eyesight of civilized peoples averages as high as that of the uncivilized He concludes that any one can make his eyesight equal to that of a savage by concentrating his attention sufficiently He adds a plea for more out of door life for children, even at the expense of their studies, and training in closer observation —*Revue Gen d'Ophthalmologie*, August 31

Fibrils in the Nerve Cell—Golgi's latest preparations, exhibited before the Societa Med Chir of Pavia, showed clearly the delicate fibrillary arrangement and network in the Perkinje cells of the cerebellum and of other groups of ganglion cells of the central nervous system The fibrils are very distinct toward the periphery of the cell, but grow smaller toward the interior, and after a perceptible enlargement they penetrate into and blend with the innermost strata of the body of the cell The fibrillary apparatus differs with the age of the animal (cats, rabbits, dogs, horned animals and pigs) In the new born this fibrillary apparatus is much less complicated, the network much less evident In the adult animal the fibrils are more delicate, the network more distinct, the nodular enlargements more pronounced and the apparatus as a whole encroaches more upon the body of the cell. Golgi's report enhances the interest of Ewing's and Nissl's communications (JOURNAL, pages 131 and 674).—*Gazzetta degli Osp. e delle Clin.*, August 14.

Cæsarian Operations.—The number of these operations is increasing as asepsis enables the indications to be extended. Leopold and Haake report 100 in the *Arch. f. Gyn.* (lvi, 1), with 10 deaths, all very difficult and desperate cases. The conservative Cæsarian operation was performed 71 times, all the children taken alive, but two died later from the results of the operation, the Porro 29 times with two dead fetuses. They consider a conjugata vera less than 6 cm. an absolute indication for the Cæsarian operation, and amputate the uterus when the patient is debilitated by a serious disease, when there is reason to suppose it is infected, and when there is complete inertia or insufficient pains. Gonorrheal infection, a malignant tumor or ruptured uterus render the conservative operation impossible.

Ambulance Legislation.—Every now and then the ambulance surgeon gets his bitter dose of rebuke in the police court or in the newspaper. He is sometimes at fault, but more often he is the scape goat. In New York State, some wiseacre legislator has had a law enacted that is designed to deprive the ambulance surgeon of all discretionary power in the removal of the alleged sick or injured person. The law was passed in 1896, but it has not been generally known or enforced. A legal officer of that city is reported to have said that, in his opinion, need exists for such legislation and that the act "to insure prompt medical treatment for the sick or injured" is a most beneficent one, and should receive the cordial co operation of all our citizens. This law makes it a misdemeanor for any person in charge of an ambulance, hospital or house or place of reception for the sick or injured, which shall be wholly or partly supported at the public expense, to refuse to answer to a call or demand for an ambulance, or to take the person for whom the call may be made to the hospital or place of reception for the sick or injured from which the ambulance came, for examination and treatment by the house authorities of the hospital or place of reception. The act applies to the drivers of ambulances as well as to the physicians, and the penalty for its infringement is a fine not to exceed $500 or imprisonment for not more than one yaar, or both fine and imprisonment. If the act is enforced (it will probably not be) the various city institutions will have a very arduous duty procuring competent officers to operate their "little wards on wheels."

The Abuse of Alcohol.—Prof. Krapelin described the results of his recent research in regard to the effect of alcohol, at the annual meeting of the German Society against the abuse of alcohol. His conclusions explain the peculiar phenomenon noted by Exner in 1773, that when a person under the influence of alcohol is ordered to perform a certain movement, determined beforehand, following a certain external stimulus, he thinks that he performs it easily and promptly, while scientific measurement of the time elapsing between the stimulus and the movement proves a considerable delay in the response. Krapelin finds: 1, that the perception of impressions received by the senses is much retarded by the influence of alcohol, even a small amount, ¼–½ liter beer, will suffice for this. 2, the combination of ideas is much slower, processes of thought are altered, speech becomes more and more prominent, "thought spreads out in a level," 3, the voluntary movements occur much more easily and rapidly. This explains the contradiction between the objective record and the subjective impression in Exner's tests, the movement occurred more readily and rapidly, but time had elapsed before the stimulus was perceived. Observation in everyday life shows the correctness of these scientific data. The effect of alcohol on the psyche lasts more than twenty four hours, often several days. Leixner accused the medical profession of the responsibility for the spread of the use of alcohol, and others observed that there is more adulteration and fraud in the so called tonics and invigorating alcoholic beverages sold than in any other class of goods. Much amusement was caused by the arraignment of several members of the Congress for having imbibed a few "tenths" of beer with their lunch, which led to a clearer statement of the purpose of the Congress: to combat the *abuse* of alcoholic drinks, although Krapelin's research has converted him to "total abstinence."—From report in *Deutsche Med. Woch.*, September 15.

Medicine now in Disrepute.—An editorial of the *American Medico Surgical Bulletin*, Sept. 25, 1898, is justly caustic on certain usages of the times. The reflections upon "the yellow journals and their willing medical tools," are to the point, and the medico political critic, virtuously indignant for a purpose, shares deservedly in the animadversions. There are many hints of loose charges for the sake of a notice through the daily press and some looks askance at sensation mongers, but as no remedy is proposed, the profession at large must take its chances of survival. "Before the present war," says the writer "the newspapers were filled with glowing reports of the wonderful things medical science is capable of doing. Exaggerated accounts of our prowess were copied from journal to journal and the hospital surgeons and dispensary doctors were eulogized in glowing headlines, surmounted by their photographs. Now we are all in for condemnation, whether we had anything to do with the army or were mere stay at homes." *Sic transit gloria mundi.*

Can Exhibit Actual Condition.—Although it pronounces it an irregularity, the supreme court of Wisconsin holds, in the recent personal injury case of Selleck vs. the City of Janesville, that it was not reversible error for the judge and jury, the latter in charge of the sheriff, to go to the plaintiff's house, a distance of more than fifteen miles from the county seat, so that the plaintiff, who was carried into their presence upon a lounge and was administered to by her physician, could be sworn and testify as a witness in her own behalf. Following this up, the supreme court says that it perceives no error in allowing the plaintiff to exhibit her actual condition to the jury, nor in allowing her daughter to weep. It also holds that the following charge is supported by authority as well as reason: "The plaintiff is not held responsible for the errors or mistakes of a physician or surgeon in treating an injury received by a defect in the street or sidewalk, providing she exercises ordinary care in procuring the services of such physician. Where one is injured by the negligence of another, or by negligence of a town or city, if her damages have not been increased by her own subsequent want of ordinary care she will be entitled to recover in consequence of wrong done, and the full extent of damage, although the physician that she employed omitted to employ the remedies most approved in similar cases, and by reason thereof the damage of the injured party was not diminished as much as it otherwise should have been." The wrongdoer, the supreme court says, may well anticipate that the person injured will employ a physician or surgeon, and in doing so will exercise ordinary care in making the selection, but, where that is done, such person can not be expected to assume the responsibility of the very highest degree of skill. Indeed, it calls attention to the fact that it has gone so far as to hold that where personal injuries result proximately from negligence or other tort the wrongdoer is liable for the damages actually sustained although they are increased by a tendency to disease on the part of the person injured.

Effect of Altitude on Anemia.—According to the *British Medical Journal* Paul Bert as early as 1882 called attention to the fact that the blood of an animal on a mountain absorbs more oxygen than under lower conditions. Mercier and others ha found that while counting the corpuscles of men and rabbits returned from the mountains to the plains, the daily decrease ceased on the thermometer falling 13 mm., and in two rabbits there was even an increase of corpuscles. Whether on a mountain or under a bell jar, the most noticeable alteration in the blood is an increase of the red corpuscles, which appears earlier and is more rapid than the increase of hemoglobin. Egger has had the same results in man at an elevation of 1890 meters; the average increase of red corpuscles after fifteen days was 16 per cent. Mercier confirms this. Those observers (Loewy and Kohlbrugge) who have failed to note this property of mountain air were not careful to exclude vitiating conditions from their experiments. All the most reliable evidence goes to show that the increase of red corpuscles is real, and has nothing to do with a supposed concentration of the serum through evaporation. Viault and others have remarked the great number of small discs in blood received on elevated places, which are probably developing erthrocytes. This explains the fact that hemoglobin does not increase so rapidly as the corpuscles, since the young globules do not contain their full amount. Finally Schauman and Rosenquist have observed nucleated red corpuscles in the blood of dogs and rabbits living for some weeks under a bell jar under a depression of 45 to 48 cm. of mercury. Suter and Jaquet found that in rabbits which had lived at Davor for four weeks not only was their blood one sixth richer in hemoglobin than that of those left behind at Basle, but the quantity was more per kilogram of body weight (about one tenth). The mechanism of the increase of red corpuscles is still not properly understood. It is certain that in healthy persons the increase is not permanent, but disappears on a return to the plains as rapidly as it came. However, the most important fact is that anemic people retain more red corpuscles than they had before their mountain sojourn for long after their return.

Creasote in Gastric Affections.—According to Zanger of Zurich, in a paper on creasote, contributed to the *Correspondenzblatt für Schweizerische Aerzte*, the present tendency to think that the larger the dose of this drug the better in phthisical cases, is by no means justified by experience, for the best results are often obtained with very small doses indeed. He believes that their beneficial effect is due to their action on the stomach, causing it to do its work better, and so to improve the nourishment of the system. He finds that in many cases of purely gastric affections, with or without diarrhea, or other intestinal symptoms, minute doses of creasote will often succeed when other remedies have failed. In the gastroenteritis of children and in the vomiting of pregnancy, he has been greatly struck with its effects. The doses he gives vary from 1/11 gr. in children to 1/3 gr. in adults. He prescribes it with enough spirit to dissolve it in a spoonful of water, with or without water. Black coffee or mint tea may be employed, if necessary, to disguise the taste. When infantile diarrhea exists, without vomiting, he has often found creasote valuable. In the milder forms of the vomiting of pregnancy small doses of creasote have always produced an improvement, and he thinks that even in severe cases a trial of the same treatment should be made.—*Public Health*, August.

Syphilis and Divorce.—There are two recent decisions on this subject that should be noted. In the case of Smith vs. Smith, the supreme judicial court of Massachusetts holds, that where a wife ascertains, within a short time after the performance of the marriage ceremony, and before the consummation of the marriage, that her husband has syphilis, which has advanced to such a stage as to be probably incurable, whether he acquired it through unchastity or has become constitutionally affected with the disease from his birth, she is entitled after refusing to consummate the marriage, to have it annulled. Few, if any, says the court, would be bold enough to say that it was her duty, on discovery of the fraud, before consummation of the marriage, to give herself up as a sacrifice, and to become a party to the transmission of such a disease to her posterity. There are reasons why a fraud of this character, discovered before the consummation of the marriage, and at once made a ground for separation, should move the court more strongly in favor of the wife than if the discovery had come later. And the court takes particular pains to state that it does not intimate that the concealed existence of venereal disease in one of the parties to a marriage will ordinarily be a sufficient ground for a decree of nullity. In most cases, presumably, it significantly remarks, the disease is curable. The other decision referred to is one of the supreme court of Pennsylvania, rendered July 21, 1898, in the case of McMahen vs. McMahen. Here was a case of a young woman, whose innocence was not at all impeached, having been infected with syphilis by her lover (who subsequently became her husband) during the period of his courtship, probably by kissing her frequently, and after marriage having been kept constantly in a diseased condition from the same source, until she had passed into the secondary condition of the disease, and had approached on the tertiary stage thereof, having endured for upward of five years the constant presence of one of the vilest, most shocking and dangerous diseases with which the human body can be afflicted. Is such a person legally bound to remain in such relation with her husband during the whole of her subsequent life, and has she no redress whatever, in the way of divorce? asks the court. But it says that, in its opinion, to state this question is to answer it. It says that it does not see how it is possible to imagine a more direct and palpable case of cruelty to a wife by her husband than this, and that it comes within, not only the spirit, but the very letter of the Pennsylvania statute which allows divorce "when any husband shall have by cruel and barbarous treatment endangered his wife's life, or offered such indignities to her person as to render her condition intolerable and life burdensome, and thereby force her to withdraw from his house and family." It is of no consequence, continues this court, that inoculation occurred before marriage. It is the continuation and constant presence of the disease after marriage, making her condition intolerable, and endangering her health and life, that entitles her to a divorce.

A Child can not Maintain an Action for Injuries Sustained Before its Birth.—The appellate court of Illinois, first district, holds on appeal in the case of Allaire vs. the St. Luke's Hospital, May 26, 1898, that the action not being given by any statute, a child can not maintain one, by the common law, for injuries sustained before its birth. That a child before its birth is, in fact, a part of the mother, and is only severed from her at birth, can not, the court thinks, be successfully disputed. The doctrine of civil law and the ecclesiastic and admiralty courts, that an unborn child may be regarded as in being for some purposes, when for its benefit, the court pronounces a mere legal fiction, which, so far as it has been able to discover, has not been indulged in by the courts of the common law to the extent of allowing an action by an infant for injuries sustained before its birth. If the action could be maintained, it would necessarily follow that an infant might maintain an action against its own mother for injuries occasioned by the neglect of the mother while pregnant with it. Mr. Justice Windes dissents. He argues that if the willful and malicious conduct of a person causing an injury to an unborn child resulting in its death after it has been born alive, will fasten on the person the crime of murder or manslaughter, there seems no sound and logical reason, since the crime includes the injury to the child, and since the public offense is also a private and special wrong to the helpless infant, why, if the child should be so fortunate as to survive the injury, which, had it caused death after being born alive, would have made the wrong doer a criminal before the law, the child should not have his action at law against this same wrong doer, for damages because of his tort Could it be successfully contended that for an injury to Chang, one of the famous Siamese twins, he could not maintain an action because he was a part of his brother Eng—that he was not a separate entity? Could it be contended that in such a case Eng was the person to bring the suit, because the injury to his brother Chang was an injury to him, Eng? The judge thinks it quite as reasonable to say that the mother can recover for injuries to her living moving child because contained in her womb or lying beside her after its birth, attached by the umbilical cord as to say that in the case of an injury to one of the Siamese twins, the other could have brought suit The child, when capable of being born alive, is in the judge's opinion, a distinct entity, under the common law, and although no distinct civil case, so far as he knows, has so held, humanity and enlightened civilization, he insists, demand that the common law as administered in Illinois in the 19th century should so declare What will a still higher tribunal say if called on for a decision on this point?

Behring's American Patent on Antitoxin—The *Munich Medicinische Wochenschrift* of September 6, contains the following editorial "Professor Behring of Marburg has at last, after a number of ineffectual attempts, succeeded in obtaining a patent in the United States for the production of diphtheria serum The patenting of a scientific discovery by a physician contradicts to such an extent the cherished traditions of the medical profession that it is not surprising that Professor Behring has been assailed with violent criticisms on account of this patent He replies to these criticisms in the following explanatory letter which has appeared in a Marburg paper 'It is true that a patent has been granted me in America for the production of diphtheria serum, and it is true that the American firms who have hitherto been commercially benefitting by the production of diphtheria serum are angry about it When the Americans interested express their anger in the American way, that is their own concern, but when in this case, entirely contrary to their usual customs, they declare that to take advantage of existing laws to exploit an important practical discovery, is immoral and scandalous, I can not accept their verdict seriously For my part, I do not consider a legitimate means of making money dishonorable I might even go so far as to say that I consider the renunciation of a considerable pecuniary profit, legitimately one's own, unpardonable folly Time will show whether the American courts will be coerced by this newspaper clamor into interfering If this, as I confidently anticipate, does not occur, then the American public will derive much benefit from the patent, as they will then secure the diphtheria serum better and cheaper The denial of my right of invention and discovery is based on ignorance and injustice Ask any one of the scientists whose names are mentioned as having co operated with me in the discovery of diphtheria serum, not one of them will wish to contest the priority with me' This explanation can only arouse the most painful sentiments in medical readers The last statement is correct To Behring alone belongs the honor of the glorious discovery of diphtheria serum But the gratitude which the world, and especially the medical profession, owe him for this discovery should not induce us to accept in silence such principles as are enounced in the foregoing explanation It is not true that every way of making money which does not conflict with the laws, is honorable for the physician It would be the severest blow to the prestige of the medical profession if these principles, which sound like a sneer at the efforts of physicians to raise themselves above the level of the trades, should be accepted As far as the patenting of a remedy is concerned, the German patent laws do not allow it, even the diphtheria serum is not protected in Germany This restriction does not seem to exist in America, altho [illegible] Code of Medical Ethics, endorsed by the better A physicians, declares that it is 'derogatory to professional character to hold a patent for any surgical instrument or medicine [illegible] inconsistent with beneficence and professional liberality' The American, as well as the English professional press, regard Behring's application for a patent as a breach of the ethical foundations of the medical profession, and criticise it in the severest terms, which we must regret all the more as we can not consider them unjustified "

Behring disclaims that he is still a physician In a letter to the *Deutsche Med Woch* of September 15 he remarks "I gave up my professional practice when I entered upon my career as an experimenter and inventor, and I am compelled to seek means in a commercial way to carry on my experimental therapeutic work "

Nerve Fatigue of School Children—Dr R C Scheidt, of the Franklin and Marshall College, presented a voluminous address (*Public Health*, July) on the hygiene of school attendance, before the fifth annual meeting of the Associated Sanitary Authorities of Pennsylvania (*vide* JOURNAL June 18, 1898, p 1469), in which he urged an ampler protection of the health of the overworked children of the public schools He argues against the afternoon session as being unnecessary confinement, if the pupils have a long and properly arranged morning session The following are some of his conclusions 1 I am convinced that the esthesiometer is the proper instrument for the measurement of fatigue 2 My tentative experiments with American boys prove a superior normal strength of their mental vigor under favorable conditions of the atmosphere 3 Unfavorable conditions of the atmosphere show an unusually large percentage of abnormal fatigue of the nervous system 4 I attribute this condition to the utter lack of systematic open air exercises 5 I advocate such exercises for children as a prime necessity, because the foundations of a healthy and useful life are laid between the seventh and fifteenth years, but never afterward 6 Training of all the functions of the physical organism should precede instruction, because it will develop the necessary mental strength 7 Children should be classified according to their individual characteristics, and stress should be laid upon the development of their weakest organs, in such a way, however, as to leave plenty of room for individualization 8 Such exercise should take place every afternoon, and should be continued until the limit of normal fatigue is reached 9 The exercises should be grouped into muscular, cutaneous and respiratory 10 All these exercises should be essentially exercises of the nervous system, to lead to a proper development of character The writer holds that it is not learning, primarily, but health and character should be the watchward of our schools first training, then instruction, the sequence of a rational educational policy Pedagogics, as a science, should therefore no longer be based upon philosophy, but upon physiology and hygiene The chief factor in every school board should be the well trained physician and the physician only His investigations, carried on for a number of years, have led him to the firm conviction that the American boy is the superior of the boy of any other nation on the face of the globe, he is worthy of special considerations because his training will in the end produce the superior man, for only during the years of boyhood, from the seventh to the fourteenth, fifteenth and sixteenth year, can training be made successful, if neglected then it will forever remain neglected Considering the large number of heterogeneous branches now taught in our public schools, and, at the same time, the intense interest in all sorts of ill directed physical exercises manifested by both girls and boys we conclude that the endurance for every specific activity can be but small, while the sum total of all the energies consumed is rather larger than in former ages, however, the mere [illegible] exhibition of ability is, in the case of children, [illegible] the absolute criterion for the sum total of l [illegible] hu [illegible] while in the process of growth, while digestion is going on Under unfavorable external conditions, abnormal fatigue will prevail throughout the whole afternoon, and in the course of time the brain will become unfit for mental work Afternoon instruction is therefore absolutely unhygienic Teachers are unanimous in pronouncing afternoon mental work a failure in the majority of cases One long morning session, with a number of recesses, ought to suffice Let that instruction be rational, let it largely be object teaching, do not overfeed children with grammar, which presupposes mastery of speech and the power of developed thought The brain cells required for such work are as yet but imperfectly developed, and the natural result is a mechanical memorizing resembling the training of a parrot How different the effect of the introduction of the various mechanical arts They appeal at once to the various organs of sense, and through them to the intellect Large playgrounds should be provided in every city, and every school house should be joined by a large roof covered area, equipped with the most important apparatus necessary for physical training, for both summer and winter The authorities ought to see to it as much as possible that each child is given the opportunity to develop its individual inclinations, for in the nature of the case, and necessarily so, class room work has a levelling tendency, its laws are those of a liberal sometimes even of an illiberal, despotism, a child becomes one of a dozen, and nothing more, and the only virtue practiced is that of obedience, which it should have acquired at home On the play ground the development of individuality ought to be given a chance, but always under the control of the wiser parent or teacher

Detroit

HEALTH REPORT for week ending September 30 Deaths, under 5 years, 36, births, male 33, female 32, diphtheria, 5 cases, 12 new cases, 4 recovered, 1 dead, 12 sick now, scarlet fever, 4 cases, 7 new cases, no recoveries, no deaths, 11 sick now, smallpox, 2 sick, 5 new cases, no recoveries, 7 sick now

Cincinnati

DR P S CONNER, of this city, has been appointed to the commission for the investigation of the war department Dr Conner was born in West Chester, Pa, in 1839, served with distinction as an assistant surgeon in the War of the Rebellion, but did not retire from service until 1866 Since leaving the Army he has practiced in Cincinnati He has been president of the American Surgical Association, the Ohio State Society, the Cincinnati Academy of Medicine, is Professor of Surgery in the Ohio Medical College and in the Dartmouth Medical College, and also surgeon to the Good Samaritan Hospital and, until a few years ago, to the Cincinnati Hospital

Louisville

HEALTH OFFICE —In the forthcoming annual report the Health Officer, Dr M K Allen, will urge the following recommendations A milk and food inspector, the establishment of public urinals, the establishment of public baths for the use of the poor, the setting apart of a hospital for the care of consumptives, the establishment of a detention ward at the City Hospital for persons suspected of being insane, and for the surgical treatment of patients from the work house and alms house, the furnishing of diphtheria antitoxin to the poor by the city, requiring all physicians to report the following diseases to the Health office, not to be placarded consumption, typhoid fever and whooping cough, and the placing along the thoroughfares baskets or boxes to be used as receptacles for waste paper, fruit peelings, etc

BOARD OF PHARMACY —Governor Bradley has appointed Mr Addison Dimmit a member of the State Board of Pharmacy, to succeed Dr J W Fowler, whose term had expired Mr Dimmit is a member of the firm of Geo A Newman & Co, whole sale and retail druggists of this city

MATHEWS —Dr J M Mathews has just returned from an extended trip east, having been in attendance upon the American Association of Obstetricians and Gynecologists at its recent meeting in Pittsburg

MORTALITY REPORT —The mortality report for the month of September shows a total of 230 deaths against 262 for the same month last year Consumption caused thirty eight deaths, typhoid fever eleven, old age thirteen Only sixty of the deaths were colored people

GILLETTE —Miss Nellie Gillette, who for five years has been the efficient Superintendent of the John N Norton Memorial Infirmary and Training School, has left for her home in New York on a year's leave of absence on account of ill health She will return at the end of that time to resume her duties A class of four will graduate this month from the Training School

Washington

HEALTH OF THE DISTRICT —The report of the Health Officer for the week ended September 24, shows the total number of deaths to have been 104, of which 52 were white and 52 colored The principal causes of death were nervous diseases, 12, circulatory, 8, genito urinary, 5, respiratory, 16, intestinal, 11 There were five deaths from typhoid, 7 from diphtheria and 3 from malaria There were 79 cases of diphtheria and 57 cases of scarlet fever under treatment at the close of the week There are no cases of smallpox in the city at present, the last case having been discharged from the isolation hospital on the 15th ult

HEALTH OFFICER AFTER FREEDMAN'S HOSPITAL —Health Officer Woodward has called upon the surgeon of the Freedman's Hospital for an explanation of the fact that the contagious disease regulations are being repeatedly violated by that hospital, in not properly caring for and reporting contagious diseases to the Health Office Dr Woodward has appealed to the Interior Department in order to secure its co operation in checking the reported violations If Congress would abolish the "political plum feature" of this hospital and place the control of the institution under the District Commissioners, where it rightly belongs, the existing friction would be promptly removed

CENTRAL DISPENSARY AND EMERGENCY HOSPITAL —The annual report of the Central Dispensary and Emergency Hospital for the year ended June 30, 1898, shows the total number of new patients treated was 11,927, making 35,333 visits, of this number 7722 patients were treated in the Dispensary and 4205 in the Emergency Department There were 2120 operations performed, 308 patients committed to the wards, 579 ambulance calls, 36,196 prescriptions compounded and 41 deaths Dr Burnett, the President of the Attending Staff, calls attention to the necessity for more room for the treatment of patients, and notes that there was a slight falling off of new patients in the dispensary during the year, due to the rigid enforcement by the hospital authorities of the rule of the Medical Association, requiring applicants for treatment to present a certificate of dependency before being admitted to the different services He also calls attention to the munificent gifts of Mrs Phebe A Hurst Last year she presented the hospital with a very valuable X ray apparatus, and this year she has presented a large plat of ground and house for the nurses of the hospital The work of the Ladies' Auxiliary Board, in improving the operating rooms of the hospital is highly commended, and the excellent work of the resident physicians specially noted The superintendent, Miss Simonton, reports that the training school, which has been started in conjunction with the Washington Asylum, the Washington Training School for Nurses and this hospital, is being conducted very satisfactorily, and a large number of pupil nurses have been admitted The treasurer's report shows the total receipts to have been $17,531 65, and the total expenses to have been $17,528 55, with a balance of $3 10

PHYSICIAN TO THE POOR APPOINTED —Dr James R Tuban, the faithful substitute physician to the poor, has been pro moted to fill the vacancy caused by the resignation of Dr J D Bradfield, physician to the eighth district

Army Appointments —Drs Edmund Barrie and Samuel N Hannon have been appointed acting assistant-surgeons in the Army The former leaves to take charge of the Red Cross Hospital at Camp Mead, the latter goes to Santiago de Cuba for special detail

Visited Washington —Dr Joseph M Matthews, President of the American Medical Association, and Dr I N Love of St Louis, made a flying visit to Washington on the 30th ult

Philadelphia

Another Infected Schoolhouse —A serious epidemic threatens the district of Paschalville, where thirteen cases of diphtheria have recently occurred, eleven of which can be traced to the John Bartram school An investigation of the throats of several children who had been ailing for a few days showed the presence of the specific germ In one instance in which several children from one family were suffering with diphtheria, it was found that there had been no physician in attendance, and on further inquiry it was learned that the family were Christian scientists It is stated that Dr Taylor of the Bureau of Health detailed a corps of medical inspectors to make a thorough investigation of the suspicious cases occurring in the district and report same to the proper authorities, and institute quarantine where necessary The schoolhouse has been thoroughly cleansed and fumigated

Appeal for Funds —Owing to the heavy drain necessarily entailed in bringing to this city and caring for a thousand sick soldiers, the National Relief Society of Philadelphia has made an urgent public appeal for funds in order to carry on its work It is not all to simply care for the soldiers while they remain in the hospitals, but the heaviest burdens will fall upon the families of those who have been discharged from the hospitals in shattered health and without any permanent employment It is stated that in some instances of this character, a few poor unfortunates have actually had to pawn their clothing before employment was found Mr George C Thomas, treasurer of the National Relief Commission, acknowledges the following contributions Cash previously acknowledged, $66,627 32, other contributions and supplies, $40,265 The Red Cross Society of Philadelphia has been very active in the relief of the sick soldiers, and up to date $14,888 14 has been received, which will go to those who most need support while seeking for permanent employment The hospitals of the city also receive contributions to be expended in this manner, and by the co operation of all channels it is hoped that every unfortunate patient brought here may be cared for and his wants attended to

University of Pennsylvania —Several familiar faces were missed at the opening exercises, and a touching tribute was paid to Dr William Pepper by Provost Harrison, who recited the wonderful advances made by the University under his direct guidance The venerable master of surgery, Dr John Ashhurst, was referred to with the heartfelt hope of his early recovery The University begins the session with much greater facilities for teaching, such as new laboratories, etc The lengthened course has not prevented an increase of numbers over the period when only a three years' course was required, and there are now more students enrolled up to the present time than there were last year

Personal Mention —Dr William White, professor of clinical surgery in the University of Pennsylvania, who has been spending the summer in Europe, has returned home to resume practice and clinical teaching at the University

Dr Benjamin Lee, Health Officer of Philadelphia who has been in attendance at the twenty sixth annual meeting of the American Public Health Association, has returned It is reported that at this meeting a resolution was passed favoring the appointment of a committee to secure the co operation of the United States, Canada, Mexico, and as far as possible the countries of Europe, to adopt the Bertillon system for the classification of diseases, on account of the inaccuracies of the other systems now in vogue Pennsylvania adopted the Bertillon system at the last meeting of the State Board of Health, and it is hoped that its results will prove both convenient and useful

Surgeon General W K Van Reypen, U S N, has recently made a thorough inspection of the naval hospital situated at this point, and pronounces the condition of things eminently satisfactory

Faculty Changes —Since the death of Dr William Pepper professor of the theory and practice of medicine at the University of Pennsylvania, there has been much speculation as to his successor Nothing was known of the action which the Board of Trustees might take toward choosing his successor, and while the Board recently placed Dr James Tyson in this coveted chair, it seems that this action is not entirely final, and Dr Tyson will only be the nominal head of that department, while the didactic lectures will be given by several capable teachers of the faculty The University has always conformed to the civil service reform by promoting those it has brought up into the places made vacant by the death of one of its members Dr Tyson will have full supervision over the branch of general medicine, both didactic and clinical, while Dr John H Musser, Dr Alfred Stengel, Dr M Howard Fussell and Dr Frederick A Packard will give didactic lectures to members of the graduating class The names of Dr Judson Daland and Dr John K Mitchell were also mentioned for this honor, but as they both now hold chairs in the teaching faculty, it was thought best not to make any changes in their departments Owing to the unfortunate illness of Dr John Ashhurst, his chair remains unfilled and will probably remain so during the coming term In the meantime, Dr J William White will be the nominal head with full supervision over the department, while Dr H R Wharton and Dr A C Wood will give some of the didactic lectures until final action is taken by the Board of Trustees

Ayer Laboratory —The foundation of the Ayer Laboratory has been laid and the building is now assuming definite proportions The building was given to the Pennsylvania Hospital by Mrs Josephine Ayer of Lowell, Mass, who left a legacy of $50,000 to the hospital for the erection of this building The material used will be red brick with gray granite, but the style of architecture of the simplest kind, with Doric pilasters and symmetric arrangement of the windows so as to maintain as much as possible the old colonial tastes The basement will be utilized as a museum, the first floor for autopsies and a mortuary chapel, the second floor for bacteriologic and chemic studies, and the attic for scientific photography The building will have an endowment of $25,000, so that the work in the different departments will never become embarrassed from the lack of funds

Woman's Medical College.—At the opening session of the Woman's Medical College of Philadelphia, Dr Gertrude Walker delivered an address dealing with the influences in and around the medical profession and pointing out to the students the evils to be avoided and urging a high preparatory course before beginning the pursuit of medicine In the opinion of the speaker a large proportion of the ills of humanity were due to hysteria, and from this source Christian scientists gained a foothold upon the community The speaker also warned the students against all forms of quackery and associations of "pathists" of every school A four years course has been instituted at this college

Another Wail from Homeopaths —From the recent meeting of the homeopaths of Pennsylvania, recently held in Pittsburg, comes a complaint of the unfair treatment accorded the Hahnemann by the innumerable officials of Philadelphia over the distribution of soldiers who were brought to the city for treatment, and it was thought the Hahnemann did not have a fair chance to get at them Dr Mohr is reported as saying "When the first train left Philadelphia to bring the sick soldiers from the South, we made application to the Director of Public Safety and other officials in the city, but although we stated that we could care for twenty five cases, we received only *one* When the second train left we still gave them the option of sending twenty five cases, but we received only "one" Fortunately, however, for us as a school and a hospital, we had placed *ourselves in communication with the* —— and from his representative in Philadelphia an aggregate of sixty two soldiers were received "

PRESIDENT OF WISTAR INSTITUTE —At a recent meeting of the Board of Trustees of the Wistar Institute of Anatomy and Biology, Provost Charles C Harrison of the University of Pennsylvania was elected president to succeed the late Dr William Pepper The Wistar Institute of Anatomy, while its work is, not fully comprehended, being for post graduate students only, will some day take first rank with any institution of its kind in America, for its endowment and large collection of anatomic specimens could hardly be duplicated on this side of the Atlantic The institution is governed by a board of managers, six of whom are elected by the trustees of the University

WOMAN'S HEALTH PROTECTIVE ASSOCIATION —This Association, which has taken such a prominent part in the crusade against the filthy Schuylkill water and is instrumental in bringing about reforms in hygiene among the poorer classes, recently had its first fall meeting The president, Mrs John Scribner, delivered an address outlining the work for the coming months, and stated that the principal subjects which would receive attention would be contagious diseases, meat, milk the schoolhouse question and the "consumptive poor "

SHAIN SCHOLARSHIP —As a result of a competitive examination held recently, Robert Sawford Scott was awarded the Shain scholarship in the Jefferson Medical College This scholarship was established from the legacy of Dr Francis W Shain, who bequeathed $4000 for this express purpose The scholarship entitles the recipient to a four years' course in the Jefferson Medical College, and as the examination is a rigid one makes the honor the greater

Societies

The following recent meetings are noted

Iowa —Northwestern Medical Association, Sac City, September 21

Maryland —Baltimore County Medical Association, Baltimore, September 22

Michigan —Kalamazoo Academy of Medicine, September 27

Missouri —St Louis Medical Society of Missouri, October 1, Medical Society of City Hospital Alumni, September 15

New York —Medical Society of the County of New York, New York, September 26, Syracuse Academy of Medicine, September 20

Ohio —Delaware County Medical Society, Delaware, Oct 4

Pennsylvania —Susquehanna County Medical Society, New Milford, October 4, Venango County Medical Society, Franklin, September 20

Tennessee —East Tennessee Medical Society, Newport, September 22

Texas —Houston District Medical Association, Sept 26

Wisconsin —Central Wisconsin Medical Society, La Crosse, September 27

American Public Health Association —This Association elected the following officers at the recent meeting President, George H Rohé of Baltimore, secretary, C O Probst of Columbus, Ohio, treasurer, Henry D Holton of Brattleboro, Vt, executive committee, Prof F C Robinson of Brunswick, Me, Irving H Watson of Concord, N H, Frank W Wright of New Haven Conn, and others The Association will meet in Annapolis in November, 1899 An abstract of the proceedings will appear in the JOURNAL, beginning next week

ADDRESS

THE EVOLUTION OF SPECIALISM IN MEDICINE

The Presidential Address delivered before the American Association of Obstetricians and Gynecologists, at Pittsburg Penn , Sept 21 1898

BY CHARLES A L REED, A M , M D
CINCINNATI, OHIO

Fellows of the American Association of Obstetricians and Gynecologists

In conforming to the custom which demands an address from your retiring president, I cheerfully and feelingly comply with that other usage which requires that my first expression, on this occasion, shall be one of profound gratitude for the honor conferred in electing me to preside over this, your eleventh annual convention

We have at this meeting entered upon the second decade of our organic existence The moment is opportune for a brief reflection upon the purpose which brings us into annual convention That that purpose is real and deep and earnest is shown by the fact that each of our reunions but serves to increase the enthusiastic devotion to work which has always characterized our proceedings From the day of the preliminary convention at Buffalo, April 19, 1888, to this moment, there has been no flagging in the task to which we, as a body, have set our hands—the task of broadening, deepening and refining those beneficent departments of the healing art embraced in the title of our organization To this congenial task we shall continue to devote the best energies of our nature But while our object and purpose is clear and distinct, it may be well for us to pause a moment and consider, in a somewhat philosophic way not only our present status, but those forces and conditions which brought us into existence and those influences which shall determine our destiny

It is safe to accept ourselves, in our organic form, as an integral part of a complex social fabric Social fabrics such as ours have their origin in primitive conditions from which they are evolved in conformity to established laws—laws which deal with matter and motion and force We can fancy that the starting point was a stable equilibrium, which, in fact, can be nothing more than a theoretic conception that marks the transition between growth and decay between life and death In the course of those changes which we recognize as developmental and progressive we are constantly confronted by phenomena which display on the one hand the persistence of immutable force, and on the other the diversion of that force into multitudinous channels through the instrumentality of resistent inertia The results are not only correspondingly multitudinous, but each result is susceptible of further segregation, in the course of proggession to final effects Thus, each division of initial force results in the changing of a uniform into a multiform force, while each separate form of the latter becomes itself a specialized force, susceptible of further subdivision It follows, therefore, that we must accept as a fundamental sociologic doctrine, based upon primary biologic law, that progress is due to the gradual evolution of heterogeneity This process is exemplified, not only in the complex social organisms, but in every phase of organic life The seed that drops into the soil speedily loses its homogeneous character in the process of germination, and, still further, in each successive change, until maturity is attained in shrub or tree or plant In the act of human reproduction, the same phenomena are exhibited in even more complex form in the mysteries of embryologic development and in the conditions of subsequent individual existence What is true of the individual members of the vegetal and animal kingdoms is still further manifested in the origin and development of species in those departments of nature The ultimate products are manifested in the complex flora and fauna that today entrance our naturalists in their efforts of analytic research

We find the lesson that best subserves our purpose exemplified in the initial changes which take place among the most primitive of peoples Let us take, for example, as suggested by Mr Spencer, a tribe of North American Indians Living as they do chiefly by the chase, an early necessity which they encounter is the means of killing their game, and let us say, each man provides himself with arrows for the purpose Presently one of the number, as the result of accidental influences or conditions, discovers that he can make better arrows than can his fellows They, in turn, desiring the best implements, go to him for their arrows, for which they compensate him with mats or baskets or fishing gear, while he, stimulated by reward and the distinction implied by patronage, restricts his labors to his new-found task improving his product in excellence with that increasing skill which comes alone from practice The influence is reciprocal, and its widening range is noticed in the improving quality of the mats and baskets and fishing gear made by those who find it no longer necessary to make their arrows Here is the multiplication of effects from an initial cause, and here too, we observe the commencing specialization of function and of labor exemplified among the most primitive of peoples What is true of these simple folk is true in a more pronounced degree throughout the increasing complexity of civilized society So true is this, that today there is not a single department of human activity there is not a single product of human labor, mental or physical, but is dependent for its possibility upon numerous other highly specialized human activities In the building of a house, how many special activities are exercised in forest in quarry, in kiln in factory and in the final act of construction, until the finished structure stands ready for the coming of its owner? In the construction of the stately bridges that span the three rivers that here mingle their tides, how many "specialists" have been engaged in the mine, the forge, the foundry and the coffer-dam? In making and operating the railroads over which you came hither with such comfort, safety and speed, how many "specialists" have been and are employed? The telegraph, the telephone, illuminating plants, and hydraulic institutions are but a few—a very few—other examples made possible only by employment of highly-specialized human skill. From these observations, we are forced to conclude, with that master-genius who has formulated with such clearness the philosophy of evolution, that a "part cause of evolution is the multiplication of effects, and that this increases in geometric progression as the heterogeneity becomes greater"—conclusions which are not only "established inductively but are deducible from the deepest of all truths."

But if primitive people required arrow-makers or the fabricants of other implements, other necessities speedily arose, chief among which was attendance on those who were injured in the chase, who were wounded in battle, or were sickened by the effluvia of the primeval swamps. It was at this point that your progenitor, "the medicine man," stepped upon the scene. He is the necessary and inevitable incident of every primitive people. The Egyptians had their sages, soothsayers, and *pastaphori*, the Persians had their *genii*, the Phœnicians their *cabiri*, the Hindoostanese their *vaidyas*, the Tartars, their *shamans*, the Scythians, their *cnares*, the people of Borneo and Sumatra, their serpent-charmers, the Zulus, their rain doctors and *tnwalas*, these are among the examples of the earliest formation of the medical branch in the social segmentation of primitive peoples.

In compliance with the law governing the multiplication of effects, these primary specializations were speedily followed by secondary specializations, traceable among peoples whose progress in civilization enables us to follow the successive phenomena of their evolution. Thus, among the earliest Greeks, who inherited much from antecedent peoples, and who appear in the arena of history with a complex civilization, we find, at the Homeric period, medicine locked up in the noisome cabinet of superstition, zealously guarded by an ignorant priesthood, yet in the days of Hippocrates there were regular surgeons to the armies, there were midwives, or navel cutters, there were oculists, dentists and lithotomists, and there were *iatreia*, or clinics, both public and private. Rome, which began with the *augurs* and *haruspices* and other practicians of base superstition, had so far exemplified the process of specialization, that by the time of the Empire, there were not only general practicians, but there were, according to Baas, "oculists, aurists, surgeons, dentists, uroscopists, specialists in bleeding, catheterization, and clysterization, herb doctors, milk doctors, gynecologists, movement curers, specialists in private diseases, in the treatment of fistulæ, in the cosmetic art, hair doctors, wine doctors, hernia doctors, etc."

We all understand that this high degree of specialization occurred as the distinguishing feature of the highest civilization ever attained before our own epoch. It was the highest degree of social organization known to other than modern history. This was true, not only of the medicine of that period, but of all the avocations of life. The process of segregation had been carried to its logical limit, until each resultant product was without that potentiality essential for its perpetuation. A cycle in the evolution of the race had been defined—a cycle as clear, as distinct, as inevitable as that which marks the moulting of the dove, the flowering of the rose, or the precession of the equinoxes. Majestic forces operating under resistance had sustained deductions at each successive stage, until motion had practically ceased, and humanity, a trivial plaything in the arcana of nature, was brought to a state of relative equilibration. The heterogeneous had resolved itself into the homogeneous, the specialized had become the generalized, and the inactive the inert, as the world, wrapped in the Lethean mantle of the church, dropped into its long, reposeful sleep. From this sleep the giant of humanity finally awoke, refreshed and surcharged with potential force with which to inaugurate another cycle in the evolutional development of our race. Again we see in the great laboratory of what we are pleased to call civilization the same laws producing the same results under the same conditions. Again do we see the homogeneous undergoing division, and the process of specialization again at work. In illustration of this fact, it is to our present purpose only to speak of our own profession since the breaking of that dawn which shed its most effulgent rays in the dark corners of the cloister. At that period, the church, in its complete dominance, had usurped practically all the functions of society. The church was, in fact, the form and expression of the homogeneity of that somber period. As a consequence, when the work of social segregation was again inaugurated, the healing art was exercised exclusively by the priesthood, which had been the custodian of its secrets during the long, dark centuries. The sons of the monasteries were in those days, in the broadest possible sense, "general practitioners," but the natural process of specialization was again soon manifest in this as in other departments of social evolution. In France, for instance, at the end of the Middle Ages, the work of segregation was manifested by the separation of medicine and surgery. The surgeons were, in turn, further segregated into classes, one of which was composed chiefly of barbers. Other specialties, more or less crude in conception, ill-defined in limit, and inefficient in application, were developed in numbers quite as great as those which characterized the "specialisms" of the Roman epoch. The same evolutional changes were manifest in England and Germany, indeed, all of Western Europe was demonstrating the operation of those sociologic laws, the existence and effect of which I have endeavored to emphasize in your presence today.

But it were impossible and quite aside from my purpose to trace the gradual development of our art along the lines which I have indicated. Modern specialism in medicine—a present product of this process of social segregation—may be said to date from the period when the French schools, in the early decades of this century, took up seriously the question of pathologic anatomy. This was the basis upon which the work of division began. The imitative Germans zealously followed the example of their more progressive neighbors of the South, with the result that, today, the great profession north of the Rhine, through the influence of specialism, has attained a dignity and a distinction which it never before enjoyed. In Great Britain the division of work, scientific and practical, was inaugurated at about the same time, although in this regard, as in others, the profession of our mother country has been very conservative The United States, during the earlier decades of national existence, was largely controlled by European influence—at first French, then German, latterly English—while today she is thinking for herself and moving for herself, quite independently of foreign initiative, along lines which make for progress The obstetric art is as old as the function of reproduction, although the latter ages have witnessed its present refinements It has been said "obstetrics married surgery, and that the fruit of the union was bright-eyed gynecology" The accouchement probably occurred at the time Récamier invented the speculum in 1801 Abdominal surgery had its rational beginning in 1809, under the masterly hand of the immortal McDowell of Kentucky, and must stand as America's conspicuous contribution to surgical progress Everything in medicine and surgery from that day to this is essentially contemporaneous history, in which occur conspicuously many of our proudest American names But pardon these references, they are not made to revamp an old story, but rather to give force and illustration to my contention that specialism became a verity in response to natural laws, which even today determine its destiny

We have come to that point in our discourse when we may with propriety ask Has specialization today been carried to that degree that its resultant products stand without the potential force necessary for their further perpetuation? Is our science today in the imminence of a fatal equilibration? To each of these inquiries I answer "no" And I say it, too, in the presence of the fact that never before in the history of human activity, neither in Greece nor in Rome, has specialization reached its present degree of refinement But, happily, the present cycle of civilization is characterized by the operation of forces which found no exemplification in the earlier plays on the great stage of the world Today, responsive to the edict of the gentle Nazarene, neither cloister, halls, factory, shop, college, school, family nor profession, withholds its modicum of knowledge that may make for the common weal The proclamation of love heralded from the Mount, today reverberates through the nations In conformity to natural laws love itself has segregated into emulation, generosity and benevolence Herein is the corrective tendency of the specialism of today It is fully exemplified in the proceedings of this and similar organizations, which meet annually to discuss the accumulated knowledge of the year, and then, not only in the convention hall, but through the avenues of the medical press, to lay the matured products of their wisdom, as a freewill offering, upon the common altar of the profession In this way, knowledge, instead of remaining in the hands of those who evolve it, becomes disseminated for the common welfare There is not a day but that the general medical profession becomes enriched in resource and potentiality by the accretions derived from specialism It would seem that in this way one specialty after another must sooner or later lose its distinctive characteristics and return to the great body of the profession from which it was derived What with our colleges, universities, clinics, hospitals, journals and societies, the connection between the specialties and the general profession is always close and intimate The characteristic of the present era, one that distinguishes it from former civilizations, is that the process of specialization is never carried to the point of complete segmentation Each specialty, however assiduously cultivated remains an integral part of the great general profession, the masters of which must ever stand as our ideals All specialists today are primarily the products of general medical culture The act of specialization takes place after and not before entrance into the general profession When this order is changed, then comes the day of danger Unlike the specialists of Greece and Rome, those of today are physicians and something more, and happily, their influence is to make something more of physicians This tendency, which in Germany has come to its fullest fruition, is already marked the world over, But a few decades ago, the practice of gynecology, as now known and understood, was in the hands of a few practicians, to whom it brought compensation and distinction, today it is in the hands of the multitudes, to whom it brings neither It may be said that the general knowledge of gynecology has gone back to the profession where it belongs Those who remain practitioners of that department maintain their position by the joint influence of voluntary self-assertion and special adaptability It is undeniable, however, that with reference to our own department of practice the lines are shifting From the pelvis to the abdomen was but a natural step in the application of our surgical resource Those who were gynecologists but a few years ago are, many of them, abdominal surgeons today, with an unmistakeable tendency to become general surgeons tomorrow

While all this is true, there remains a *raison d'être* for organizations such as this devoted to the cultivation of special departments of knowledge, and there will continue to remain a reason for the continuance of specialists in each of the recognized departments of medical science and medical practice This reason is to be found, first, in the highest interests of the general medical profession, and next, in the highest interests of the masses, who are its beneficiaries From the standpoint of the medical profession, each specialty, as has already been stated, is to be recognized as an integral and organic part, a distinct member controlled by its distinct center in the general sensorium, but a center in thorough correlation with its associated centers With this idea the development of a specialty is nothing more nor less than the development of a particular part with a particular function—a development which tends in the direction of increasing general efficiency No matter how generally diffused may become the knowledge of, for instance, gynecology, there will yet remain within the domain of those subjects which are capable of still further development attractive incentive for work The cultivation of these departments must remain in the hands of those who honestly concentrate themselves upon the task To such devotees as honestly assume this attitude and its attendant responsibilities, will always be accorded recognition and reward - But the condition which can perpetuate specialism, in this or any other department, is a narrowing rather than a broadening of limits The broadening of limits tends to ultimate mergence and to homegeneity A large number, possibly a majority, now identified with special work, may elect to shift their personal activities in this direction, while there are others who, standing upon an equally strong basis of general culture, will decide to concentrate their energies in carrying to further refinement and perfection a more limited department of science. Thus, happily for the progress of the world, specialism will not disappear from society. On the contrary, specialism is manifestly to be even more distinct than in the past, while specialists, as known to the broad and progressive profession of America, will be able to gain recognition only by conforming to severer tests than are now applied. It is safe to predict, therefore, that in the not distant future there will be fewer specialists, but, happily, better ones. The lines may, and possibly will shift. Existing specialties, or certain of them at least, through the influence of further segregation and final equilibration, may, and probably will, disappear into the general profession, while segmentation will be inaugurated at other points to result in the development of other specialties. Thus shall the great future witness the mutations of progress.

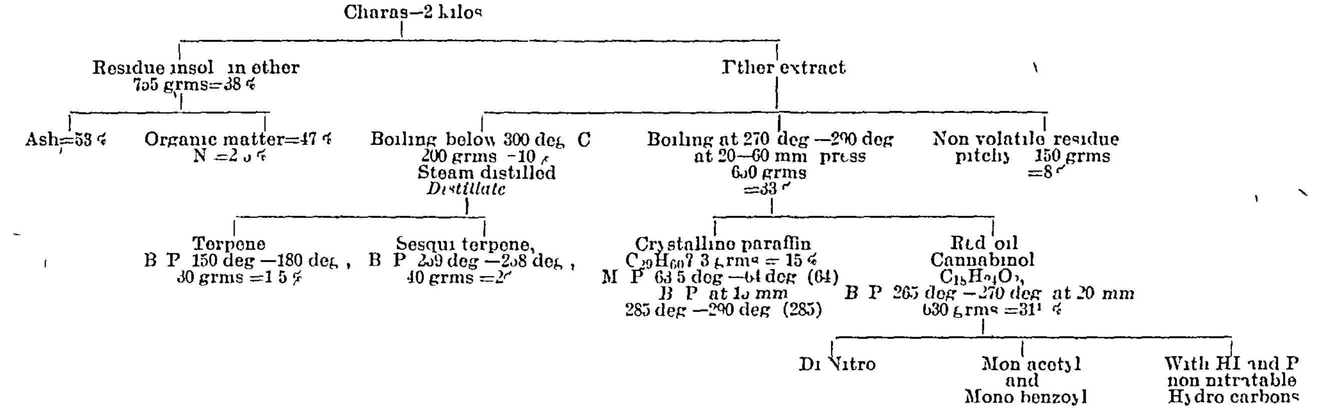
A CONTRIBUTION TO THE PHARMACOLOGY OF CANNABIS INDICA

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY C. R. MARSHALL, M.D.
ASSISTANT TO THE DOWNING PROFESSOR OF MEDICINE, CAMBRIDGE

Notwithstanding the large amount of labor which has been expended on Indian hemp, we know comparatively little of its pharmacology. The active principle, it is true, has been isolated, in a more or less impure form, by O'Shaughnessy, Robertson, the brothers Smith, and more recent investigators, but the more important question of the changes this undergoes has not, as far as I am aware, until recently, been attempted. To me this is the most interesting part of the inquiry. Apart from the great financial loss entailed by the growing inertness with age of the drug, the variability in the strength, its preparation has led to numerous misfortunes in medical practice, and a distrust in its use as a therapeutic agent. The isolation of the active principle of the drug would not matter if we could only insure our preparations being of constant strength. But, without knowing the cause of the increasing inertness, this it is impossible to do. With this cause, among other questions, I intend to deal in this paper.

As I have dealt elsewhere[1] with the history of the active principles of Indian hemp, I shall confine myself in this communication to the work of the most recent observers. Two and a half years ago three Cambridge chemists—Wood, Spivey and Easterfield—commenced a re-investigation of the chemistry of Indian hemp. They worked with charas, as being the most active preparation of the plant, and by extraction with organic solvents (alcohol, ether, petroleum ether, etc.) and subsequent fractional distillation, they isolated a mono- and sesqui-terpene, a crystalline paraffin and a resinous body (cannabinol), an indistillable pitch and an insoluble sandy residue were left behind.[2] The proportions of these substances are shown in the subjoined table, taken from a communication by Easterfield and Wood to the Cambridge Philosophical Society.[3]



Other samples more recently examined have not been found to be so good as this. A second lot contained only 15 per cent. cannabinol, and a third only 10 per cent. Furthermore, the cannabinol from these samples was not so pure as that obtained from the first sample and from the cannabinol obtained from the last the acetyl derivative of a higher homologue of the pure substance has been prepared. This homologue was present to the amount of 10 20 per cent.

The products (with the exception of the paraffin) and certain impure intermediate substances were passed on to me for pharmacologic examination. I naturally turned my attention first to the resin. The terpenes were present in too small an amount, and their chemic constitution and physical character were not such as to suggest a cannabis-like action. Personne,[4] it is true, attributed the activity of the drug to an oily liquid, *cannabene* ($C_{18}H_{20}$), which Valenti,[5] and more recently Vignola,[6] have shown to be an impure sesqui-terpene, but Roux[7] has proved physiologically that cannabene is not the active principle. On the other hand, numerous investigators had shown that the active principle is of a resinous nature. The paraffin was only present in very small amounts, and from its constitution and properties it is easy to infer that it possesses no marked physiologic properties.

The resin was found to be active. It possessed, as far as I could see, all the peculiar effects of the hemp plant. The question to be settled was its purity. As it boils at 265 to 270 degrees C, under 20 m.m. Hg pressure, and possesses a constant composition, the presence of an impurity seemed improbable At least it could only be due to a stereo chemical isomer or a substance with closely allied composition and properties The possible presence of an alkaloid was avoided by treating the crude drug with dilute sulphuric acid before commencing the investigation But no alkaloid has been found in charas

In a more or less impure form cannabinol has been isolated from various commercial preparations, viz Merck's cannabinon, extractum cannabis Indicæ ethereum, resina cannabis Indicæ, and T & H Smith's cannabin

PHYSIOLOGIC INVESTIGATIONS

Experiments have been carried out on cats, dogs, rabbits and myself, and the investigations have been mainly confined to the administration of the various substances by the mouth—a condition necessitated by the comparative insolubility of the drugs With the experiments in detail I do not intend to deal—admirable descriptions have been given by various observers, both in this and other countries—but in appendix I will be found types of experiments and in appendix II a synopsis of the experiments made By combining these and referring to the text, little difficulty will be experienced in forming mental pictures of the condition in each individual experiment

Most of my experiments were made upon two dogs One was a mongrel puppy something like an Airedale terrier in breed, the other was a young adult fox terrier Later a third dog, an English terrier, was added The first two dogs were of very different temperament, the one (Airedale terrier) was self-reliant and intelligent, the other was affectionate, but nervous to an extreme degree The English terrier although timid, possessed much more character than the last one This question of temperament, I believe, is of considerable importance in dealing with the finer effects of cannabis indica The cats were adults, the rabbits young, usually 3 to 4 months old

The *terpenes* in the comparatively small doses in which I was able to give them, produced no noteworthy symptoms beyond slight diuresis In rabbits there seemed to be slight transient excitement, but the compound given to these animals was impure On myself 0 5 c c produced no effect, 2 c c (sesquiterpene) slight and transient listlessness and heaviness of the head

The *resin*, cannabinol, in dogs constantly produced the same qualitative effect, although it varied slightly in the different animals and in the same animal from time to time The first noticeable symptom (one half to two hours) was slight lassitude and an appearance of heaviness about the eyes Gradually the depression increased and sleepiness and usually sleep followed, yawning and sighing were not infrequent the body when standing swayed from side to side and this gradually increased until the animal fell over or suddenly pulled himself up with an effort Usually after falling he remained in this position and went to sleep Sometimes the rocking motion occurred in an antero-posterior direction, especially in the fox-terrier In this animal, too, the standing position was more characteristic, the hind legs being half bent In this position and markedly unsteady he usually stood gazing into the fire Distinct ataxia during walking was present or absent according to the dose After large doses the attention was blunted, but after small ones no effect in this direction was noticed After three to six hours the animals began to improve At this period the larger sometimes became extremely frolicsome and if played with would run about barking in a high-pitched voice Usually both animals slept or lay before the fire until taken to the kennel for the night

When under the influence of the drug, the pupils were sometimes slightly dilated, sometimes unaffected occasionally contracted, the pulse and respiration were slowed, but whether more than could be accounted for by the condition of rest it was often difficult to decide My general impression is that the pulse was slower than during ordinary sleep The temperature, with one exception, invariably fell, at the most not more than 3 degrees C, usually not more than 1 to 2 degrees C The fall naturally varied with the temperature of the room It was most marked in the fox-terrier, and in this dog trembling was not an infrequent symptom The reflexes were always present and the sense of pain was doubtfully blunted, the olfactory sense, however, seemed depressed Vomiting was a frequent symptom, salivation, independent of any emesis, a rare one In the fox-terrier, increased micturition was occasionally obtained The influence of dose was not marked Generally speaking, the symptoms were fairly constant, but owing to the insolubility of the material complete absorption was difficult to insure Consequently, in dogs at least, a strictly quantitative comparison could not be made Occasionally a small dose produced more marked symptoms than a larger one, but this was rare, and in the fox-terrier the onset of the symptoms as a rule was later and they lasted longer than in the other dogs On the whole, however, the symptoms were fairly proportioned to the amount given After small doses (0 02 g per kg) quietude, heaviness about the eyes, sleepiness and usually slight unsteadiness occurred, attention was not appreciably affected, and the symptoms almost passed away in five or six hours In the English terrier this dose produced a very marked effect, the ataxia being as severe as after much larger doses to other dogs After large doses (0 1 g per kg) there were marked depression, ataxia, vomiting and sleepiness, although sleep was not an invariable symptom In the evening food was refused, but the following morning they seemed quite well

In cats effects similar to those occurring in dogs were obtained, but the action was more severe and prolonged After a dose of 0 058 g per kg improvement did not commence until after twenty-five hours The depression and muscular weakness were more marked than in dogs, and salivation was a more constant symptom Total anorexia and consequent loss of weight occurred after large doses A detailed description of an experiment will be found in appendix I

On rabbits preparations of cannabis indica exert comparatively little effect This was observed by O Shaughnessy, and it has been noted by more recent investigators The same effect was obtained in my own experiments with cannabinol But I am inclined to believe that the immunity is more apparent than real After large doses, slight depression and quietude are the only observable symptoms but on further examination a fall in the number of heart-beats and respiration and the temperature was found to occur, the animal refuses to eat and death usually ensues The low cerebral development of these animals prevents them showing unmistakable signs of cannabis poisoning, and these are only found in observations on the vegetative functions The lethal dose, however, is much larger than for dogs or cats

The effect on myself was very similar to that described by other observers as peculiar to Indian hemp After large doses (0·1 g) there was a sensation of dryness of the lips, and of increased viscidity of the buccal mucus, a pleasurable tingling throughout the body, muscular weakness, slight ataxia, risibility and loss of time sensation My pulse was said to be increased in frequency, sensation was somewhat blunted, and the pupils were slightly dilated

After small doses (about 0 02 g) the first symptom was usually loss of power for mental work A typic condition of mental exhaustion set in Sentences could not be conceived, except by powerful efforts, and these were not often forthcoming

After intermediate doses (0 05 g) the ability to work was lost altogether I usually sat before the fire doing nothing, almost thinking of nothing There was a marked unwillingness to move Pleasurable tingling in the limbs, very slight ataxia and other symptoms similar to those obtained after a larger dose were present Time passed quickly Sleepiness was sometimes, but not always, present As an early symptom a peculiar indistinctness of the periphery of the visual field occurred, and later it was found that the point of regard was made to travel with greater difficulty, as along the line of a page Depression usually continued throughout the following day

The residual *pitch*, when dissolved in oil, was active, but much less so than cannabinol The symptoms were the same Given in the solid form it exerted little effect In all probability the activity was due to unchanged cannabinol present Certain intermediate impure products were tried, but none of these was as active as cannabinol The insoluble residue was inactive

THE ACTIVE PRINCIPLE

Thus, by a process of elimination, cannabinol was found to be the most active ingredient of the charas products But in order to determine its comparative activity, control experiments were made with the crude material and extracts obtained from it The natural product exerted much the same action as cannabinol, but both spirituous and oily extracts were somewhat more active, a similar result was obtained with Merck's cannabinon This raised the question as to whether cannabinol is the sole active ingredient of the plant I think we must assume that it is, at least, the active principle The symptoms produced by the natural product and the resin are practically the same, and this is an important point It suggests that we must look for changes occurring in the resin either during its manufacture or subsequently, or to a diminished absorbability as compared with extracts of the crude product That faulty manufacture, etc , will produce a more or less inert substance, will be seen from evidence given later, but I am inclined to attribute to the lessened absorption the more important rôle The terpenes probably increase the rapidity of absorption of crude extracts, but this I have not yet been able to put to the test That cannabinol does not possess all the activity of the hemp plant I am prepared to admit, but this is the case with most other crude drugs and their so called active principles In the case of charas the terpenes probably aid in its physiologic action, as the crude drug seemed to produce more excitement than pure cannabinol, and when the drug is smoked it is possible that pyrodene and other bases, which are produced by the destructive distillation of the substance, may aid in its intoxicating effects If any other substance aids in its action we have at present no indication of it Moreover, that cannabinol is the chief active ingredient is supported by the fact that the activity of different products is roughly proportionate to the amount of cannabinol they contain, and that the growing inertness of Indian hemp can be explained by changes occurring in this resin

The question of the purity of cannabinol can only be settled by further research, and this, I may add, is being undertaken The only demonstration of its purity in the present state of our knowledge, viz the reconversion of the crystalline acetylized derivative into cannabinol, failed The acetyl derivative was not crystalline and the reconverted cannabinol was much less active, physiologically, than the parent substance This might be explained in many ways, but at present it is idle to speculate

The last and worst sample of charas yielded a substance which contained a higher homologue of pure cannabinol This homologue regenerated from its acetyl compound was physiologically inactive Whether it is active previous to acetylizing is at present impossible to say

THE CAUSE OF THE INACTIVITY OF INDIAN HEMP

The different samples of the same preparation of Indian hemp possess varying physiologic effects, and that good samples darken and deteriorate in keeping has long been known, but until recently no satisfactory explanation of this has been offered In 1894 Leib Lapin,[8] by means of fractional precipitation prepared a substance which he termed *cannabindon* This presented the appearance of "a beautiful dark cherry-red mass of thick consistency, which took the form of the vessel in which it stood, and showed a smooth horizontal surface " Its formula he gives as $C_8H_1 O$ It possessed distinct reducing properties, and rubbed up with chocolate and left a week, its physiologic action was in great part lost The latter he explains as being due to an oxidation of the preparation resulting from its finely divided state and its contact with fat and air, and he strengthens his position by a reference to the similar behavior of ergot, which undergoes oxidation less readily than cannabindon. The oxidation product he states "is inactive or very slightly active "

Although I was aware of Leib Lapin's views, my own researches were carried out independently What first drew my attention to the matter was the gradual darkening which cannabinol underwent when left exposed to the air in a test-tube the darkening commenced on the surface and gradually extended downward, the superficial layers being affected rapidly, the deeper layers very slowly In order to determine whether this was due to oxidation, and whether in consequence the activity was affected, oxygen was slowly passed through cannabinol kept fluid by immersion in a sulphuric acid bath at 150 to 160 degrees C The material rapidly darkened and the consistency increased After passing the oxygen through for six hours the activity was found to be decidedly less It was then bubbled through for thirteen hours more, the temperature toward the end of the experiment being raised to 185 degrees C in order to keep the substance fluid On cooling, the substance set to a hard, brittle mass, exactly resembling pitch in appearance. No loss or gain of weight, within the limits of experimental error occurred. This pitchy material given in the solid form possessed scarcely any action, but this in part is due to the lessened solubility and higher melting-point, for if previously discolored in oil, a distinct, though comparatively slight, effect is obtained. Dr. Easterfield, who has made all the analyses in connection with the charas research kindly undertook one of the oxidized cannabinol. The percentages obtained, compared with those of cannabinol, were

---

[8] Ein Beitrage zur Kenntniss der Cannabis Indica Diss Jurjero, 1894.

Calculated for $C_{18}H_{24}O$ (cannabinol)	Found	Calculated for $C_{18}H_{24}O_3$
C=79.4	C=77.7	C=75.0
H= 8.8	H= 7.5	H= 8.3

The product obtained was therefore not completely oxidized, and the activity it retained was in all probability due to unchanged cannabinol. As a control experiment carbon dioxid was passed through a similar sample of cannabinol similarly treated. Very slight darkening, probably owing to slight admixture with air occurred, but there was no increase in consistency. Only a slight diminution in activity was observed.

The influence of temperature was tried. Cannabinol distilled at 400 degrees C. under atmospheric pressure was found to be slightly less active than cannabinol distilled at 265 degrees C. under 20 mm. Hg pressure, but when the substance was heated in sealed tubes at 220 to 260 degrees C. for twenty-four hours, no very great loss of activity occurred, although this was distinct. As slight oxidation may have resulted during the process, the influence of temperature *per se* may be disregarded. The action of aqueous vapor has not been determined.

It would therefore seem as if the loss of activity of Indian hemp was due to oxidation of the active ingredient. The terpenes, like other members of this class, readily hydrolize, and this, doubtless exerts some effect in the deterioration of the crude drug. The obvious remedy is to keep cannabis preparations in air tight vessels until they can be used. For practical purposes a well-corked bottle seems to be sufficiently protective, but hermetically sealed packages, especially for transport purposes, are to be prepared. In sealed tubes we have kept cannabinol for seventeen months without the slightest change.

The limitation of the oxidation to the superficial layers probably explains many of the accidents occurring in practice. If the preparation has been long in stock and imperfectly protected, these may have become comparatively inert, and scarcely any effect may be produced, while a renewal of the prescription from deeper parts—or the substitution of a more recent preparation—may produce very marked effects. I am certain that the accidental administration of superficial and deep layers of cannabinol will explain some discrepancies in my own results, which previously were inexplicable.

As regards a chemical test for the physiologic activity of cannabis compounds, none exists, and the only indication at present is in the direction of their reducing power. This will probably give us some information, and I hope to deal with the question later. As far as cannabinol is concerned, the transparency is the best ready indication of its purity. When placed in an ordinary test-tube print ought to be read through it with ease; any blackening is due to admixture with oxidized material. If not carefully prepared impure products are readily obtained, and such give no more constant results than the ordinary preparations on the market. The transparency, however, is not an absolute indication of its purity, for the higher homologue of cannabinol, which, when derived from its acetyl compound is inactive, is almost as transparent as cannabinol itself. What the physiologic effect of this compound is in the natural state, it has not been possible to determine.

SUSCEPTIBILITY.

But the variation in activity of the preparations of Indian hemp will not account for all the differences in effect produced. A difference in individual susceptibility also exists. What this is due to we do not know. It is probable that certain types of men are more susceptible than others, and that certain habits, such as the alcoholic, have an inhibiting influence in this direction. The subject is a difficult one to treat from a purely experimental point of view. In the dogs the greatest effect seemed to be connected with greatest mental stability, but how much of this was due to variability of absorption and how much to individual differences it is difficult to say.

The following case which recently came under my notice is of interest in this connection, as it enabled me to compare the effect of the same dose on myself. A gentleman suffering from neuralgia took ¼ grain extractum cannabis indicæ (B. P.) in the form of a pill. The pills were made up by a well-known London druggist. The following account was written by the patient himself. "At about 4.30 on Sunday, feeling neuralgic pain in the right eye, I took one of the pills. I then had tea and read aloud for some time, feeling nothing unusual. But about 7.30, when dressing for dinner, I began to suffer from very curious feelings. I felt giddy and seemed to lose command of my actions, thoughts seemed to pass rapidly through my brain and I hardly felt responsible for myself. I went to my wife's room and described my feelings. She was alarmed at my appearance and said I was very white. I felt a sort of burning uncomfortable feeling inside and I tried to make myself vomit by drinking several tumblerfuls of hot mustard and water. This was partially successful, but I felt very ill and a doctor was called in. When he came I was unable to speak coherently, sentences were disjointed, and my memory partially failed me. I was ordered to bed and undressed with difficulty. I then shook violently all over, and my hands were cold and tended to contract. I was given some brandy and water and gradually I became more natural. Afterward I took some soup and fish. During my sleep I felt inclined to laugh, but I do not think I actually did so. The next morning I was comparatively well, but throughout this day and the next I did not feel quite well; there was a numbness and coldness in my legs and I feared I was in for an attack of influenza, but my temperature was normal." The neuralgia was cured, but afterward he told me he would rather bear the pain than the effects of the remedy. The remainder of the pills were given to me and on two occasions I tried them on myself. On both occasions the usual effects of Indian hemp were produced, viz., paresthesia in the extremities, inability to do mental work and sleepiness, but not the giddiness and other symptoms produced in the case cited. The effect may in part be due [illegible] and the absence of fear in consequence, but this is insufficient to account for all the difference The prescription was dispensed by a first-class pharmacist and there was no reason to believe that the extract was unequally shared

THE ABSORPTION OF CANNABINOL

For all practical purposes, cannabis preparations may be regarded as being quite insoluble in water, They are soluble in fats and organic solvents generally, but with the exception of fats these are not common constituents of the contents of the alimentary canal It is even doubtful what part fats play in the absorption of the drug If Moore and Rockwood's[9] view of fat absorption be accepted, the only influence they could have would be a physical one—the substance would be brought into a state of finer division and thereby rendered more susceptible to other agencies When given dissolved in oil, the onset of the symptoms is not distinctly earlier than in other cases, but as absorption probably only occurs from the intestine this observation is of little consequence The more important question is the solubility of the active principle in dilute acids and alkalies respectively According to Kionka[10] the resin of Indian hemp is insoluble in alkalies From the therapeutic point of view Germain Sée[11] states that cannabis is the peculiar sedative of the stomach Both these statements suggest that the active principle is soluble in an acid medium, and this is supported by the fact that cannabinol is actually soluble in strong sulphuric acid and glacial acetic acid But my results for dilute acids are opposed to this view, and contrary to the statement of Kionka, I find it soluble in dilute alkalies The following experiment proves this Two Erlenmeyer's flasks were taken, into one (A) was put 2 127 grammes cannabinol, into the other (B) put 2 335 grammes Both were left over sulphuric acid until they attained a constant weight, 100 c c, 1 per cent caustic soda solution was then added to A and 100 c c, 1 per cent hydrochloric acid (gas) to B Both were shaken occasionally and left twenty-four hours The alkaline solution soon became of a purplish color, which deepened, the acid solution remained perfectly clear After standing twenty-four hours, both solutions were poured off and the remaining cannabinol was rapidly washed with distilled water until the washings were free from acid and alkali respectively The flasks were again put over sulphuric acid and left until the weight became constant The alkali containing flask (A) had lost 0 03 gramme cannabinol, the acid containing flask (B) 0 005 gramme, the latter being within experimental error

It is therefore probable that the cannabis resin is absorbed under the influence of the alkaline juices of the upper part of the intestine In the mouth, solution occurs to a slight extent, as is evidenced by the peculiar unpleasant taste, but this can not be of practical importance The influence of other alimentary conditions has not been determined

The condition of the stomach, however, plays an important part in the time of appearance of the symptoms, probably by hastening or retarding the course of the drug to the intestines Thus in one case, when the drug was taken on an almost empty stomach, four hours passed before the onset of the symptoms, whereas if taken just before a meal, the first symptoms invariably occurred within one and a half hours Taken after meals the appearance of the first symptoms is variable In atony and dilatation of the stomach cannabis is said to be inactive (as a gastric sedative) The small solubility of the drug, even in alkalies, probably accounts for the insidious onset of the symptoms and its prolonged effect

HABITUATION

In order to determine roughly the influence of continued dosage on the activity of cannabinol, the two dogs were given very large doses every day for a week A small dose, similar to one given just before the experiment, was then administered and its effects watched The influence was certainly less than on the previous occasion, but the diminution was not marked Whether habituation to this remedy occurs less readily than with other hypnotics can only be determined by practical experience, I know of no reliable observations on the subject, although it must be well known In any case the tolerance is not likely to be so great as in the case of opium

During my experiments with the two dogs, this question of tolerance often presented itself, and it was on this account that a third dog was obtained Of the greater susceptibility of this there could be no doubt, but to a certain extent it was only apparent The experience was new to him, he walked about and stumbled when the other dogs would have laid down The same thing happened in the earlier experiments with these dogs, the ataxia was marked, later, they learned wisdom by experience, and laid down soon after the drug was given It was often difficult to get them to stand sufficiently long for any indications to develop

Although my experiments did not show any great amount of tolerance, they seemed to me to show some mental depression, the normal physical life of the animals seemed to run on a lower level, although this was difficult of proof That cannabis indica exerts a powerful depressing influence, on some individuals at least, there can be no doubt, and from experiments on myself I have little hesitation in joining the ranks of those clinicists who regard Indian hemp as a causal factor of insanity But this point, and others, I hope to develop in a later communication

EFFECTS ON SPECIAL ORGANS

Owing to the insolubility of cannabis preparations and the pressure of other work, exact experiments on the different organs have not been carried out A solution of cannabinol was made by heating an excess of the substance in a 1 per cent solution of sodium bicarbonate on a water bath, but the resulting product, which was of a brownish color and probably contained about 1 in 1000 cannabinol, had no distinct influence on blood-pressure A solution of cannabinol phosphate (8 per cent) in one experiment caused a slight fall and subsequent rise of blood-pressure, but from other points of view this substance was but slightly active

Cannabinol is, however, somewhat depressant to the heart A fall in the number of beats was constant, and in many cases this seemed greater than could be accounted for by the rest and sleep Thus, in the largest dog, a pulse of 108 fell to one of 48, and a slight irregularity, also noticed in rabbits, occasionally occurred That the blood-vessels were not dilated was inferred from a comparison with the action of chloral After this drug, there was not the same marked fall in the number of the heart beats, and the character of the beat was slightly different After a large dose of cannabinol my own pulse increased in frequency, after a small dose no effect was noticed, after intermediate doses I invariably forgot to take it No distinct effect on the respiration was observed It was slower and deeper, as in ordinary sleep

[9] Journal of Physiology Vol xxi p 58

[10] Liebereich's Encyclopedia der Therapie Erst Bd s 556

[11] Ibid s 557

In the fox-terrier increased micturition was not infrequent, but this was not observed in the other dogs Constipation was not an obvious symptom After continued dosage some evidence of it existed, but this was not seen after single doses In myself it was rarely present Salivation was an occasional symptom, but as this occurs in dogs and cats after the exhibition of drugs possessing no specific properties in this direction, it is not probable that cannabinol exerts any specific action in this way In my own case dryness of the mouth was a more constant feature

The main action of cannabinol, however, is on the nervous system, and probably on the cerebral cells From introspective analysis it is difficult to avoid the conclusion that some peripheral action exists, but as all the symptoms can be explained by a central influence, it is simpler, in absence of proof, to accept this

One of the most prominent physical symptoms is the loss of time sensation This is mentioned by most writers But it is not peculiar to Indian hemp, as it occurs after mescal button and other drugs of a similar nature Its explanation, to my mind, is simple The estimation of time is a complex act and dependent upon our calling to consciousness a series of events When the physical state is depressed by Indian hemp a succession of ideas cannot be maintained, time ceases to exist, and it can not therefore be estimated Even the apparently slowly travelling second hands of a watch, which is observed when under the influence of Indian hemp, may be explained in a similar way The power of conception is more or less lost, current events are rapidly forgotten while those fixed in the memory by older associations may still be recalled Under the full influence of the drug, even those too are forgotten, and one's whole previous existence seems to be blotted out

A most interesting condition, after large doses is the occurrence, alternately, of loss of control and lucid intervals During the latter, all the elements of complete sanity are present, but the physical state is below the normal level In it the processes on which consciousness depends are readily exhausted, and the condition of irresponsibleness develops Slight mental strain during the lucid periods seems to hasten the occurrence of a state of irresponsibility A more complete rest from thought brings back the rational intervals The over estimation of distance was never distinctly observed by me, except to a slight degree on one occasion The effect is probably connected with the increased effort made to accommodate the ocular muscles to the required distance and is dependent on deficient will power Hallucinations, too, of a very slight character were only present in one instance—a result probably attributable to my lack of imagination In dogs, after large doses, the attention was blunted, and they became less obedient As far as I can see there seems to be no selective influence on any psychical phenomenon All such processes are depressed, but whether to an equal degree I am not prepared to state With this question however, I hope to deal at some future time

ILL EFFECTS

The most common ill effect, or rather after effect, I have experienced, has been depression, lasting the whole or greater part of the following day, after a large dose (0 1g) This, and the accompanying mental exhaustion, were decidedly painful, and the effect was markedly prolonged by attempts to do an ordinary day's work

In dogs, vomiting was not an uncommon symptom but this was much less marked than with morphin A slight, occasional irregularity of the heart in these animals and rabbits, has been mentioned, and a similar condition, viz an increase in the cardiac irregularity of heart disease has been observed by Prior[1] after cannabis preparations, in men

DERIVATIVES OF CANNABINOL

These have been investigated in connection with experiments on the constitution of this body Oxy-cannabin ($C_{11}H_{11}NO_4$) is inactive, at least in moderate doses Acetyl-cannabinol and the cannabinol regenerated from it were but slightly active The acetyl compound of the higher homologue of cannabinol, as as well as the substance (regenerated from the acetyl compound) itself, was inactive

Tri-brom-cannabinol, a brownish powder, was found to possess hypnotic properties In dogs the action was very slight, but on myself (after 0 1g) sleep and depression were marked, and three days of mental exhaustion followed

Attempts were made to obtain a more soluble preparation of cannabinol, and this was best accomplished by making a phosphoric ester Cannabinol was heated to 100 degrees C with phosphoric anhydride The melt was boiled out with alkalies, which dissolved nearly the whole of it, and this was then neutralized by hydrochloric acid An amorphous substance was obtained, which, on analysis, gave results agreeing with the supposition that it was cannabinol phosphate Physiologically, however, the substance was not very active, and injected subcutaneously into a dog produced an abscess

THERAPEUTIC INDICATIONS

Therapeutically, cannabinol is likely to be a valuable hypnotic It is purer and more reliable than the cannabis preparations on the market, but it does not appear to possess any other advantages over them It is not a powerful cerebral depressant (except in relation to its dose), and belongs rather to the substances termed "sleep producers" than "sleep forcers' Owing to its comparative insolubility its action is prolonged, and this in my own case leads to depression Its advantages are, that its lethal dose is considerable it does not inhibit secretory activity and it does not readily induce habituation Its disadvantages are, the excitement produced by early doses and the depression which follows its use It appears to be a slight analgesic, but how far its activity goes in this direction it is impossible, in the absence of experiments in which pain is present, to say This can only be proved by clinical observation Purely pharmacologic investigations do not support any other actions of this drug, but so far as they have been carried they do not deny their existence

In conclusion, I express my thanks to Messrs Wood, Spivey and Easterfield, for the material supplied me and especially to [illegible] aste [illegible] for the hel[illegible] he has given me during [illegible] work

Appendix I

TYPES OF EXPERIMENTS

Descriptions of personal experiments will be found in the *Lancet* P=heart beat, R=respiration, T=rectal temperature

Dog (English terrier), wt 7180 grams, P, 102, R, 16, T, 38 2 degrees C, (room temperature 20 to 22 degrees C), 12 10 o'clock, 0 14 gram cannabinol, 12 40, slight depression, distinct unsteadiness, 12 45, ataxia more marked, head unsteady, eyes heavy, 12 55, very unsteady, will not lie down, pricked up ears when cart passed window, no dilatation of pupils, 1 10, extremely unsteady, continually falling over, will not touch milk, P 96, T 37 7 C, 1 40, ataxia rather worse, still walking about, 1 50, vomited small quantity, mainly yellowish fluid, 1 54, vomited again, 2 10, condition same, constantly falling over, P 108, T 38 6 C, 2 20, vomited again, 2 30, *circus movements, then sat down, got up* and repeated several times, 2 40, vomited, 2 50, vomited, 3 10, slightly better, but still falling over, P 108, T 38 9 C, 3 40, been laid down last twenty minutes, slept partly, just got up, ataxia very much better at first but soon developed again, 4 10, sleepy, P 96, T 38 5 C, 4 40, still marked ataxia but much better, 5 15, further improvement, still unsteady and depressed, P 96, T 38 9 C, following morning, apparently well This was the only case in which a rise of temperature was noted

Dog (Airedale puppy), wt 6500 grams 10 30 o'clock, 0 5 gram cannabinol given in bread, P 192, 11 30, lively, no obvious effect, 11 45, sleepy, lay down, 12 30, still in same position, yawning, came when called but seems rather stupid, 1 00, walking about, when played with commenced to run about and bark in a higher pitched voice, 2 00, been asleep for last half hour, does not answer to name so readily, weak on legs, can not stand steadily, 3 00, condition same, asleep, P 96, 4 00, still asleep, occasionally wakens up, yawns and stretches, will not answer to name, 5 30, condition much the same, still weak on legs and tired, sent to kennel, would not eat, following morning, apparently normal

Cat, wt 3600 grams 1 30 o'clock, 0 15 gram cannabinol given in meat, 2 30, no apparent effect, 3 00, sleeping, 3 45, awakened, rather weak on legs, gait slightly unsteady, 5 00, much worse, distinct inco ordinate gait but does not move about much, has been laid down mostly, with chin on ground, passed a loose motion, would not drink milk although seemed eager for it and only ate two small pieces of meat

Second day, 9 30 oclock, no apparent alteration, still stupid would not come when called, distinct muscular weakness, gait still unsteady pupils somewhat dilated, would not drink milk although a little had been drunk during the night, 2 30, slightly better, gait less unsteady, 5 30, still better, looks up when called, ataxia still present, following morning, seemed quite normal

Rabbit, wt 620 grams, P, 300, R, 76, T, 38 4 C

First day, 2 25 o'clock, 2 4 grams cannabinol given in mucilage, 5 25, has been quiet since drug was given, eyelids partially closed, slightly depressed, doubtful muscular weakness, P 216, R 30, T 34 1 C

Second day, 10 00 o'clock, somewhat worse, head trembles *slightly*, sensation *blunted but kicks on being handled*, has not eaten any food, P 204, R 54, T 31 4 C, placed before fire, 5 45, seems slightly better, P 150, R 30, T 32 7 C

Third day, 12 15 o'clock, condition much the same, trembling of head present, eyes half closed, P 168, R 60, T 29 1 C, 5 30, slightly increased muscular weakness, pupils more dilated, been laid before the fire all day P 204, R 36, T 31 8 C

Fourth day, 11 00 o'clock, no noticeable change, P 138, R 39, T 30 6 C, 6 00, much worse, trembling very marked

Fifth day, 9 00 o'clock, found dead, rigor mortis, cold, afternoon, few small petechia in stomach, otherwise normal, stomach and cecum full of food

Appendix II

This appendix contains a summary of the experiments made on which the foregoing account is based Only the briefest description is given, but some attempt has been made to indicate the comparative value of the experiments The experiments are given in the order they were made The time in parentheses indicates the period after administration of the drug at which the preceding symptom was noted, m, minute, h, hour

EXPERIMENTS ON DOGS

Three dogs were used, at first only two All were fed at 9 o'clock A M Unless otherwise indicated the individual substances were given in gelatine capsules by the mouth

1 May 5, 1897, Airedale terrier, weight 3100 gms, 0 4 g cannabinol *phosphate, slight depression* and sleepiness

2 June 4, 1897, Airedale terrier, 4400 gms, 0 4 g cannabinol phosphate hypodermically, slight depression and sleepiness, fall in pulse rate, longer effect than in last case

3 June 16, 1897, Airdale terrier, 5400 gms, 1 1 g acetyl-cannabinol, sleepiness and depression (30 m), unsteadiness, occasional slight excitement, vomiting (3 h), dilatation of pupils Quite well next morning

4 July 1, 1897, Airedale terrier, 0 5 g cannabinol, slight sleepiness (75 m), stupidity, muscular weakness and unsteadiness, slept most of day, normal next morning, effect more marked than 3

5 July 15, 1897, Airedale terrier, 7520 gms, 1 g charas, tired, yawning (30 m), sleepy, ataxia, etc, pupils somewhat dilated, very much excited (6 h), seemed normal next day, effect somewhat greater than 4

6 July 22, 1897, Airedale terrier, 0 3 c c ⅙ alcoholic extract charas, depression (60 m), temporary excitement (100 m), weakness and unsteadiness (most marked 5 to 6 h), shivering, involuntary micturition, slightly excited next morning, very marked effect

7 July 28, 1897, Airedale terrier, 1 c c ⅙ alcoholic extract charas, lay down (75 m), but excited if played with, sleepiness, unsteadiness, etc, as in 6, but symptoms less severe, normal next morning

8 July 30, 1897, Airedale terrier, 0 9 c c mono terpene *from charas, no effect*

9 Aug 2, 1897, Airedale terrier, 1 1 c c sesqui terpene from charas, no effect

10 Aug 3, 1897, Airedale terrier, 0 5 g cannabinol distilled at 406 degrees C (atmospheric pressure), lay down (30 m), vomited (55 m), depressed, head falling to one side (75 m), afterward sleepiness, unsteadiness, etc, vomited twice (6 h), effect almost as marked as 4

11 Aug 11, 1897, Airedale terrier, 1 c c greenish oil, intermediate between sesqui terpene and cannabinol, unpleasant smell, vomited (45 m), no effect beyond slight depression

12 Oct 19, 1897, Airedale terrier, 9650 gms, , 9 97 g intermediate product between sesqui-terpene and cannabinol (distils below 300 degrees C), slight depression, increased micturition, otherwise normal

13 Fox terrier, 7550 gms, 0 75 g intermediate product between sesqui terpene and cannabinol (distils below 300 degrees C), vomited four times (70 to 100 m), increased micturition, no other effect

14 Oct 27, 1897, Airedale terrier, 10,700 gms, 1 15 g cannabinol, from Merck's cannabinon, depression (40 m), sleepiness, *muscular weakness and unsteadiness, dilated pupils*, vomiting (140 m, 240 m, 255 m), somewhat better, but still severely affected (5½ h), would not touch food, apparently well next morning Most marked effect yet

15 Fox terrier, 7950 gms, 1 04 g cannabinol, from T and H Smith's cannabin Unsteadiness (35 m), which increased, became tired and sleepy but walked about much, vomited (4 ¼h), more unsteady but less depressed than other dog, would not touch food, well next morning

16 Nov 11, 1897, Airedale terrier, 11,250 gms, 0 99 g Merck's cannabinon No effect (30 m), usual symptoms marked (60 m), continued to 180 m, afterward gradual improvement, very much better (6½ h) salivation (2 h, continued 1 h), vomiting (2 h), depression and unsteadiness more marked than 14 but more transient

17 Fox terrier, 8100 gms, 1 04 g ext cannab indic ether (Merck) Slight effect (60 m), unsteadiness (75 m), vomited (3½ h), ataxia main symptom, not much better (6½ h), very little sleep, apparently well next morning, effect about the same as 15

18 Nov 18, 1897, Airedale terrier, 0 19 g ext cannab indic ether (Merck) Depression (45 m), marked unsteadiness (60 m), slight salivation (90 m), sleepy, excited, vomited (3 h), ataxia not much better when left (4 h)

19 Nov 22, 1897, Airedale terrier, 1 95 g cannabinol Slight effect (30 m) unsteadiness, sleepiness, etc, developed, but symptoms not more severe than 18

20 Fox terrier, 1 g ext 'cannab indic (Merck) Commencing weakness (45 m), more marked (60 m), afterward became very severe, incontinence of urine, vomited (130 m, 135 m), trembling from cold, slight improvement (3½ h)

11 Nov 26, 1897, Airedale terrier, 0 19 g cannabinon (Merck) given in a piece of meat Slight effect (2 h) distinct unsteadiness (2½ h), subsequently worse, depressed but not sleepy

22 Fox terrier, 0 55 g extract cannab indic Sicc (Merck) No distinct effect

23 Dec 1, 1897, Airedale terrier, 12,400 gms, 0 15 g alco

hol ether extract charas [previously heated three times with dil H_2SO_4] Sleep main symptom, depression (60 m), unsteadiness (90 m), vomiting (2½h 3½ h), distinct improvement (5 h)

24 Fox terrier 8800 gms , 0 15 g alcohol ether extract charas [previously heated three times with dil H_2SO_4] Slight depression (35 m), slight unsteadiness (75 m), afterward very distinct, slept, salivation (3 h), vomited (4 h), not much improvement (6 h), well next morning

25 Dec 3, 1897, Airedale terrier, 0 15 g alcohol ether extract charas [previovsly heated 14 hours at 260 degrees C] Effects similar to 23, but somewhat less marked and delayed—no obvious action except slight depression and sleepiness for three and one half hours

26 Fox terrier, 0 21 g alcohol ether extract charas [previously heated 14 hours at 260 degrees C] Slight depression (60 m), slight unsteadiness (3 h), much more marked (3½ h), improvement (4½ h)

27 Dec 6, 1897, Airedale terrier, 0 15 g cannabinol rapidly distilled from alcohol ether extract No apparent effect (70 m), later, usual symptoms developed, very distinct unsteadiness

28 Fox terrier, 0 54 g pitch from extract, contains a little cannabinol Slight depression, no other distinctive action

29 Dec 9, 1897, Airedale terrier, 0 15 g distillation fraction previous to cannabinol than latter Depression (30 m), sleepiness, unsteadiness (85 m), but not marked, attention good, excited (5½ h)

30 Fox terrier, 0 21 g distillation fraction previous to cannabinol than latter Mostly laid down at first, slight unsteadiness (2 h), worse (3½ h), slight sleepiness, symptoms not marked

31 Airedale terrier, 0 21 g charas extract, further heated for 60 hours at 220 to 260 degrees C (cp 25) Depression (60 m), unsteadiness (105 m), slept fairly well, much better (5½ h), symptoms more marked than 25 but less than 23

32 Fox terrier, 0 39 g charas extract, further heated for 60 hours at 220 to 260 degrees C (cp 25) Slight depression and unsteadiness (90 m), much more marked (2 h), still severe (5½ h), sleepy, symptoms about equal to 24

33 Dec 28, 1897, Airedale terrier, 1 07 g cannabinol (oldest) Laid down at first, could not be induced to stand long, very slight unsteadiness (3 h) and depression, more severe (5 h) but still fairly well, normal next morning

34 Fox terrier, 1 03 g cannabinol (oldest) Slight depression (60 m), unsteadiness (90 m), still distinct (5 h), depressed following morning

35 Dec 29, 1897, Airedale terrier, 0 92 g cannabinol, distilled from another sample of charas Asleep (55 m), very unsteady (90 m), continued as long as observed (6 h), slept mostly

36 Fox terrier, 0 96 g cannabinol, distilled from another sample of charas Unsteadiness (55 m), became very marked afterward, vomited (65 m and 5 h), slight improvement (6 h)

37 Dec 31, 1897, Airedale terrier, 1 1 g cannabinol (oldest) Slight depression and unsteadiness (70 m), increased later, slept mostly, more marked effect than 33

38 Fox terrier, 0 97 g cannabinol (oldest) Unsteadiness (70 m), which increased, still marked (5½ h), effect greater than 34

39 Jan 3, 1898, Airedale terrier, 0 97 g cannabinol, distilled from another sample of charas No effect (60 m), afterward slept, very slight unsteadiness, (2 h), did not increase, lay down occasionally, slept remainder of day, playful when aroused

40 Fox terrier, 0 95 g cannabinol, distilled from another sample of charas No effect (60 m), very slight unsteadiness (2 h), soon became more marked continued as long as observed, slept somewhat slightly depressed next morning

41 Jan 4, 1898, Airedale terrier, 1 1 g cannabinol, distilled from another sample of charas Slight depression, no marked symptoms

42 Fox terrier, 0 99 g cannabinol, distilled from another sample of charas Depression and unsteadiness (2 h) not very marked, slight depression next morning

43 Jan 5, 1898, Airedale terrier, 12 110 gms 1 03 g cannabinol distilled from another sample of charas Slight depression (60 m), slight unsteadiness, slept mostly, unsteadiness increased, vomited (125 m), awakened to be taken to kennel, very unsteady

44 Fox terrier, 8210 gms , 0 97 g cannabinol, distilled from another sample charas Slight depression and unsteadiness (60 m), became more marked and continued as long as under observation (6½ h), vomited a little (5¼ h), slept partly apparently normal next morning

45 Jan 6, 1898, Airedale terrier 1 01 g cannabinol, distilled from another sample of charas Slight depression (60 m), slept mostly, unsteadiness less marked than 43, apparently well the following morning

46 Fox terrier, 0 97 g cannabinol, distilled from another sample of charas Slight depression (60 m), unsteadiness (70 m), effects similar but ataxia less marked than 44

47 Jan 7, 1898, Airedale terrier, 0 98 g cannabinol, distilled from another sample of charas Slept most of the time, unsteadiness slight

48 Fox terrier, 0 97 g cannabinol, distilled from another sample of charas Depression (30 m), unsteadiness (60 m), became very distinct, laid down mostly, slept partly, very slight depression next morning

49 Jan 8, 1898, Airedale terrier, 1 04 g cannabinol, distilled from another sample of charas Depression (60 m), unsteadiness (90 m), not further observed

50 Fox terrier, 0 99 g cannabinol, distilled from another sample of charas No apparent effect (90 m), not further observed, apparently normal next morning

51 Jan 9, 1898, Airedale terrier, 1 02 g cannabinal, distilled from another sample of charas Not observed

52 Fox terrier, 1 g cannabinol, distilled from another sample of charas Not observed

53 Jan 10, 1898 Airedale terrier, 1 02 g cannabinol, distilled from another sample of charas Depression, distinct ataxia, but not marked, slept most of the time

54 Foxterrier, 1 g cannabinol, distilled from another sample of charas Sleepiness, depression and slight unsteadiness, symptoms less marked than usual, slight depression next morning

55 Jan 11, 1898, Airedale terrier, 0 22 g cannabinol (as 31) No evident effect (60 m), later transient depression, but no ataxia developed Compare with 31

56 Fox terrier, 0 4 g cannabinol (as 31) No effect (60 m), later depression and unsteadiness but less than 32

57 Jan 25, 1898, Airedale terrier, 13,150 gms , 0 21 g cannabinol (as 31) Slight depression (60 m), afterward sleepiness, unsteadiness, excited (5 h)

58 Fox terrier, 7980 gms , 0 42 g cannabinol (as 31) No effect (60 m), later sleepines, slight unsteadiness and depression

59 Feb 11, 1898, Airedale terrier, 0 16 g third fraction cannabinol dissolved in 64 g olive oil Depression (30 m) followed by sleep, no distinct unsteadiness, excited at times, vomited a little (4¼ h), still depressed (5¼ h)

60 Foxterrier, 0 18 g third fraction cannabinol dissolved in 64 g olive oil Depression (35 m) and sleep, no ataxia observed but could not be induced to stand long, still depressed (5 h)

61 Feb 15, 1898, Airedale terrier, 0 16 g second fraction cannabinol in 64 g olive oil Symptoms similar to 59

62 Fox terrier, 0 18 g second fraction cannabinol in 64 g olive oil Slight depression and unsteadiness (2½ h) but less marked than 60, vomited (5 h)

63 Feb 17, 1898, Airedale terrier, 0 16 g first fraction cannabinol in 64 g olive oil Depression somewhat more marked than 61 but no unsteadiness, vomited slightly (3 h)

64 Fox terrier, 0 18 g first fraction cannabinol in 64 g olive oil , Some depression and slight unsteadiness, but doubtful if as marked as 62

65 Feb 22, 1898, Airedale terrier, 0 21 g cannabinol distilled at atmospheric pressure, then heated 5 hours at boiling point Slight depression and sleepiness, no ataxia observed, much better (5½ h)

66 Fox terrier, 0 23 g cannabinol distilled at atmospheric pressure, then heated 5 hours at boiling point Slight depression, no sleep, almost well (5½ h)

67 Feb 24, 1898, Airedale terrier, 2 1 g cannabinol distilled at atmospheric pressure, then heated 5 hours at boiling point Depression and unsteadiness, but symptoms not very marked, slept somewhat, vomited (3½ h., 4½ h), slight improvement (6 h)

68 Fox terrier 2 2 g cannabinol distilled at atmospheric pressure, then heated 5 hours at boiling point Depression and distinct unsteadiness, did not sleep, somewhat better (5½ h)

69 Feb 28, 1898, Fox terrier, 0 43 g acetyl derivation of higher homlogue of cannabinol No effect (2½ h)

70 March 1, 1898 Airedale terrier, 0 2 g cannabinol distilled in vacuo Depression sleep and unsteadiness, more marked than 67, decided improvement (5½ h)

71 Fox terrier 0 22 g cannabinol distilled in vacuo Distinct unsteadiness (60 m) slight depression symptoms similar to 65, much better (5½ h)

72 March 3, 1898, Airedale terrier 0 45 g pitch dissolved in 1 5 g olive oil containing some cannabinol Slight depression and unsteadiness, much better (4½ h)

73 Fox terrier, 1 03 g cannabinol regenerated from old acetyl compound Slight depression and sleepiness, no obvious ataxia

74 March 8, 1898, Airedale terrier, 0 06 g morphin acetate in capsule Vomited frothy mucous like vomit (12 m , 14 m , 17 m), marked depression, much worse than any previous observation, retching (22 m), rapid breathing, quick pulse, head nodding (40 m), salivation (44 m , continued to 120 m), still much depressed, constant moaning, slight myosis (130 m), fall of temperature 1 1 degrees C , sleepiness, slight unsteadiness, improvement (4 h), but still depressed (5½ h)

75 Fox terrier, 0 1 g morphin acetate in capsule No effect (20 m), head nodding (30 m), retching and vomiting of frothy colorless fluid (35 m , 38 m , 50 m , 55 m , 90 m , 105 m), salivation, unsteadiness, depression (130 m), not sleepy, salivation stopped (3¼ h), fall of temperature 2 3 degrees C, could not be induced to stand up, somewhat better (4½ h)

76 March 16, 1898 0 93 g olive oil extract of charas, containing about 2 to 25 g soluble charas products Slight depression and unsteadiness (60 m), sleepiness, vomiting (160 m), ataxia more marked, excited (3½ h), slight improvement (5¾ h)

77 Fox terrier, 1 86 g olive oil extract of charas, containing 4 to 5 g soluble charas products Sleepiness and depression (30 m), distinct unsteadiness (60 m), which became more marked later, vomited (105 m), no obvious improvement (5¾ h)

78 March 18, 1898, Fox terrier, 8840 gms , 0 15 g extract cannab indic (B P) in pills (from London chemist) No effect (90 m), afterward depression and marked ataxia, vomited (2½ h)

79 March 22, 1891, Airedale terrier, 13,580 gms , 1 03 g partly (¾) saponified acetyl derivative of higher homologue of cannabinol No distinct effect

80 Fox terrier, 0 35 g oxycannabinol No obvious effect

81 March 25, 1898, Airedale terrier 1 02 g cannabinol Depression, very distinct unsteadiness (60 m), sleepiness, vomited (2 h , 3¼ h) no distinct improvement (4¼ h)

82 Fox terrier, 0 99 g cannabinol No obvious effect (60 m), depression (75 m), vomiting (105 m,, 115 m , 130 m , 135 m , 255 m), slight unsteadiness (120 m), symptoms increased, no improvement (4½ h)

83 March 30, 1898, Airedale terrier, 1 g chloral hydrate in capsule Sleepiness (15 m), very slight ataxia, somewhat more marked (30 m), fall of temperature 0 4 degrees C , apparently normal (4h)

84 Fox terrier, 1 g chloral hydrate in capsule Sleepiness (15 m), slight muscular weakness but no distinct ataxia, fall of temperature 0 4 degrees C , apparently normal (4 h)

85 April 5, 1898, Airedale terrier, 0 5 g chloralose in capsule Slight depression and sleepiness, transient, fall of temperature 0 5 degrees C

86 Fox terrier, 0 0195 g hyoscine hydrochlorid Uneasiness (30 m) followed by whining, dryness of the tongue, dilatation and less marked reaction of pupils to light, increased rapidity of heart beat (60 m), improvement commenced (2 h), no fall of temperature

87 April 11, 1898, 0 21 g cannabinol Slight depression, sleepiness and unsteadiness, continued 6 hours

88 Fox terrier, 0 2 g cannabinol Slight depression (30 m) but not much affected until (90 m), became very unsteady, sleepiness, incontinence of urine, trembling, vomiting (2 h), fall temp 3 degrees C , most marked effect obtained with this dose

89 English terrier, 7180 gms , 0 15 g cannabinol Less reserved (20 m), slight depression (30 m), sleepiness chief symptom, no obvious ataxia, slight improvement (5 h)

90 April 15, 1898, Airedale terrier, 0 2 g cannabinol kept in sealed tube since Dec 12, 1896 Slight depression and sleepiness (45 m), became much more marked, unsteadiness developed, attention became impaired, vomited (5 h), then improved

91 English terrier, 0 14 g cannabinol, kept in sealed tube since Dec 12, 1896 Slight depression and very distinct unsteadiness (30 m), gradually increased until fell over every few steps, vomited (100 m,, 104 m , 150 m , 200 m), slept a little (3½ h), much better but still markedly depressed (5 h , temperature fell 0 5 degree C, then rose 1 2 degree C

92 Fox terrier, 0 39 g cannabinol through which oxygen has been passed 3 to 4 hours at 150 degrees C Slightly depressed (45 m), very slight unsteadiness (60 m), became somewhat more marked, slight sleepiness, symptoms not severe but temperature fell 1 4 degrees C

93 April 19, 1898, Airedale terrier, 12,840 gms , 0 22 g cannabinol (as in 90), subjected to oxygen for 6 hours at 150 to 160 degrees C Slight depression and sleepiness (30 m), increased, distinct unsteadiness, not much improved (6 h)

94 English terrier, 0 16 g cannabinol (as in 93) Depressed, restless (20 m), sleepy (30 m), slight unsteadiness (40 m), gradually became worse, but not so bad as in 91, vomited (55 m , 115 m), somewhat better (4½ h), but no further improvement (5¾ h)

95 Fox terrier, 8270 gms , 0 21 g cannabinol (as in 90) Slight depression (30 m), but not much affected during first hour, afterward much depressed, slight unsteadiness, no improvement (5¾ h)

96 April 23, 1898 Fox terrier, 0 19 g cannabinol (as in 90) Asleep (30 m), but no marked symptoms for three hours, then slight unsteadiness, which increased, distinct (6¼ h)

97 Airedale terrier, 0 22 g cannabinol through which CO_2 has been passed for 20 hours at 150 to 185 degrees C Slight depression and sleepiness (30 m) became more marked, unsteadiness (60 m), vomited (105 m), afterward improved but still under influence (6¼ h)

98 English terrier, 0 2 g cannabinol through which oxygen has been passed for 20 hours at 150 to 185 degrees C , pitchy appearance Very slight depression and restlessness (30 m) which quickly (1 h) passed away, no ataxia

99 April 27, 1898, English terrier, 7760 gms , 0 2 g tribromcannobinol Depressed (60 m), slight sleepiness but no distinct unsteadiness, apparently normal (4 h)

EXPERIMENTS ON CATS

100 Dec 11, 1895 2500 gms , 3 5 g charas given in mucilage (65 c c), chloroformed during injection Vomited most of the substance (about 50 c c) after recovery from chloroform, depression, weakness, narcosis and death (4 h), no characteristic macroscopic changes

101 June 20, 1896, 2600 gms 0 15 g cannabinol in meat, Sleepiness (90 m'), muscular weakness, marked ataxia, stupidity, commencing improvement (25 h), complete recovery (44 h)

102 May 26, 1896, 2700 gms , same cat, 0 27 cannabinol as pills with starch Quiet (90 m), restlessness and micturition, then salivation (3½ h), muscular weakness and unsteadiness, anorexia, improvement (25 h), almost well (28 h)

103 June 2, 1896, 1 3 g cannabinol in capsules Tired, quiet (60 m), salivation and unsteadiness (100 m), marked ataxia sleepiness, dilated pupils improvement (30 h), almost well (53 h)

EXPERIMENTS ON RABBITS

Substances were made into an emulsion with gum and injected through a catheter into the stomach

104 Nov 1, 1895, 1730 gms , 0 895 g impure (sesqui) terpine Slight excitement

105 Nov 4, 1895, 1730 gms , 0 895 g charas with sodium bicarbonate Slight excitement

106 Nov 5, 1895, 1730 gms 0 876 g petroleum ether extract Slight excitement

107 Dec 17, 1895, 1440 gms , 1 44 g charas No distinct effect

108 Jan 16, 1896, 1500 gms , 3 g petroleum ether extract Became quieter, number of heart beats and respiration, and temperature fell, death occurred on third day

109 June 5, 1896, 1100 gms , 2 2 g cannabinol Depression (60 m), sleepiness, fall in pulse (252 to 100), respiration (142 to 18) and temperature (40 4 to 35 7 degree C), diminished reflexes, improvement (20 h), much better but not normal (29 h)

110 June 10, 1896, 930 gms , 2 2 g charas Quieter (90 m), fall in pulse, respiration and temperature, died on fourth day, cold and marasmus

11 April 5, 1898, 620 gms , 2 3 g cannabinol Depressed, slight muscular weakness, sleepiness, fall in pulse, respiration and temperature, death, 3½ days

PERSONAL EXPERIMENTS

112 Feb 19, 0 1 g cannabinol, taken about 2 45 P M

113 Feb 8, 1896, 0 1 g cannabinol in 0 05 c c alcohol and 20 c c water Slight mental depression

114 March 9, 1895, 0 5 c c monoterpene in 20 c c water No effect

115 March 10, 1896, 0 05 g cannabinol in 0 1 c c alcohol and 20 c c water No distinct effect for 4 hours, then feeling of dryness in mouth, pleasant tingling, slight unsteadiness, happiness, unpleasant visions on closing eyes, time relation not completely lost, feeling of tiredness but no marked tendency to sleep

116 March 28, 1897, 0 05 g cannabinol regenerated from acetyl compound Taken at 8 P M , retired to bed at 10 30 feeling a little tired, slept soundly till 6 P M no distinct effect

117 April 5, 1897, 0 05 g cannabinol regenerated from acetyl compound Taken at 10 30 A M , slightly depressed in afternoon, no other effect

118 April 5, 1897, 0 1 g cannabinol regenerated from acetyl compound Taken at 11 A M, tired and sleepy in afternoon

119 April 10, 1897, 0 2 g cannabinol regenerated from acetyl compound Taken at 1 P M, slight dryness of mouth and paresthesia (160 m) followed by sleepiness, depressed during evening retired at 11 30

120 April 13, 1897, 4 cannabinol tablets (a commercial preparation) = g cannabinol Taken at 5 08 P M, feeling of lightness in head (5 55), dinner 6 00, afterward felt sleepy and slightly intoxicated, time relations altered but not annulled

121 June 7, 1897, 0 2 g cannabinol phosphate Taken at 10 30 P M, Retired at 12 M no evident effect

122 June 9, 1897, 0 4 g cannabinol phosphate No distinct action

123 June 6, 1897, 0 8 g cannabinol phosphate Taken at 10 45 P M, 11 40 very sleepy retired, awoke at 7 20 A M, feeling very sleepy, depressed all the morning

124 March 17, 1898, 0 05 g oily extract of charas, containing 013 g soluble products Dinner at 6 20, taken at 8 00, slight sleepiness and mental exhaustion followed

125 March 18, 1898, 0 105 g oily extract of charas, containing 0 13 g soluble products Taken at 6 25 P M, dinner 6 50, 7 35 peculiar feeling of lightness in head, continued to work, 8 00 rather better, 11 00 retired feeling sleepy

126 March 20, 1898, 0 016 g (¼ grain) ext cannab Ind (B P) pill Tea 5 P M, slight indigestion, pill taken at 7 30, 10 30 no evident effect, 10 35 slight light headedness, warmth of face and mental exhaustion, afterward fell asleep

127 March 21, 1898, 0 14 g partly (¾) saponified acetyl derivative of higher homologue of cannabinol Taken at 5 30 P M, no effect

128 March 22, 1898, 0 1 g third fraction cannabinol Taken at 5 45 P M, dinner 6 30, 8 25 feeling of lightness in head and mental exhaustion, continued working, effect passed off in about 30 m

129 March 23, 1898, 0 1 g second fraction cannabinol Taken at 5 45 P M, dinner 6 45, 7 20 no effect, 9 25 slight dryness of lips and lightness in head, seemed to pass off but worse again at 7 43, happy, have difficulty in reading, sleepy, 10 00 just awakened from a short nap, read a little but soon exhausted, 11 20 retired, 6 45 A M awoke, felt well

130 March 24, 1898, 0 1 g first fraction cannabinol Taken at 5 45 P M, dinner 6 45, 7 45 no effect, 7 50 feeling of slight dryness of lips and lightness of head, 8 00 somewhat more depressed, not working well, 8 45 working better 10 00 still somewhat depressed, 11 30 retired but did not succeed in sleeping for some time

131 March 25, 1898, 0 1 g cannabinol (oldest) Taken at 5 45 P M, dinner at 6 30, 7 30 peculiar light-headedness and dryness of the lips, 7 45 slightly unsteady, parasthesia in head and legs, heaviness of eyelids, no correct estimation of time, 9 30 awakened from short sleep, 10 00 rather better but unable to work, 10 30 retired, somewhat depressed the following morning

132 March 27, 1898, 0 35 g acetyl derivative of higher homologue of cannabinol Taken at 7 30 P M, no effect

133 March 29, 1898, 0 05 g cannabinol pill made 18 months ago Taken at 5 50, dinner at 6 30, 8 30 unsteady symptoms, cannot work, estimation of time not so good, 9 15 worse energyless 10 30 went out for few minutes, improved, 11 00 can read moderately well but eyelids heavy

134 March 30 1898, 0 09 g Merck's cannabinon Taken at 5 45, dinner 6 30, 7 20 lightness in head, loss of time relation, happy, amused, pleasant tingling, etc, sleepy, 8 00 lay down slept till 10 30 then retired, awakened (7 00 A M) feeling dull and depressed, lasted the whole morning

135 April 14, 1898, 0 05 g opium Taken at 9 00 P M 10 00 no obvious action, 10 05 slight heaviness of eyelids, very slightly tired, 10 20 rather better, 11 10 feel somewhat tired, head rather heavy, slight sense of "well being," 12 00 still heaviness of eyes and tiredness of head but have worked fairly well last half hour, not sleepy, retired, soon fell asleep awakened at 7 00 A M feeling well pleasant sense of gravity, which continued most of morning, no constipation

136 April 15, 1898, 0 1 g cannabinol through which oxygen passed 3 to 5 hours at 150 to 160 degrees C Taken at 5 45, dinner at 6 30, 9 15 slight visual indefiniteness, slight and transient paresthesia, afterward felt slight incapacity for work but no marked effects 11 45 not sleepy but retired

137 April 17 1898, 0 05 g cannabinol sealed up since Dec 28, 1896 Tea 4 30, drug taken 5 45, 6 50 slight mental exhaustion and feeling of lightness in head, 7 20 rather sleepy 8 00 trying to read but have little energy for anything, 9 00 condition same, no estimation of time, feeling of warmth in face and head 10 00 sleepy, retired

138 April 21, 1898, 0 065 g same cannabinol treated with oxygen for 20 hours at 150 to 185 degrees C Taken at 5 45, dinner 6 40, 8 05 slight feeling of lightness in head, 9 30 have been reading some time, at first had a little difficulty, now feel quite normal

139 April 22, 1898, 0 05 g same cannabinol treated with CO_2 for 20 hours at 150 to 185 degrees C Taken at 5 50, dinner 6 30, 7 00 commencing light headedness, 8 00 more distinct, a want of energy 9 45 condition same, trying to read, 10 00 not able to do any work, 10 45 no improvement, retired

140 April 24, 1898 0 1 g tribrom cannabinol Taken at 8 00 P M, supper at 8 30, 9 30 slightly sleepy, 11 00 sleepy, no other peculiar effect of cannabinol, retired, slept till 6 45, depressed, suffered from mental exhaustion during three following days

141 May 4, 1898, 0 065 g oxycannabinol (as in 138) dissolved in oil Taken at 5 45, dinner at 6 30 7 15 went out for a walk, 8 15 arrived home slightly tired, peculiar feeling in eyes and head grew slightly worse and continued the whole evening, but was insufficient to prevent me writing, 11 10 retired, slept soundly, 6 40 A M got up, felt sleepy

142 May 6, 1898, 0 1 g charas (best) Taken at 5 45, tea at 4 30, dinner at 7 00 7 00 slight effect in head, worked in garden, felt want of energy, 8 30 influence more marked, agreeable heaviness of eyelids, very little energy, 10 00 retired, condition same, slept well, depressed following morning

143 May 12, 1898, 0 016 g (¼ grain) ext cannab Indic (B P) in pill (cp 126) Taken at 5 50, dinner at 6 30, 7 25 lightness of head, peculiar feeling about eyes, 7 50 pleasant tingling in face and feet, no other marked effect, reading fairly well, 8 40 tingling still present, unable to read with benefit, can not calculate time very well, symptoms continued throughout evening, became sleepy but managed to do some copying, 12 30 retired, 7 30 got up feeling tired but soon well

144 May 19, 1898, 2 c c sesqui terpene taken in weak mucilage Taken at 12 45, lunch 1 10, 1 15 slightly listless and slight heaviness of head, which soon passed away

---

THE THERAPEUTICAL ECONOMICS OF OPEN COMPOSITION

Presented to the Section on Materia Medica Pharmacy and Therapeutics, at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo
June 7-10 1898

BY ALBERT B PRESCOTT, M D
ANN ARBOR MICH

There is only one restriction upon the character of medicines supplied to the public, to be expected at the hands of the law-makers in the period now before us, namely restriction, with the intent to put a stop to concealment of composition and identity That legal restriction to this effect may be instituted in some of the States at any time, and is likely to become prevalent, appears manifest from the temper of the law-making mind, shown in various ways, especially in the scope of the enactments against adulterations Any alteration of composition is prohibited if it be not made known to the purchaser (or consumer), but is allowed if it be so made known Various irregular admixtures are specifically authorized upon the one condition that they shall be explicitly announced on the label On the other hand, various colorings and facings of food, which are harmless in themselves, are prohibited because they tend to deceive the consumer as to identity or quality of the article The same intent appears in legal rulings for uniform standards of concentration of foods and of medicines, and it appears in the early requirements of poison-labels, lately extended, in some instances, to proprietary mixtures sold without a physician's order and without any account of contents

Granting that some of these prohibitory measures have been worked for as a means of protection to certain industries, and that in other cases the legislation has been proposed by unscrupulous persons, who seek opportunity to levy bribes, etc, it still remains true that the laws already enacted in this direction have been made possible by a prevailing conviction in the minds of common-sense people, holding as they do, the ultimate balance of power in legislation, that it is dangerous to leave covers of concealment over articles of medicine or food in the market The average intelligent citizen, and the average plain man of the law, when the question is put fairly before him, will say without hesitation that medicines sold in packages, without the direction of a physician, ought to be compelled by law to bear a statement of their contents in terms known to science This average man of sense will maintain that it is no affair of the State whether an article of medicine purchased in the market be pharmacopeial or not, made by patented or concealed processes or not, trade-marked by a proprietor or not, monopolized in production or not, but that it does matter to the man who is to take the article of medicine or give it to his child, whether or not he shall be informed what the article really is, in terms such as any physician or pharmacist could define and interpret, and furthermore, that the right of the man to this information might well be made an affair of the State In fact, the layman is likely to enforce a classification of therapeutic agents, more simple than any of the systems known in pharmacology, a mere division of medicaments into the knowns and the unknowns And legislative enactment is more than liable to separate the one of these divisions from the other "as a shepherd divideth his sheep from the goats," when these matters are brought into judgment

With this outlook, therefore, the concern of this brief paper is not one of professional ethics, but rather one of social economics Neither the physician nor the pharmacist has any economic interest in the use of secret remedies, or any reason to delay prohibitory measures against secrecy of composition The custom of medication by remedies named from the diseases they are alleged to cure is a custom that has no actual use for pharmacists or physicians at all

The physician within whose function it falls to select remedies and confine their application to certain needed results, may, in his discretion, either countenance or discountenance secrecy of composition He is liable to think little of his responsibility in this matter, because while he is acting as an expert for his patient the latter has no need to be informed of the contents of medicinal mixtures For his own judgment, the physician may believe himself able, in some cases, to arrive at the character of a medicine without a statement of its contents, and may avail himself of the convenience of a ready-made secret mixture, which thenceforth holds the benefit of his approval

The pharmacist, on the contrary, is not to judge of the selection and application of remedies of his own knowledge as an expert, neither is he to question his patron's choice among various systems of medication So long as articles of concealed composition are not made contraband in law, it is difficult for the pharmacist to refuse to furnish them, especially difficult when they are directed by physicians He can only do so upon the ground that such articles can not be made subject to record, as to the identity and quantity of the distinct agents they contain, therefore, he can have no check upon them and will not supply them

While secret medicines are tolerated by the laws, the physician or the pharmacist has but limited responsibility for their use, little influence as to their employment one way or the other If he do not go beyond his proper province, the secrecy of remedies is not of his doing, nor can he stop the use of these articles by the people. But both the physician and the pharmacist have marked influence, as authorities in regard to medicines in use, and have influence upon law-makers as to legislation in the question of open composition by the demand of the law

A policy of prudence, and of courage as well, with a careful study of the bearings of every legal provision proposed on the part of the staunch men of medicine and of pharmacy, can do most effective service in behalf of better economies in medication

THE MODERN INTESTINAL ANTISEPTICS AND ASTRINGENTS

Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo , June 7-10 1898

BY WM FANKHAUSER, M D

NEW YORK

The last decade has been very fruitful as regards the introduction of intestinal antiseptics and astringents To comprehensively describe each and every one introduced during this period, would be beyond the scope of a paper the reading of which will not prove tiresome to the listeners I will therefore confine myself to those which have made their first appearance during the past five or six years The modern intestinal antiseptics and astringents belong chiefly to one of two classes of preparations derivatives of tannic acid, or salts of bismuth The former will be alluded to first, the articles being described in the order of their introduction into the materia medica

Among internal astringents tannic acid has long occupied a prominent position, but it has a number of serious drawbacks, chief among which is that it acts undesirably on the mucosæ of the mouth and stomach, where the larger portion of its effect is expended before the remedy reaches the intestines Prolonged administration of tannic acid, furthermore, is known to be productive of gastric disturbances—anorexia, pain, nausea, and even vomiting With a view to obviating these disadvantages, experiments have been made with various derivatives of tannic acid, resulting in the production of a number of eligible compounds

Tannin albuminate was the first preparation introduced, which has a less disagreeable taste than the acid itself and acts less vigorously on the stomach, but, owing to the fact that it is largely absorbed in the latter organ, its astringent action becomes to a great extent lost to the intestine, and for this reason the remedy has been practically abandoned as an antidiarrheal The dose in which it was given is from 5 to 20 grains, in cachets

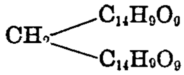
Tannigen was the next preparation brought forward which, with a few of its congeners since introduced, is not acted upon to any great extent in the stomach, and manifests its astringent action chiefly on reaching the slightly alkaline (in health, but in morbid conditions, vastly increased alkaline) secretions of the intestine, where a gradual and equable decomposition ensues and continues to the end of the gut Tannigen was introduced by Prof Hans Meyer of the University of Marburg, Germany, in the fall of 1894 (see *Deutsche Med Woch*, 1894, No 31) It is known, chemically, as diacetyltannin, and has the formula $C_{14}H_8(CH_3CO_2)O_9$ Its formation is based on the replacement of two hydrogen atoms of tannic acid by two molecules of acetyl It occurs as a light-gray, slightly hygroscopic, practically odorless powder, of a chalky and faintly astringent taste, soluble in alcohol, and in dilute solutions of the alkalies or their phosphates and carbonates, insoluble in cold water and in diluted acids

The first to put tannigen to a clinical test was Prof F Muller of Marburg (*Deutsche Med Woch*, 1894, No 31) He found it specially serviceable in chronic intestinal catarrhs, in which improvement was noted, usually in a short time, from doses of from 3 to 8 grains three times daily The next report was from Carl Künkler of Bonn (*Allgemein Med Central-Zeitung*, 1894, Nos 13 and 14), who used tannigen in some forty cases, covering chiefly chronic diarrheas of various origins and occurring mostly in children To adults he gave 3 to 8 grains, to children 1½ to 3 grains, three or four times a day The results as a rule were highly satisfactory, and in some cases a prompt cure was effected It is advised to continue the administration of the tannigen for some time after the disappearance of the catarrhal symptoms, to guard against relapses D De Buck of Ghent reports (*Belgique Médicale*, 1895, No 37) prompt results from tannigen in acute inflammatory conditions of the intestine, and a beneficial though less speedy effect upon chronic catarrhs Prof Escherich, of the Pediatric Clinic of the University of Graz, gives a detailed report (*Ther a Woch*, March 9, 1896) of his experience with tannigen His results are described as excellent in subacute and chronic intestinal catarrhs of children, characterized by mucous stools In the former category of cases often as early as on the second day of treatment, there was a marked diminution in the quantity of the mucus in the stools, and in a few, after several days the evacuations assumed a normal character In the chronic cases no such remarkable results were obtained, yet, in the commencement of the treatment at least, the decrease of mucus and the dry character of the passages was always noted It goes without saying, that an appropriate dietary was strictly observed in every instance In acute intestinal catarrh, with watery, projectile stools, as well as in the beginning of follicular enteritis, the results were inferior to those of calomel and bismuth subnitrate As regards administration, Escherich prescribed 4 grains in infants up to 1¼ years, and 8 grains to older children, from four to six times a day, mixed with the food Injurious after-effects, or disturbance of the appetite or digestion, were never observed Numerous additional reports are extant, chief among them being those of Richard Drews of Hamburg (*Allgemeine Med Central-Zeitung*, 1895, Nos 35 and 36), Professor Biedert of Hagenau (*Therapeutische Woch*, 1896, No 12), W Kölzer (*Jahrbuch für Kinderheilkunde*, 1898, pages 280-370), and the American physicians, G A Hewitt of Philadelphia (*Medical Bulletin*, 1896, No 1), E W Bing of Chester, Pa (*Medical Times and Register*, Sept 22, 1893), and H A Griffin and V H Norrie (*Daily Lancet*, March 30, 1896)

The writer has found tannigen a mild yet efficient antidiarrheal in catarrhal enteritis and in catarrh of the large intestine, particularly when characterized by copious mucous dejections As a rule, untoward effects were not observed At times tannigen leaves a strongly astringent sensation in the mouth, which renders it impossible to administer the remedy to some children, then again, it is occasionally vomited by sensitive children The simultaneous administration of pepsin often corrects this In the writer's opinion tannigen is contraindicated in pronounced inflammatory diseases of the intestine accompanied by profuse effusion of serum into it In cases of the secretion of a thin, serous fluid, such as results from acute irritation of the upper part of the intestinal canal, it is of little service It is particularly the lower portion of the intestinal canal that reacts well to tannigen The amount of mucus is diminished at once, and its over-production does not recur unless the use of the remedy is discontinued too soon As a consequence, not only are the irritated state of the mucous membrane and the particular cause of the disease overcome, but the loss of the nitrogenous material and the heightened peristalsis are reduced, and the absorption of water and nutrient matter in the large intestine is promoted But this is not all that tannigen and its congener, tannalbin, accomplishes In spite of the paucity of clinical evidence, it can hardly be denied that tannin has a certain disinfectant power by impeding bacterial development, as with alkaloids, so with numerous bacterial poisons, such as toxalbumins, it unites to form insoluble, and consequently non-poisonous, compounds, as is shown in Cantani's treatment of cholera Tannigen occasionally colors the stools black

As regards dosage, large quantities are preferable and more reliable, for children under one year of age, up to 4 grains every two hours for a few doses and then from four to six times a day, for older children, from 5 to ten grains, and for adults 15 grains, or even a few 30-grain doses followed by 15-grain ones every four hours Tannigen has a tendency to "cake", hence it is best to dispense it with, say 1/10 its weight of silica or some other insoluble and inert substance In painful conditions 1 grain of powdered opium, or, in cases where this drug is illy borne, ¼ grain of codein, is a necessary addition, for tannigen and its congeners of the tannin series are not capable of arresting severe pain or violent tenesmus It is best taken, triturated as above indicated, in a little glycerated, freshly boiled water

Tannoform was the next tannin derivative brought forward, a condensation product of formaldehyde and nutgall tannin Chemically it is methylene digallate, and its composition is represented by the formula



$$CH_2 \begin{cases} C_{14}H_9O_9 \\ C_{14}H_9O_9 \end{cases}$$

It occurs as a pinkish, light, odorless, tasteless powder, insoluble in water or acidulated fluids, but soluble in alcohol, ammonia water, and sodium hydroxide or sodium-carbonate solution

Tannoform was introduced by Prof J von Mering (*American Medico Surgical Bulletin*, 1896, p 137) as a remedy for hyperidrosis, bromidrosis and "weeping" eczema The physiologic fact that the preparation is but slightly attacked by the gastric juice and decomposed into its components chiefly on reaching the intestine, led to its employment also internally, as an intestinal disinfectant and astringent Von Mering found tannoform quite effective, particularly in chronic catarrhs and De Buck and De Moor substantially confirmed his results (*Belgique Médicale*, 1896, No 33) These clinicians employed doses of 8 grains three or four times a day, to children 4 grains was given with an equal quantity of peppermint-oil-sugar, and taken with tea, milk or chocolate

Though recommended by the above-quoted authorities in chronic intestinal catarrhs, tannoform does not appear to have been employed to any great extent in the capacity of an anti-diarrheal The next report on it appeared first in the summer of 1897 It was by M Eberson of Tarnow, who used the remedy with success in 15 cases of chronic intestinal catarrh (*Aerztlicher Centralanzeiger*, 1897, No 26) Carl Sziklai (*Therapeutische Woch*, 1897, No 41) reported having used tannoform in 40 cases of intestinal catarrh in children, with failure in but one case Considerably smaller doses were employed than von Mering had advised, 1/6 to 3/8 grain every two hours The only other clinical report extant is by J Braun of Mokrin, who detailed his results in acute diarrheas of children, and in simple and tuberculous diarrheas of adults (*Therapeutische Woch*, 1897 No 46) In the former cases he gave 8 grains every two hours until relieved, and to adults 15 grains was administered four or five times a day Braun highly lauds the action of the remedy, without referring to any untoward accessory influence of the medication Prof R W Wilcox stated editorially in a recent issue of the *American Journal of the Medical Sciences* that his observations seem to indicate that tannoform is too irritating for internal use, and this opinion the writer shares Tannoform appears to decompose partly in the stomach, in pathologic conditions of the gastro intestinal tract, and the liberated formaldehyde in its nascent state is calculated to irritate the gastric mucosa Tannoform had best be confined to external application, and the writer of this paper can warmly recommend it as an efficacious antihidrotic and siccative antiseptic

Tannalbin was the next tannic acid compound introduced as intestinal astringent It is tannin albuminate rendered insoluble in the gastric juice by heating it at a temperature of about 120 degrees C, and washing the resulting product with diluted hydrochloric acid and with alcohol It occurs as a light-brown, odorless, tasteless powder, containing approximately 50 per cent of tannin It is insoluble in water or acidulated fluids, but soluble in alkaline solutions Of the various newer intestinal astringents tannalbin has been the most extensively reported on, and appears to be the ideal form of tannic acid for internal administration in inflammatory affections of the intestines The advantages claimed for it over uncombined tannic acid by the first investigators of its physiologic action—insoluble in the gastric juice of normal stomachs, and consequently causing no disturbance of that organ, slowly and equably decomposed by the intestinal fluids, thus manifesting its astringent action gently but persistently throughout the entire intestinal canal—seem to have been fully confirmed by extensive clinical experience, and the writer can unqualifiedly recommend tannalbin in all cases of intestinal trouble where tannic acid is indicated and calculated to be of benefit Tannalbin was introduced into therapy by Prof R Gottlieb of the Pharmacologic Institute of the University of Heidelberg, in the spring of 1896, and first employed clinically by R Von Engel, senior physician of the Moravian Provincial Hospital in Brünn, Austria, who reported his results in 40 cases in the *Deutsche Med Woch*, 1896, No 11 An excellent effect was observed in the entire group of chronic intestinal affections, and the results obtained in simple catarrhs of two to seven weeks' standing are designated as surprising In such cases from 45 to 60 grains per day for a day or two, usually sufficed to check the diarrhea, after which daily doses of from 15 to 30 grains for a few days or weeks longer effected a permanent cure Of 12 patients with phthisis 11 were cured of the diarrheal complication, and of 10 cases of acute intestinal catarrh 9 were promptly checked by tannalbin In profuse acute diarrheas of a functional or catarrhal nature the remedy was given every two hours, or even every hour for three or four doses As a rule the treatment was continued for from two to four days, when the desired effect was usually attained In toxic or infectious enteritis, in dysentery and in cholera morbus, it had better be avoided Von Engel never observed disagreeable or injurious by effects, not even on continued large dosing for weeks nor did he notice any aversion to taking the tannalbin The form of exhibition was in powder without any vehicle The second clinical report on tannalbin is by Prof O Vierordt of the Medical Polyclinic of the University of Heidelberg, who used the remedy both in children and in adults in some 30 cases (*Deutsche Med Woch*, 1896, No 25) It was always gladly taken, and no effect on the tongue, the stomach, or the appetite occurred even on long continued dosage of 2½ drs daily Those cases were primarily selected which had not proven amenable to dietetic measures nor to the usual medication Most of these were subacute and chronic enteritic catarrhs, 5 were of tuberculosis, 6 of renal origin, 1 from pelvic sarcoma and 5 of acute enteritis In all these various diarrheas thorough and prompt antidiarrheal action was manifested by the tannalbin Its markedly distinctive feature, as compared with the older intestinal astringents, was found to be its equable and uniform action throughout the entire gut In view of his experience, Vierordt places tannalbin unconditionally ahead of all preparations, tannigen included As regards dosage, he recommends starting, in adults with from 8 to 15 grains four times a day, and to increase the dose rapidly after the first twenty-four hours if the action be found insufficient up to, say 30 grains per dose and 2½ drams per day When a sufficient action has been sustained uniformly for a number of days in simple enteric catarrhs, the daily amount may be gradually reduced, if the condition continues satisfactory, until nil is reached For children beyond the first year the smallest initial dose should amount to 15 grains a day Vierordt administered the tannalbin either between or immediately after meals, with a spoonful of sterilized water or milk, or with gruel T G Rey of Aachen, Prussia, is a strong believer in the powers of tannalbin (*Deutsche Med Woch*, xxxiii, page 46) He used it in 68 cases of diarrhea chiefly in children under two years of age, among them 33 cases of cholera infantum and 12 of acute catarrh of the large intestines In all the former the tannalbin was combined with frequent small doses of calomel (1/20 to 1/12 grain every two hours), to intensify the deficient antiseptic action of the tannalbin up to the requisite point and with this combination it is claimed every case of gastro enteric trouble in nursing infants can be positively cured, excepting, perhaps, certain peculiarly fulgurant attacks of cholera infantum and the tuberculous form of chronic enteritis A peculiar beneficial action of tannalbin on the stomach has been observed by Prof W H Porter (*Post-Graduate*, Nov ,1897) Its free administration will often arrest the superabundant outpouring of mucus, precipitating the mucus and thus destroying one of the favorable media for the growth of micro-organisms In this manner it very decidedly aids in overcoming the so-called hyperacidity of the contents of the stomach Among others who have reported on tannalbin the following may be mentioned K Holzapfel, of the Medical Polyclinic of the University of Strassburg (*Deutsche Med Woch*, 1896, No 50), Scognamiglio of Naples (*Wiener Medicinische Blatter*, 1897, No 2), Joseph Friedjung of the Pediatric Clinic of the University of Berlin (*Jahrbuch fur Kinderheilkunde*, xlv, No 1), J Czemetschka of the Medical Clinic of the University of Prague (*Wiener Med Presse*, 1897, No 22), Hans O Wyss, of the Children's Hospital of Hottingen, Zürich (*Correspondenzblatt fur Schweizer Ärzte*, 1897, No 15), L Roemheld, of the Pediatric Clinic of Professor Vierordt at the University of Heidelberg (*Munchener Medicinische Wochenschrift*), W Koelzer, of Professor Heubner's Clinic at the University of Berlin (*Jahrbuch fur Kinderheilkunde*, 1898, p 280), and the American physicians, Leonard Weber of New York (*Post-Graduate*, Nov , 1897), Max Einhorn of New York (*ibid*), T V Smith of Westfield, N J , and Hermann T Wolff of Marion, Texas

Tannalbin has met with more than ordinary attention and favor by the medical profession The writer has found tannalbin particularly efficacious in mucous catarrhs of the intestinal tract, and chronic catarrhs of the large intestines yield very promptly indeed Like tannigen, in acute infectious diarrheas, accompanied by profuse effusion of serum and severe tenesmus, tannalbin is likely not to prove effective alone, for it has not pronounced disinfectant power, nor has it, as is to be expected, any distinctly anodyne effect, in painful conditions, therefore, some codein or other opiate has to be associated with it Tannalbin, owing to its perfect insipidity, is willingly taken by the most sensitive patients, and in the writer's experience has never been productive of vomiting Tannigen, on the other hand, while practically equally efficacious, not infrequently leaves a strongly astringent sensation in the mouth, which renders it impossible to administer it to some children, and occasionally it provokes vomiting, an effect never observed by the writer to follow the administration of tannalbin It appears that tannigen is decomposed to an appreciable extent in the stomach, and in this way is quite apt, on being pushed or long continued, to induce gastric disturbance In certain chronic conditions the writer has given tannalbin daily for weeks without causing, as far as could be observed, any digestive derangement In infectious diarrheas of children, in which tannalbin or tannigen alone is not effective, good results can be obtained by a combination with the purely disinfectant remedies, betanaphthol benzoate (benzonaphthol) or calomel, the former in doses of from 1/20 to 1/10 grain As regards administration, tannalbin is best taken with glycerinated sterilized water

Tannopine, the newest tannin compound introduced as an intestinal astringent, is what was first called tannon It is a condensation product of three molecules of tannic acid and one molecule of hexamethylenetetramine (known by the various trade names "urotropin," ' formin," etc) It contains 87 per cent of tannin It is described as a grayish-brown, odorless, tasteless, non-hygroscopic powder, insoluble in the ordinary solvents and diluted acids, and slowly soluble in alkaline fluids, analogously to tannalbin The only clinical report thus far met by the writer is by E Schreiber, of Professor Ebstein's clinic in Gottingen (*Pharmaceutische Centralhalle*, 1897, p 839) In doses of 15 grains for adults and from 3 to 8 grains for children, three or four times a day, tannopin never produced untoward effects Good results were obtained specially in tuberculous enteritis, and next in order in subacute and chronic non-tuberculous intestinal inflammations, both in adults and in children Tannopin is decomposed more slowly by the intestinal fluids than is tannalbin or tannigen, and hence, it is claimed, exerts a more prolonged astringent effect on the intestinal mucosa At the time of this writing tannopin was not as yet obtainable on the American market

Tribenzoylgallic acid is probably the latest addition, in the line of purely organic compounds, to the ever-growing list of intestinal astringents It was introduced by W Cohnstein of Berlin, and has thus far been reported on only by W Koelzer (*Jahrbuch fur Kinderheilkunde*, 1898, pp 280 307), of Professor Huebner's Pediatric Clinic connected with the University of Berlin The new substance is described as colorless (or white), odorless and tasteless, insoluble in water, but readily soluble in hot alcohol or in alkaline solutions It appears to be unaffected by keeping or by the saliva or gastric juice, for it reaches the intestines, when the stomach is in a normal condition, practically undecomposed, and is there disassociated, gallic acid being liberated and exerting its specific astringent action, while the rest remains physiologically inert According to Koelzer, tribenzoylgallic acid acts similarly to tannalbin and tannigen, but in a lesser degree He administered the remedy to infants in doses of 15 grains four times a day, and at times he even gave single doses of 30 grains repeated once or twice at two hour intervals The writer has not had an opportunity to test tribenzoylgallic acid, as the remedy was not obtainable on the American market at the time of writing, and the chemico physical description above given is taken from the preliminary announcement of the manufacturer This ends the list of the tannin derivatives introduced as intestinal astringents and antiseptics during the last decade

Bismuth subgallate, also known as "dermatol,' is the first of the various bismuth compounds to receive our attention It is a basic gallate of bismuth of the formula $Bi(OH)_2 C_7H_5O_5$ It occurs as a canary-yellow, heavy, odorless, non-hygroscopic, almost tasteless powder, containing 55 per cent of bismuth oxid It is insoluble in the ordinary solvents, but dissolves in sodium hydrate solution without separation of bismuth hydrate, which behavior distinguishes it from other bismuth salts Bismuth subgallate does conglutinate and get lumpy, and is indifferent to light and air Though first described in 1841, bismuth subgallate was not employed therapeutically until 1891, when Heinz and Liebrecht (*Berliner Klin Woch* , 1891, No 24) recommended it as a substitute for iodoform externally, possessing the antiseptic and siccative action of the bismuth salts and the reducing action of gallic acid Internally it was used first by Prof C Colosanti of the Unive Rc nd U Dutto, Assistant of the Ph In Rome, who employed it in diarrhea, as well as in a number of cases of dysentery and typhoid fever (*La Reforma Medica*, 1891, Nov 30) Although these investigators reported very favorably on the efficacy of the remedy, the internal employment of bismuth subgallate has not become so extended or general as its virtues would appear to bespeak for it Perlmutter recently published a paper in the *Münchener Med Wochenschrift* on its employment in gastric ulcer and diarrhea, his observations being made on an extended series of cases and being inspired by Professor Moritz, who recommended it to his notice In diarrhea of phthisical subjects and in acute and chronic enteritis, he found it most valuable, all cases of this kind benefiting by its use, and the result being by no means only of a transient character The bismuth subgallate was given in doses of from 8 to 30 grains, in water, twice daily It is non-poisonous and produces no by-effects except a tendency toward constipation, which, however, can be readily combated by means of glycerin enemata The stools will be dark, and care must be taken not to mistake them for those colored by blood A Flint (*New York Medical Journal*, 1893, No 776) used bismuth subgallate in fermentative dyspepsia, in doses of 5 grains after meals

The writer's results agree perfectly with those of Perlmutter He has found it an excellent remedy in phthisical diarrhea, and in acute serous diarrhea of an inflammatory nature In the former cases he administers 15-grain doses three times a day, in cachets, followed by a good swallow of water In the acute diarrheas the same quantity is given every two hours until its effects become manifest, when the remedy is discontinued As a rule it does its work in a few hours, and rarely are more than three doses required In cases of severe pain or tenesmus, the writer gives with the bismuth subgallate 1 or 1½ grain of powdered opium Bismuth subgallate is undoubtedly a powerful intestinal siccative, in consequence of which it should not be administered, in acute cases, after it has reduced the frequency of the movements and altered their consistence, its action will continue for some hours after the discontinuance of the medication As a disinfectant in infectious diarrhea it is inferior to many other remedies, but as a simple astringent in phthisical diarrhea and in acute gastro-intestinal disturbances attended with profuse serous discharges the writer has found bismuth subgallate one of the best remedies at the disposal of the physician

Phenol-bismuth was the next bismuth compound brought forward, or, more properly, bismuth carbolate, of the formula $Bi(OH)_2 C_6H_5O$ It is a whitish or gray, neutral, almost odorless and tasteless, insoluble powder, containing 80 per cent of bismuth oxid and 20 per cent of phenol It was introduced by M F A Jasenski, of Professor Nencki's laboratory at the St Petersburg Institute for Experimental Medicine, who found (*Archives des Sciences Biologiques*, ii, No 2), that it is slowly decomposed by the gastric juice into phenol and bismuth oxid, the larger portion, however, which has not sufficient time to be decomposed in the stomach, passes into the intestines, where the conditions are more favorable for its complete decomposition (especially in the presence of the pancreatic juice) In spite of the well-known toxic property of phenol, phenol-bismuth did not have the least injurious effect, although administered for three weeks in daily doses of 75 grains In acute proctitis, enemas of 30 grains in two fluid ounces of water, once daily brought about a cure in two days In a number of cases of chronic intestinal catarrh phenol-bismuth had a beneficial effect Prof A W Wilcox reports (*Post-Graduate*, May, 1895) that in the various forms of chronic gastritis characterized by pyrosis, pica or boulimia, bismuth carbolate is an excellent remedy, and in gastric cancer, while bismuth subnitrate may mechanically protect the ulcerated surface, phenol-bismuth will diminish the accompanying fermentation and decomposition

The writer has obtained good results from bismuth carbolate in fermentative conditions of the gastro-intestinal tract accompanied with diarrhea, and in chronic gastro-intestinal catarrh, but he does not regard the remedy as in any manner superior to the older remedies, such as bismuth salicylate, betol and benzonaphthol The dose is 15 grains several times a day, in cachets, followed by a draught of liquid

Bismuth naphtholate was the next claimant for favor, also known as "orphol" and naphthol-bismuth This has the formula $2[Bi(C_{10}H_7O)_3]+Bi_2O_3$, and occurs as a neutral, brownish, almost odorless and well-nigh tasteless powder when recently made, and consisting of 80 per cent of bismuth oxid in chemic combination with beta naphthol It is insoluble in the ordinary solvents, and with age it is prone to darken and develop the odor and taste of naphthol It is partly decomposed in the stomach, the major portion, however, passes unchanged into the intestines, where the secretions furnish the conditions necessary for its complete dissociation Some of the naphthol is eliminated with the urine, while the greater portion of it is eliminated with the feces, the bismuth oxid being excreted with the stools, as is the case with the other bismuth compounds The first clinical reports on bismuth naphtholate are by Schubenke, Blackstein and Petkewitsch, and appeared in *Vratch*, 1892, Nos 41 and 51 They used the remedy in cases of ordinary bacillary diarrhea and of choleraic diarrhea, in daily doses of 15 to 30 grains, with good results Then came M F A Jasenski and Professor Von Nencki of St Petersburg (*Archives des Sciences Biologiques*, ii, No 2) They employed the remedy in daily doses of from 45 to 60 grains, in a number of cases of chronic intestinal catarrh and in diarrhea accompanying cirrhosis of the liver The results obtained are designated as better than those obtained with the older preparations of bismuth Prof Ferdinand Hueppe of the German University of Prague characterizes (*Berliner Klin Woch*, 1893, No 7) bismuth naphtholate as a most powerful yet non-toxic antiseptic Among other foreign physicians who have employed bismuth naphtholate with good effect should be mentioned Edmund Chaumier of Touraine, Tours, France, who reported his experience at the Congress for Internal Medicine, held at Bordeaux, August, 1895 The first American physician reporting on the use of this new bismuth salt is Prof R W Wilcox, who read a paper before the Clinical Society of the New York Post-Graduate Medical School and Hospital, Dec 15, 1894 He related the results he had obtained in some one hundred cases He believes that better results have been obtained, and in a shorter period of time, than could have been expected with the inorganic bismuth compounds In typhoid fever, he says, there is probably no remedy so generally useful as an intestinal antiseptic as bismuth naphtholate, provided it is used in the early stage of the disease, and in phthisical diarrhea a rapid increase in the dose to 60 grains or even 120 grains per day, has given brilliant results Louis Fischer (*Medical Record*, July 13, 1896) gives decided preference to bismuth naphtholate in summer complaint in children To a child one year old 5 grains may be given every two, three or four hours, with a little boiled (sterilized) water, and preferably when the stomach is quite free from food If there is persistent vomiting he gives the remedy per rectum in suppositories, double the dose per mouth being employed for each Hugo Engel of Philadelphia has used (*New York Medical Journal*, March 30, 1895) bismuth naphtholate in a considerable number of cases of fermentation and bacterial diarrhea arising from the presence of infectious material in the alimentary canal, and considers it a most reliable intestinal disinfectant and astringent in these instances

The writer has employed bismuth naphtholate in various disorders of the gastro-intestinal tract of bacterial origin Very good results were obtained in chronic catarrhal gastritis characterized by sour stomach, eructations, pyrosis and regurgitations of acid fluids Five grain doses were administered three times a day in capsules or with syrup, and followed by a draught of hot water Ordinary fermentative diarrheas were also promptly relieved by doses of from 5 to 8 grains every four hours As already stated, bismuth naphtholate with age assumes a dark-brown color and develops a naphthol odor and taste, referable to partial decomposition, and in this condition it is apt to be rejected by the stomach A preparation of a pronounced naphthol odor and taste should not be employed

Tribromphenol-bismuth, known chemically also as bismuth tribromphenate or bismuth tribromcarbolate, and styled by the manufacturer "xeroform," was the next introduction in the field of intestinal astringents and antiseptics It has the formula $(C_6H_2Br_3O)_2Bi$-$OH+Bi_2O_3$, and it occurs as a yellow or greenish-yellow, nearly odorless, neutral powder, of a faintly sweetish taste, containing 50 per cent each of tribromphenol and of bismuth oxid In the stomach it undergoes but little change, while in the intestinal canal it is gradually decomposed into tribromphenol, which possesses great disinfectant power, and bismuth oxid, which unites largely with the ptomains or their toxins, forming with them insoluble substances A small portion of the tribromphenol is eliminated with the urine, and the bismuth oxid is removed with the feces as sulphide Tribromphenol-bismuth was first recommended by Prof F Hueppe of the German University at Prague as a remedy in Asiatic cholera (*Berliner Klin Woch*, 1893, No 7) He employed doses of 8 grains every two hours, after an initial dose of 15 grains, two to four doses of 8 grains being given at night Hueppe contends that with this treatment the diarrhea improves by the removal of its cause, that is, the products of the comma bacillus are in some way neutralized by the remedy If we accept his statements, tribromphenol-bismuth is an excellent and non-toxic disinfectant in cholera Prof R W Wilcox read a paper on the preparations of bismuth, before the Clinical Society of the New York Post-Graduate Medical School and Hospital on Dec 15, 1894 The author expressed the opinion that tribromphenol bismuth possesses marked antiseptic power, as well as the soothing effect common to bismuth compounds, and advocated its use in fermentative diarrheas L Rynders of the Medical Faculty of Nancy, concludes, from his investigations of xeroform, that this is an excellent gastro intestinal disinfectant, and calls special attention to its deodorizing power on the stools of the typhoid patients (*Aerztliche Rundschau*, vii, p 694), and Bouchard confirms this opinion fully (*Wiener Med Blatter*, 1897, p 807)

The writer can commend tribromphenol-bismuth as an antizymotic and disinfectant in gastro-intestinal fermentation and in typhoid diarrhea, in the latter cases it exerts a decided deodorizing effect on the stools Toxic effects from ordinary medicinal doses are not likely to be observed, but the remedy often produces nausea and eructations if administered in wafers, powders, or capsules It is, therefore, best given in an acacia emulsion As regards dosage, in simple fermentative conditions, 8 grains every four hours suffice, but where pronounced disinfection of the intestinal tract is indicated, it is advisable to give an initial dose of 15 grains and follow with three or four doses of 8 grains at two-hour intervals and then to continue this dose, administered every four hours, until the desired effect is produced From 30 to 45 grains a day are ordinarily sufficient for a thorough asepsis of the intestinal canal in an adult

Bismuth phosphate, soluble, is another bismuth compound of recent introduction It contains 20 per cent of bismuth oxid, and is soluble in about three parts water G Leiser, O Doerffler and C Soehle (*Deutsche Aerzte-Zeitung*, 1896, No 3) employed this remedy in acute diarrheas, intestinal tuberculosis, and typhoid fever of adults, as well as in choleraic diarrheas of children In the latter, the following formula was resorted to

Bismuth phos , soluble	gm 1 5 to 2	gr 23 to 30
Distilled water	gm 90	fl℥ 3
Syrup poppies	gm 100	fl℥ 3½

Teaspoonful every half hour or hour

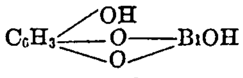
In acute diarrhea of adults the following mixture is prescribed

Bismuth phos , soluble	gm 3 to 4	gr 45 to 60
Distilled water	gm 180	fl℥ 6
Syrup fennel	gm 200	fl℥ 7

Hourly, half to one tablespoonful

No further clinical reports than the preceding are extant

Bismuth pyrogallate—pyrogallol-bismuth or "helcosol"—will be dismissed with a brief description of its physical properties, as it does not appear to have been tested clinically as yet It has the composition shown by the formula



$$C_6H_3\begin{cases}OH\\O\text{—}BiOH\\O\end{cases}$$

It occurs as a greenish-brown, amorphous, odorless, tasteless powder, insoluble in water or alcohol, and but sparingly soluble in 0 3 per cent solution of hydrochloric acid Vittorio's physiologic experiments (*Pharmaceutische Zeitung*, 1894, p 639) seem to prove that the remedy is non-poisonous, even when ingested in large doses, and that it appears to be indicated specially in infectious intestinal diseases

Bismal—designated chemically as bismuth methylenedigallate — was the next bismuth compound brought forward It has the formula $4(C\ H\ O\ )+3Bi(OH)_3$, and it occurs as a grayish, voluminous powder, soluble in water or acidulated solutions Clinical reports on bismal are as yet quite sparse F von Oefele recommends it (E Merck's "Bericht," 1896, p 123) in very chronic diarrheas where opiates are but little or not at all effective—in such as accompany certain gynecologic and tuberculous affections He administers from 3 to 8 grains in cachets, three times daily or every three hours, according to the urgency of the case D de Buck and P Vanderlinden (*Belgique Médicale*, 1896, No 36) also successfully used bismal in tuberculous enteritis They gave 15 grains from three to four times a day, in oatmeal gruel

Eudoxine was the next claimant to favor It is the bismuth salt of tetraiodophenolphtalein ("nosophen") The latter is obtained by the action of iodin on solution of phenolphtalein It has acid properties, combining with alkalies or oxids of the metals to form salts Of these, two have thus far been prepared for medical use the sodium compound, known in the trade as "antinosine," a readily soluble surgical antiseptic, and the bismuth salt, eudoxine, which is the intestinal disinfectant and astringent under consideration here Eudoxine occurs as a reddish brown, odorless powder, insoluble in the ordinary solvents and undergoing decomposition into an alkali salt of nosophen and bismuth oxid on contact with alkalies It contains approximately 53 per cent of iodin and 14 5 per cent of bismuth On internal administration eudoxine passes the stomach unchanged (unless the contents are alkaline), while in the intestines, where the natural faint alkalinity is enormously increased in morbid states, it is decomposed, as above indicated, into bismuth oxid and sodium tetraiodophenolphtaleinate The latter passes through the intestinal coats by way of the absorbents, and, according to Binz and Zuntz (*Fortschritte der Medicin*, 1896), it is again secreted into the intestinal lumen, and thus exerts a continuous disinfectant action The first clinical test of eudoxine was made by Ph Rosenheim, of Prof Senator's clinic, Berlin (*Berliner Klin Woch*, 1895, No 30) He used it in a few cases of chronic dyspepsia and of summer diarrhea of children, and in 24 cases of enterocolitis in adults Of these latter, 7 were tuberculous, and in them no result was attained by the eudoxine, 17 were of simple catarrh, of which 5 remained unchanged, 3 improved, and 9 almost entirely recovered The ordinary dosage was from 5 to 8 grains, from three to five times a day The next clinical report was by Anton Lieven, and was made at the Fourteenth Congress for Internal Medicine, held at Wiesbaden, April 8–11, 1896, and all the remaining reports discoverable by the writer are American physicians Prof R W Wilcox of New York (*Medical News*, 1897, July 31) employed eudoxine in 35 cases Fourteen suffered from chronic intestinal catarrh, of these, six presented coincident hepatic and cardiac lesions Naturally, the latter class would be benefited by drugs which would influence the liver and heart, but Dr Wilcox is confident that the benefit was more rapidly obtained than it would have been without the use of the bismuth preparation Three patients presented intestinal fermentation, with discharges of muco-pus, considerable pain, and foul smelling stools, these experienced relief, although one required treatment for several months Four patients suffered from simple intestinal fermentation, these were permanently relieved although in one instance, nearly five months elapsed before treatment could be suspended Two women presented exfoliative membranous enteritis, both were put to bed, and received high intestinal irrigations with salol, with a carefully regulated diet and general supervision of all matters which are conducive to restoration of health In addition, the drug was used in maximum doses Both patients passed some months without the passage of shreds or membranes Nine patients presented symptoms of both gastric and intestinal catarrh They all improved, but not so rapidly as could have been wished until resorcin in 5-grain doses was given before meals The final result was satisfactory Two patients suffered from acute catarrhal duodenitis, with cutaneous itching, absorption jaundice, tender liver, and clay-colored and offensive stools Both were relieved, so far as their intestinal symptoms were concerned, although calomel in small doses (1/10 grain) at hourly intervals was given at the same time Both presented well-marked conditions, and obtained relief from the intestinal decomposition with more than usual rapidity The drug was not irritant, although Dr Wilcox believes that the effect of the iodin content of the drug upon the glands of the intestines is to render the stools less consistent Prof N S Davis, Jr of Chicago, reports (*Medical Standard*, September 1897) having used eudoxine in a large number of cases In many mild cases of chronic enteritis he has been able to almost completely check intestinal fermentation with it in a few days, and it seemed to accomplish this more promptly than any other remedy except naphthol, over which it has the advantage of being agreeable to take and harmless In mild cases he gives from 3 to 5 grains four times daily, if intestinal fermentation is considerable, he administers these doses every two or three hours In gastritis the remedy has done no perceptible good, but in enteritis, whether associated with inflammation of the stomach or not, it has uniformly seemed to be of benefit, except when intestinal fermentation was unusually great The only other reports extant are by E P Herscher of Denver, who speaks well of eudoxine in chronic intestinal inflammation (*Western Medical and Surgical Gazette*, 1898, No 4), and by Schön-Ladniewski of Lemberg (*Weiner Med Presse*, 1897, No 45)

The writer has found eudoxine serviceable in chronic gastro enteritis and entero-colitis, where it manifests a mild and continuous disinfectant and astringent action In acute infectious diarrheas, and in cases of extreme intestinal fermentation, it is not likely to be of benefit, and is here calculated to prove vastly inferior to stronger disinfectants and antizymotics, such as benzonaphthol, for instance I have never observed untoward effects from its use As regards dosage, to adults from 5 to 10 grains may be given, to children from five to ten years of age, from 1½ to 3 grains, to babes of four months, 3/3 grains, to nurslings of two months 1/3 grain, and to those still younger, 1/6 grain

Benzonaphthol—Napththol benzoate, $C_6H_5COO-C_{10}H_7$ was introduced by Yvon and Berlioz (*Semaine Médicale*, 1891, p 91) to supersede betol (naphthol salicylate), over which it was claimed to have the advantage of being less irritating and not as toxic Benzonapthol occurs as a white, odorless, tasteless, insoluble powder Its therapeutic employment depends chiefly on its content of naphthol In the intestines it is decomposed into benzoic acid and naphthol, the former being eliminated with the urine as alkaline hippurates, the naphthol as naphthol sulphuric acid Prof C A Ewald (*Berliner Klin*

Woch, 1893, No 35) has found benzōnapthol of the greatest service in various dyspeptic disturbances, flatulence and chronic meteorism from intestinal atony, particularly when associated with bismuth subnitrate and resorcin He gives 8 grains every two hours However, the remedy is not absolutely infallible, furthermore, in a few exceptional cases of Ewald's, intestinal colic and diarrhea supervened, but promptly disappeared on discontinuing the medication

M Bernitt (*Wiener Med Presse*, 1892, No 51), Bruck (*Pester Med Presse*, 1892, No 46), and Zinnis (*Deutsche Med Woch*, 1892, No 30) recommend benzonaphthol in infectious gastro-intestinal diseases of children and babes, while Kuhn of Giessen (*Deutsche Med Woch*, 1893, No 19) denies it all virtues in these affections

The writer has found benzonaphthol an efficacious antizymotic in conditions characterized by inordinate fermentation, whether functional or inflammatory in nature The dose for adults is from 8 to 10 grains every two hours, or about 80 grains a day, administered best in cachets, for children up to one year of age, from 1/2 to 2 grains every few hours, from one to three years, five times daily, 3 grains, from four to seven years, 24 grains per day, from eight to fourteen years, 30 grains daily, with an equal part of sugar or a trace of saccharin In chronic cases full action sets in only after four or five days, its astringent properties are not very pronounced

I believe I have alluded to all the antidiarrheal remedies introduced during the last few years Should any member desire information regarding any other intestinal remedies, the writer of this paper shall deem it a pleasure to supply the desired data so far as lies in his power

THE MEDICINAL TREATMENT OF SOME DIGESTIVE DISEASES

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual meeting of the American Medical Association held at Denver Colo, June 7-10 1898

BY A L BENEDICT, A M, M D,
PROFESSOR OF PHYSIOLOGY AND DIGESTIVE DISEASES DENTAL DEPARTMENT UNIVERSITY OF BUFFALO
BUFFALO N Y

There has always been a tendency, both within and without the medical profession, to scoff at drugs The tremendous development of certain scientific and mechanical departments of the healing art, within the last two decades has, by contrast, placed the homely skill of using medicines in the background Teachers and students of medicine have alike neglected the old fashioned details of therapeutics, therapeutic nihilists have arisen who have sought to discredit the value of drugs and, naturally enough, the preconceived notion that ponderable therapeutic agents have little use, has made it possible for those who hold such a view to demonstrate their belief from their own experience The writer is sufficient of an old fogy to hold that if the regular profession would devote to the physiologic and therapeutic study of drugs the same amount of pains that the homeopaths bestow upon what we believe to be false theories, a great advance would follow, and internal medicine would be correspondingly dignified

Disease is, in the main, a chemic disturbance, though often of so recondite a nature that we are forced to employ some such non-committal term as "vital" and to abandon all thought of cure through the agency of an ordinary chemic reaction Even in this latter kind of disturbances, we often find a well-established antagonism between disease and drug, which can not be explained but to which we allude under the term "selective affinity" In general, it may be said that a priori, there is just as much rationality in expecting relief from the action of a chemical circulating in the blood as from the effervescence of a briny bath, or the hanging of a nervous case by the chin and occiput till cured, or the kneading of dermal and subcutaneous tissues, or from reducing a human being to a vegetative state, all of which are methods of therapeutics in good repute and of great value

Digestive disturbances afford an especially favorable field for the application of drugs, 1, because they are usually more or less chronic and yet not sufficiently urgent to induce the patient to make the sacrifice of time and business interests demanded by hygienic therapeutics, 2, because an exact diagnosis, at least of the immediate physiologic failure, is usually possible, though requiring skill and special methods of examination, 3, because these abnormalities are, to a far greater degree than those of other organs, either chemic or vital in so simple a way as to be amenable to drugs 4, because surgical treatment is applicable to but few cases and, to these, with a grave prognosis, 5, because really valuable means of local therapeutics have been greatly abused, as to technique and frequency of employment

For practical purposes the majority of gastric disturbances may be considered functional The writer's personal opinion is that they are much more frequently dependent on organic change than is usually supposed, but as death seldom occurs, and as postmortem changes can very rarely be prevented or anticipated, for obvious sentimental if not better reasons, we know very little about the actual state of the gastric mucosa in dyspepsia Even the microscopic examination of particles of epithelium obtained by siphonage or spontaneous vomiting, is not reliable, since there is normally a shedding of more or less degenerated epithelium Probably 70 per cent of gastric diseases, taking them as they occur, are essentially atonic dyspepsias, characterized by deficiency of hydrochloric acid and by sluggish motor action The immediate relief of the former condition is ideally fulfilled by the administration of the same acid, while without obvious catarrhal involvement, local treatment is not indicated As to the motor function, probably nine out of ten physicians who were thoroughly impartial, that is to say inexperienced, would declare that the ideal treatment was the intraventral use of faradism But, considering carefully the various experimental studies as to the action of electricity on the muscle of the stomach, we must conclude that, while it is not absolutely impossible to note a contraction during the time that the battery is in use, there is no evidence that the faradism stimulates the gastric muscle to contract when subjected to this method of treatment On the other hand, we have a drug, strychnin, which most certainly does stimulate smooth muscle, whether of the stomach or elsewhere in the body, and whether we depend upon physiologic experiments or clinical experience Such cases—and others—might be thought suitable for the employment of hygiene But we find that ordinary gymnastic exercises do not produce much improvement, that the fresh air of the country or sea-side is overbalanced by the difficulty of finding proper food in either the typic farmhouse or hotel Heaven forbid that we should expose such patients to the bacterial and mental infection of a sanitarium or that we should initiate them into the mysteries of invalidism by prescribing massage and rest-cure They may be cured with great éclat by lavage, but they simply do not need to subject themselves to the discomfort and expense of this method, unless the case is extreme Neither are they fit subjects for the believer in the elaborate simplicity of dietetics Some few atrocities of modern cookery may be forbidden but, as a rule, the stomach needs the stimulation of varied and appetizing food, and the more such patients are dieted the more they have to be, the gastric power failing concomitantly with the diminution of the task set before it Not rarely we find patients who are relieved by hydrochloric acid and strychnin but who do not regain the power to digest without this assistance Then hygiene, change of air and scene, rest and recreation, come into play, but they must follow, not precede, medication

In the rather rare cases in which the stomach produces too much acid, avoidance of chlorids, of stimulating food and of irritating circumstances of all kinds, are the prime indications If treatment, except in a negative sense, is needed, alkalies and secretory depressants are efficient Rest is undoubtedly the ultimate need of most such patients, though there are a few who are lithemic, and who need some offset to idleness and high living Very rarely indeed is the rest-cure indicated, there being a great difference between *rest* and *rest cure*

As to ferments, the following general statements may be made 1, there is no information or reasonable supposition that a ferment of the digestive glands is ever produced in excess, 2, the failure of a ferment occurs only in the most serious organic disturbances—though not necessarily locally organic, thus, fever is often attended with failure of ferments The salivary ferment is particularly resistant to disease, though not of very great importance in health, 3, the administration of ferments should never be resorted to without first demonstrating their absence, 4, after proving that a ferment really is deficient—something that occurs in scarcely 1 per cent of cases—we must ask whether the stomach and intestine are in a condition to digest on the mere supplying of the ferment, or whether predigestion, rectal nutrition, etc, are not indicated As a rule, the body which lacks ferments lacks the power of using them if artificially supplied

Gastric catarrh, ulcer and cancer, for many therapeutic considerations, duplicate the indications of purely functional dyspepsia, if such a thing exists The lack or excess of acid, the need of a motor tonic, the indication for an antiseptic or anesthetic, must be worked out, case by case, without attempting to rely on a general rule While a stomach which is badly dilated and diseased so that food actually ferments and putrefies can be cleansed only by repeated lavage, there are efficient internal antiseptics which are all that are needed for the milder cases, and which usually are indicated in addition to lavage, in the severer conditions All things considered, oil of peppermint is the best of these, but oil of wintergreen may be used if there is a joint indication—no pun is intended—for the employment of a salicylate For more gradual antiseptic action, when we must consider the bowel as well as the stomach, salacetol is of the highest rank The writer's experience is not so favorable for the benzo compounds though these are also antiseptic Hydrogen peroxid is especially valuable when there is muco purulent matter present

Surgery suggests itself mainly in the relief of gastric cancer and ulcer With the former, the theoretic indication for surgery is balanced by the difficulty of making a diagnosis in time and by the grave prognosis, so far as the *operation itself* is concerned, so that at present the average case of cancer will continue to receive mainly medical attention Although the result is inevitably fatal, it must not be forgotten that the duty of the physician is all the more urgent to maintain *comfort, and that the ordinary gastric cancer* does not occasion the sharp pain that is too frequently connected with malignant disease, hence there is much room for rational treatment in improving digestive deficiencies, in maintaining gastric motility, in keeping the chyme aseptic and even in obtaining healing of malignant ulcerations Morphin is by no means a drug to be freely used Gastric ulcer, superficially considered, might be thought to indicate ligation of the bleeding part, but medical and surgical opinion is very nearly unanimous that operation is not feasible The local use of styptics is plainly contraindicated, first, because it is impossible to get them to the site of hemorrhage in sufficient quantity and sufficient concentration, secondly, because they are all irritants, and tend to cause retching, which aggravates the primary trouble The real indications are two—absolute quiet obtained by morphin, and vascular constriction by ergot Both should be given hypodermically To the best of the writer's knowledge, there is no satisfactory preparation of ergot for such use, all being irritating and some of the so-called ergotins being of unfixed dosage On the whole, the official fluid extract is about as good as the more expensive preparations Few physicians realize that many of the unpleasant symptoms and part of the actual danger of gastric ulcer are due to absorption of decomposed blood Indican is found in the urine in enormous amount and there is great need of intestinal asepsis Still, for the first twenty-four hours at least, the need of quiet is so urgent as to forbid cathartics, enemata, or even *intestinal antiseptics* A little ice is usually given, simply to keep the patient from being too restless, but even this is to be avoided as far as possible After a day or two, salacetol or bismuth subgallate may be given and, after the bowels have been freed from blood, it is well to give bismuth systematically, rather as an astringent dressing than as an antiseptic The writer's preference is for a 10 per cent emulsion of bismuth hydrate in water, or pure liquid petrolatum, if the patient shows no distaste for the mineral oil

In gastric catarrh, with or without dilatation, bismuth subgallate is an excellent and efficient remedy, though by no means able to supplant lavage and inflation with menthol or similar sprays In any condition in which the gastric mucosa is involved, we must make a sharp distinction between the needs of the stomach itself and the needs of the digestive process Usually, there exists quite a definite opposition between these two indications, the more or less alkaline and astringent application which is generally *needed for the gastric wall interfering with digestion*, while the hydrochloric acid and secretory and motor stimulants required to assist digestion are somewhat irritant to the diseased mucosa In cases that are absolutely or practically functional, we naturally pay attention only to the digestive deficiencies, in severe organic diseases, such as acute catarrh, ulcer and some manifestations of cancer and chronic catarrh, gastric digestion must be discontinued entirely for at least a few days, the body being nourished by the bowel and skin while the stomach is being medicated A large number of cases fall between these two extremes and, as a number of favorite ready-made tablets and liquid mixtures show, many physicians simply stir together the various drugs indicated and administer them all at once, letting their diverse activities battle for the supremacy In such cases, the rational treatment consists in doing one thing at a time Give such foods as may be digested in, say, three hours, in other words, rather plain but still appetizing and ordinary articles of food Administer such digestive aids as shall insure digestion and emptying of the stomach in about this time Then, every morning and afternoon, a period of two or three hours is at our disposal for medicating the gastric wall, while a drug administered at bed-time has a much longer period of possible action The writer would confess that his conception of a drug acting on the stomach and bowel itself is pretty nearly limited to bismuth The various vegetable astringents lack the property of a powder dressing, silver, copper and zinc are too active for more than temporary use, and each, moreover, possesses special objectionable features Cerium oxalate has no obvious advantage over bismuth, while, in most of the cases in which one or the other must be used, there is altogether too much oxalic acid formation in the system The main point in administering bismuth is to give enough of it With the possible exception of some of the newer antiseptic compounds, the minimum dose should be half a gram, and twice or three times this amount should usually be given Yet, within a few days, a cautious druggist has telephoned the writer in regard to overdose in the case of a prescription calling for a gram of the subgallate, three times a day

For the long reach of bowel between the accessible portions of the alimentary canal, the same general principles of medication apply as to the stomach It is of the greatest importance to be sure that the intestinal disturbance is not the final breaking down of the power to perform vicariously the duties of the stomach Many stomachs habitually shirk digestion, and the owner is unaware of the suspension of function so long as the gastric motor power is sufficient to pass the chyme on to the duodenum Next, by high enemata, we must keep the lower bowel clean and healthy Finally, we must administer the slowly soluble antiseptics, occasionally ferments inclosed in stomach-proof coatings, and usually the astringent bismuth, preferably now in pure petrolatum Juggling with cathartics and constipating drugs is not therapeutics, although it may be an inevitable makeshift

Although in scolecitis, surgery affords the safest and most thorough treatment, there are certainly many mild cases which recover under either constipating medication with opium, or laxative treatment with salines or belladonna, with or without intestinal antisepsis and hydrotherapy If we could be sure that free drainage existed from the mouth of the appendix and that gangrene and virulent ulceration could be excluded, medical treatment of even acute cases might be justifiable But, at present, the only cases in which operation should not be insisted upon, are mild and more or less chronic ones, the patient being so situated that surgical aid may be called almost at a moment's notice If we carefully consider the history of scolecitis cases, we must conclude that not grape seeds, nor other foreign bodies, not constipation, not necessarily catarrh of the bowel, not taking cold, not even anatomic peculiarities as to meso-, blood-vessels, and lymphoid tissue, are the essential causes The real cause in the writer's belief, is unusual virulence of intestinal bacteria, marked by prolonged intestinal indigestion and fermentation Thus, there is a rational field for the use of antiseptics, drugs to regulate the proper discharge from the bowels, including water, and, in addition, some of the slowly soluble compounds of iodin as resorptives

In our appreciation of the seriousness of scolecitis and the danger of too long delay of operation, we have gone rather too far in abandoning the old-fashioned conception of typhlitis There most certainly do exist cases of catarrh and atony, especially of the head of the colon, though not absolutely limited by an arbitrary anatomic division Here we find the sausage shaped fecal tumor just as truly as did our predecessors, and, in the absence of leucocystosis, of a septic temperature and pulse, we have as plainly as ever an indication for medical treatment, including salines, antiseptics and, later, such means as will check the tendency to catarrh and prevent an atonic yielding of the bowel

---

THE TREATMENT OF HEART DISEASE BY SALINE BATHS AND RESISTED MOVEMENTS—SCHOTT METHOD

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY CHARLES LYMAN GREENE, M D
CLINICAL PROFESSOR OF MEDICINE AND PHYSICAL DIAGNOSIS, MEDICAL DEPARTMENT OF THE UNIVERSITY OF MINNESOTA VISITING PHYSICIAN TO THE CITY AND COUNTY HOSPITAL AND
ST PAUL FREE DISPENSARY
ST PAUL MINN

The value of a therapeutic agent or method can not be measured by the volume of its literature nor yet by the enthusiasm of its advocates, and no doubt too great a measure of faith in the testimony of false witnesses has bred in us that skepticism which, however admirable as a mental attitude in scientific work, may nevertheless, if too greatly expanded, become a serious stumbling-block in the path of medical progress We are right in insisting upon something more than dogmatic assertion or the voice of authority in the determination of therapeutic values, we may justly demand the right to withhold judgment, ask for substantial proofs and thoroughly sift our evidence, but behind all this there must be a sincere and earnest desire, not alone to detect error, but also to know the truth, and the ultimate test must after all be derived from personal experience and the repetition of such experiences

If a new procedure is rational, if the evidence in its favor seems fairly good, and if it promises more than the old, we are in duty bound to give our patients the benefit of the trial The world has not moved very greatly in this direction in the last 200 years We may now read with astonishment the vituperative paragraphs which proved with a most imposing show of logic and a vast amount of physiologic and anatomic data that Harvey's great theory was the acme of absurdity, but we must also admit with some shame that nearly fifty years of this nineteenth century were required for the establishment of typhoid fever as a distinct clinical and pathologic entity. Upon the other hand, we wonder at our simplicity in accepting scores of therapeutic novelties, only to find them worthless and not always harmless. Curiously enough, too, that old stumbling-block—the blind worship of great names—has in the last two decades been stimulated by bacteriologic and pathologic discovery only to be discredited later by some unsatisfactory and hazardous therapeutic methods derived from the same sources. We have learned, for a little time at least, that even the greatest investigators must be allowed a little leeway when they enter the field of clinical diagnosis and therapeutics, and that important and valuable discoveries may lack the endorsement of a great name. During the past forty years there have come from time to time communications from certain medical men in the little town of Nauheim, Germany, and these claimed that remarkable results might be obtained in chronic heart disease by the proper use of gymnastics and baths. Beneke, Groedel, and August and Theodor Schott in admirable articles, stated again and again the facts as we know them now. Their treatment was rational, their results extraordinary, yet only a casual notice was granted them and their work. Suddenly, after four decades of neglect, a few men in this country and in England began to write of the treatment and publish their own experience, then followed a flood of literature and Nauheim, formerly an unimportant station, was visited by one hundred thousand patients in a single year. It will be seen then that the so-called Schott method is not new, but that after forty years of sheer neglect it has received a partial recognition and been placed upon trial by our profession.

The greater part of its literature, strange to say, is to be found in British journals, the most conservative in the world. It is for the most part very recent. As late as 1894, when the writer first used the treatment, there was but little in the English language—or indeed in any language—and curiously enough, American physicians, the most progressive in the world, have been almost as little concerned with it as the French, whose indifference has at least the excuse of racial antipathy. Heineman, Babcock, Camac and the writer have been the only American clinicians who have reported upon it. In England the flood of medical controversy was initiated by Bezley Thorne's enthusiastic advocacy of the treatment, and as a result the method was brought prominently before the most conservative element of our profession. The result has been remarkable. The favorable reports of several of the most eminent English clinicians, who visited Nauheim and personally investigated the effect of the baths and movements, the fact that the special commission of the *Lancet* also endorsed the treatment, and the confirmatory case reports from many sources combined to place it before the profession of the British Isles in a very favorable light. Such criticism as has developed has been, with one or two exceptions, of the honest and helpful variety, which seeks to correct hasty conclusions, modify extravagant statements and establish a correct theory as a basis for therapeutic application. For here, as elsewhere, there are extremists, and men who will tell us to a millimeter the shrinkage of a dilated heart after a bath, and who court disaster by an undiscriminating advocacy of a powerful agent, are opposed by men who deny the evidence of their own senses—and still more emphatically that of other men's senses—and condemn the treatment without a fair trial. There is a middle ground. Four years' experience with the Schott method in public and private practice has convinced the writer that it is a method which is well-nigh indispensable to the efficient treatment of chronic heart disease, provided always that it be applied intelligently and only in appropriate instances. Indiscriminate use of so potent a remedy means certain disappointment and positive injury in many cases.

The Schott method ought rather to be called the Method of Treating Chronic Heart Disease by Baths and Resisted Movements, the brothers August and Theodore Schott having been instrumental in securing the wider acceptance of the therapeutic method, and in combining the baths and Swedish movements to make a rational system, but having no genuine claim to original discovery. To Beneke, who wrote first in 1859, and to Saetherburg, the originator of the resisted movements, must be granted a large portion of the credit, hence no one man's name should be given to the method.

DESCRIPTION OF METHOD

What is the so-called Schott Method? It may be stated briefly as consisting of the systematic use of saline baths of definite strength and temperature, and the coincident or alternative employment of a certain series of resisted movements. The treatment originated in Nauheim, Germany, where the natural springs are strongly saline and heavily charged with carbonic acid gas, their varying temperature and strength making them admirably adapted to therapeutic use. The chief of a multitude of chemical constituents of these baths are sodium chlorid (1 to 3 per cent.), calcium chlorid (1 to 3 per cent.), with a considerable quantity of iron and a large amount of free carbonic acid gas. Their temperature varies from 81.7 to 95.5 degrees F. In practice the higher temperature and weaker waters are first used, the water being freed from the carbonic acid gas, a lower temperature, effervescent bath and greater strength in saline constituents being gradually attained as the treatment progresses. Baths are given daily, rarely more than three being taken consecutively, that of the third or fourth day being omitted. While the natural baths are better adapted to treatment, perfectly satisfactory results may be obtained from artificial baths made after the following formula.

Formulæ.—To 40 gallons of water (usual amount required) add sea salt, 3 to 10 pints (approximate strength 1 to 3 per cent.), calcium chlorid, pure, 11 to 15 ounces. It is important to note that this latter ingredient is not the commercial chlorid of lime, which, by giving off chlorin, would become a source of discomfort and danger. To introduce or generate carbonic acid gas we may use a soda siphon with conducting tube or the following formulæ of Bezley Thorne.

Mild—$NaHCO_3$, ½ pound, HCl (25 per cent.) ¾ pound.
Medium—$NaHCO_3$ 1 pound, HCl (25 per cent.) 1½ pounds.
Strong—$NaHCO_3$, 2 pounds, HCl (25 per cent.) 3 pounds.

The salts are first dissolved, the hydrochloric acid is then added and thoroughly distributed. The writer has found the best agent for adding the acid to be a douche bottle and tube, the acid being thus evenly distributed throughout the mixture.

Immersion.—The patient remains immersed from five to twenty minutes, the first bath being brief and the period gradually lengthened If the patient be very ill he should be carried to and from the bath and spared any exertion While in the bath he should remain absolutely quiet, breathe regularly and refrain even from speaking Upon leaving the bath he may be rolled in warm blankets to rest for at least one hour

Temperature—The temperature is at first about 93 degrees F, and may be considerably reduced after the six or eight baths have been taken and the use of carbonated baths begun, provided such reduction is considered necessary Usually, the patient's sensation is a safe guide to the regulation of temperature The bath should feel pleasantly and quite definitely warm throughout the period of immersion, and the patient should be cautioned and told to report at once any tendency to chill

The movements are very simple Swedish movement, and as recommended by Schott, comprise nineteen exercises, so planned as to bring into action every muscle group in the body These are best illustrated by plates, such as I now place in your hands[1] The movements are intended to produce without fatigue the beneficial result of exercises, and are of decided value in the treatment of almost all cases to which the baths are applicable

Before considering the effect of these baths and movements let us inquire what are the conditions which must be fulfilled by the ideal remedy for chronic heart disease They are the following *a*, the heart must be rested and strengthened and its own cell metabolism and circulation be improved, *b*, the peripheral resistance must be lessened, *c*, the general venous engorgement and failure in metabolism must be overcome That these indications are fairly met by this treatment in the larger number of heart lesions is positively proven by a study of the effect of baths or movements upon our patients as noted below

Effect of baths—1, There is a fleeting sense of oppression and dyspnea (rarely seen by the writer), 2, a feeling of exhilaration and well-being, 3, slowing of the pulse, and coincidently, a fuller and stronger beat, 4, brightening of skin, nails and mucous membrane, indicating relief of cyanosis, freer capillary circulation, 5, secondary reduction of pulse tension with maintenance of lower rate, 6, marked reduction in cardiac area, most marked primarily in right heart, but involving both lateral and vertical dimensions The effect of the movements is almost precisely similar, but as long maintained

The elaborate theory of Schott, which assumes the imbibition of saline and gaseous constituents and reflex stimulation through the skin, must, I think, be regarded as unnecessarily elaborate and very unsatisfactory It is not necessary to make a theory to fit any particular sort of a bath, for a simple and adequate explanation would seem to be found in the well-known effects of warm baths in general upon the circulation The chief effect of such baths is to free the circulation in the peripheral vessels, thus reducing the work of the heart and enabling it to receive and pass on more blood with less effort Rest and warmth after the baths prolong this effect for a considerable period Thus, venous engorgement is relieved, normal cell-metabolism re established, and the products of suboxidation are either consumed or swept away into their proper eliminative channels The stronger the bath and the more CO it contains, the more stimulating it will be and the less likely to be attended with chill during or after the bath, and the more marked and sudden its effects The flowing baths at Nauheim are almost precisely like surf baths in their effects, and are never used until late in the treatment In the movements much the same effects are produced as by the baths, through the opening of the immense drainage area embraced in the capillaries of the muscles To understand this we only need to remember that rapid or protracted contraction of a muscle hinders circulation and induces vasomotor constriction, while gradual contraction produces dilatation of the capillaries and mechanically assists the onward flow, thus favoring greatly the general circulation The initial rise in blood pressure noted in using the baths is, in the case of the movements, almost entirely lacking

Having thus briefly discussed the general methods without any attempt to cover minor details, you will perhaps permit a few deductions from a personal experience with this treatment extending over a period of four years, and embracing nearly one hundred cases Let us consider, 1, the necessity of scrupulous adherence to the exact formulæ representing the constituents of the Nauheim baths, 2, the relative value of the baths and movements, 3, the cases best adapted to treatment, 4, the cases in which the treatment has proven less useful, though harmless, 5, cases in which it is contraindicated, 6 the precautions necessary if the best results are to be obtained, 7, the actual results obtained in suitable cases

Is strict adherence to formulæ essential?—In the writer's opinion strict adherence is not essential, though the general make up of the baths should be about the same The important features are warmth and moisture, and excellent results are obtained without the use of any ingredient save the salt, which prevents chilling and acts as a cutaneous stimulant Carbonic acid acts in much the same way, but, while delightfully stimulating, is not absolutely necessary, unless the colder baths are used It is doubtful whether these cool baths may be safely used elsewhere than at the natural springs, and they are moreover entirely unnecessary in most cases It must be remembered that immersion in plain warm water will slow the pulse in precisely the same way as the regulation bath, but such baths are not advisable, because the feeling of exhilaration and well being is not marked, the effect upon the heart is less decided and less enduring, and the liability to chill is increased

Relative value of baths and movements—The effect of baths is more permanent than is that of the movements, but both should be used, the movements in the morning and the baths at night

Cases best adapted to treatment—It is admirably adapted to cases of incompensation of moderate severity where rest is not to be had, and to those severer cases in which rest and cardiac stimulants have proven useless or reached the limit of effect The particular class of cases best adapted to treatment are the mitral cases, particularly those of regurgitation, even if very advanced, and all cases of slight incompensation, in which marked arteriosclerosis and myocarditis are not present In exophthalmic goiter, cases of functional irregularity, of neurasthenia, in all cases of anemia and in chronic rheumatism it is very useful

Cases in which it has proven of l [illegible] *e*—In the writer's h [illegible] ac [illegible] wheth [illegible] regurgitation, [illegible] le [illegible] its

---

[1] Author Extreme Dilatation of the Heart due to Valvular Disease with Special Reference to Treatment by Schott Method International Clinics Vol ii 2d Series

No harm has been done, and many have improved, but the writer is not satisfied that the treatment is here of any decided value, and believes that simple rest and the resisted movements are much to be preferred

Cases in which it is contraindicated—These are aneurysm, marked arteriosclerosis, chronic myocarditis and chronic Bright's disease, yet, while baths are in these cases distinctly dangerous and harmful, the movements may be decidedly beneficial

Precautions—To obtain the best results, the tub should be large and the patient immersed to the chin if possible The baths should never be given hot, nor on the other hand, should the patient feel any chill during the bath Great pains must be taken to avoid voluntary movements during and after the bath If the circulation in the extremities be poor, brisk, light friction may be used If calcium chlorid be used it must be pure A very sick patient must invariably be watched by a skilled attendant throughout the bath If CO_2 is actively generated it is well to fan it away before placing the patient in the bath Cases of extreme incompensation are best treated at the outset by rest in bed, and the usual remedies, they will almost always show marked improvement, and when this improvement begins to flag one may begin the baths and use the exercise with slight daily increase in the resistance Allow an exceedingly gradual resumption of voluntary movement and accept no case of severe incompensation for less than six weeks of treatment

The following rules must be observed in using the movements Remember that they are intended to produce the beneficial result of exercise without fatigue, and you have the keynote of success, and can appreciate the scrupulous care necessary in using them in chronic heart cases The nicest judgment and most painstaking skill are required, and increase of the pulse-rate, pallor, or evidence of dyspnea warns is to stop at once The amount of resistance, rest ntervals, and number of movements well borne by he patient must be left to the operator's good sense Furthermore, the clothing must be loose, each movenent should be performed deliberately and smoothly, he breathing must be deliberate and regular, the esistance should be varied according to the strength of the patient and the effect produced, and no movenent should be repeated in the same limb or muscle group Thus simple and rational are the principles of this treatment

Results obtained—If proper care in the selection of cases and strict supervision be exercised, the results are really remarkable The writer has never seen such extraordinary shrinkage during the first bath as has been described by some writers (3 inches), but in an old mitral case a man must be strongly biased or a trifle weak in his physical diagnosis if he can not easily demonstrate a decided recession of the borders during the bath That this is not due simply to the somewhat deeper breathing induced by the bath, as has been asserted, may be easily demonstrated by testing the effect of similar breathing before the bath It must be remembered, however, that rest alone may produce remarkable shrinkage in a dilated heart, and it is probably wise to try rest, digitalis and strychnin for the first week or two and thus get a very gradual rather than rapid change in the conditions As before stated, we always arrive at a point where progress is slow, and then the baths are indicated While the writer believes that the effect of the baths is often overestimated, by reason of the fact that the effect of simple rest is underestimated, yet the shrinkage of the cardiac area, the improvement of the heart action, the pronounced diuresis, and the prompt removal of secondary symptoms under this rational and simple treatment are decidedly impressive and, in the writer's opinion, no treatment of dilated heart can leave the salt baths and movements out of that great therapeutic combination which includes digitalis and strychnin, baths and resisted movements, walking on the flat and hill-climbing The rational therapeutist can omit none of these from his list, yet he might find it hard to fix their relative importance If the writer were forced to discard all means but one, baths and resisted movements would be his choice as being of the broadest application But fortunately we are not thus limited, and the measure under discussion forms in any event one of the most important adjuncts to the successful treatment of heart disease

NOTES ON TYPHOID FEVER

TWO HUNDRED AND TWENTY FIVE CASES TREATED DURING AN EPIDEMIC OF THAT DISEASE

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo June 7 10 1898

BY J P BARBER, M D
MINNEAPOLIS

Typhoid fever remains a most interesting study Its pathology, which was supposed to have been settled years ago by the discovery of the bacillus of Eberth, will have to be remodeled to fit certain facts of recent research The bacteriologist, who has done so much to illuminate this disease, can not yet call his labors finished The best efforts of the therapist to evolve a treatment which will abort, or even materially modify, the course of the disease have signally failed The clinician must often confess his shortcomings in its diagnosis

An epidemic of this disease began in the city of Minneapolis in February, 1897, and was traceable directly to the water-supply Drs Westbrook and Wilson,[1] of the laboratory of the State Board of Health, isolated the bacillus typhosus from the water in April of that year Nearly every case seen during the months of March, April and May was typic and severe The spring floods, which came about the middle of May, were unusually severe and the river, from which the water supply is taken, remained comparatively high during the remainder of the summer and fall Then followed a series of most interesting cases, more than half of which were atypic The total number of cases seen by the writer from March 1, 1897, to May 1, 1898, was 225 Of this number 114 were typic and could have been easily diagnosticated clinically The remaining 111 were atypic, and many of them could not have been identified without the aid of certain laboratory tests For convenience these 111 cases are divided into three classes, as follow 1, the extremely mild, 55 cases, 2, abortive, 28 cases, 3 beginning concurrently with some other disease, 28 cases

The first class of cases is well illustrated by the following history

Class 1—C B , male, aged 32, had been feeling ill three days, headache, anorexia, lumbar pains, general muscular soreness, temperature 99 degrees F at 3 P M , tongue slightly furred with white coating, slight tenderness on deep pressure over right iliac region, diazo reaction and serum test both negative

Fourth day Temperature, 9 A M, 97 6, 3 P M, 99 degrees, other symptoms about the same, urine and blood tests both negative

Fifth day Temperature, 9 A M, 97 8, and 5 P M, 99 degrees, headache and muscular pains increased, tongue more deeply coated, bowels constipated, urine shows faint rose color with diazo reaction, serum test negative

Sixth day Temperature, 9 A M, 99, 4 P M, 99 8 degrees Distinct rose colored diazo reaction, serum test negative

Faint grouping was noted with the serum test on the eighth day, and a perfect reaction on the tenth, twelfth, fourteenth and twentieth days Slight enlargement of the spleen was noted on the tenth day The temperature vacillated between 97 6 and 99 degrees from the eighth to the eleventh days, after which it remained normal The tongue cleared off, appetite returned and the patient felt as well as usual

This class, of which the above is a good representative, presents many variations in the symptoms But, as a rule, the usual prodromata are present, with a very low fever of ten days' to two weeks' duration All have reacted to the diagnostic tests for typhoid fever

Class 2—Alice W, female, aged 13 years Had eaten inordinately of sweetmeats three days ago, has been vomiting ever since, intense headache, epigastric pain and tenderness Temperature 103, pulse 90, respiration 20, diazo reaction and serum test absent

Fourth day Temperature, 3 P M 104, respiration 20, pulse 96, vomiting ceased, tenderness over entire abdomen, diazo reaction intense, serum test negative

Fifth day Temperature 9 A M 102, 4 P M 103, headache not so severe, feels much more comfortable, no pain in epigastric region, but still tenderness on pressure over abdomen, area of splenic dullness considerably increased, no spots, serum reaction present

Seventh day Temperature 9 A M 97 5, 4 P M 99 She feels well and wants to sit up The temperature registered between 97 5 and 99 for three or four days, the tongue cleaned off, appetite returned and she felt as well as usual The serum reaction was present on the 6th, 8th, 9th, 12th and 20th days

This is a fair representative of this class of cases The outset is generally rapid, sometimes sudden with chill or, if the patient be a child, convulsion The temperature rises to 104 or 105, or even higher, for three or four days, then suddenly the disease terminates by crisis similar to that of pneumonia There is generally no cough in these cases, and in none of them could there be detected the slightest physical sign of lung involvement None of them have shown the rose colored spots In some, splenic enlargement could be plainly detected There was sometimes tenderness in the epigastric, or in the right iliac region, but often these signs were wanting All of them reacted to the urine and blood tests, and as a rule each test appeared early in the disease, the diazo reaction almost invariably appearing first

Class 3—Pneumonia, 7 cases, severe acute bronchitis 10, amygdalitis 3, otititis media 1, pleuritis 2, peritonitis 1, renal hematuria 2, cystitis 1, periostitis 1

I would call attention to this as a very interesting class of cases In 23 of them there is a suspicion that the respiratory tract was the point of invasion of the infection Sicard[1] believes that one tenth of all cases are infected in this manner Henrots'[2] report of 112 cases of typhoid fever among a troop of 1600 soldiers, who during a sham battle passed over a very dry and dusty field which had been fertilized with human excrement, would indicate the respiratory tract as a point of invasion of the bacillus typhosus, especially as it was noted that a great number of them had pneumonia and other pulmonary complications Flexner's[3] case, in which the typhoid bacillus was found in the lung, liver and spleen, while the intestinal mucous membrane was normal, and the mesenteric glands not enlarged, would seem to add additional weight to this theory There is abundant evidence in the recent literature of this disease to show that the intestinal lesions are not a necessary part of its pathology Nichols and Keenan[4] have recently reported a case and collected nine others in which no lesion of the intestine was found, although the typhoid bacillus was cultivated, usually from the spleen Sanarelli[5] maintains that the disease is, properly speaking, not an intestinal one, that the spleen and lymphatic system are the points where the bacilli produce their peculiar toxins, and the intestinal lesions are due to secondary causes Osler[6] makes the clinical observation that "the severity of the symptoms of typhoid fever bears no relation to the extent or intensity of the intestinal lesions"

There have been two deaths, a little less than 1 per cent This is not mentioned to bolster up any particular treatment, but rather, to show the fallacy of mere figures, unconnected with other facts, when used to prove the efficacy of any so called abortive treatment One-third of these cases have either aborted before the tenth day or run a course so mild as to make the diagnosis of scientific interest without the use of the particular remedies which are claimed to produce these results While not decrying medicinal treatment in this disease, the writer believes that other factors play a much greater part in affecting the mortality The attenuation of the specific infection, the amount received, the individual resistance or degree of immunity, may be mentioned among these factors and the peculiar circumstance of this epidemic would tend to show that at least one of them had much to do with lessening its severity

It is desirable to call attention to the value of the chemic and bacteriologic tests in the diagnosis of this disease In a former article[7] the writer has shown the relative values of these two tests The diazo-reaction appeared first or at the same time in 80 per cent of the cases in which it was used side by side with the serum test It has failed to appear in 12 out of 200 cases, and in only one of these was it fairly tried It almost always appeared before the eighth day, even in the mildest cases, but in some of these it is present only on one or two days To be certain that it has not appeared, tests should be made daily Although it is found in some other diseases—measles, scarlatina, parotiditis, varicella, tuberculosis and cancer—by careful attention to the clinical symptoms, this test is a valuable aid in making an early diagnosis in typhoid fever Simon's[8] method, with Green's[9] modification of the formula, has been used and no test accepted unless a pink or rose color was given in dilution with five to ten parts of water

The serum test is the anchor in the diagnosis of this disease, and is very nearly, if not quite, pathognomonic Dr Wilson,[10] assistant bacteriologist to the Minnesota State Board of Health, has made 1150 tests from 365 of my patients Wyatt Johnston's dried blood method with dilution of about 1–25 was used in about one half the tests, and Dr Wilson's[10] method of collecting the blood on aluminum foil, weighing and diluting it accurately to 1–25, was used in the latter half Of those cases in which the reaction was negative throughout, one was typic typhoid fever clinically Two others were [illegible] fants ten weeks old whose te[illegible]rature ran[illegible] to 103 for three [illegible] had ras[illegible] typic

They had diarrhea, distension of the bowels and enlarged spleen The urine of each gave diazo reaction throughout the illness They had been partly bottle-fed, the family using infected water No other members of the family had typhoid fever One other case of doubtful diagnosis was reported by the writer[11] in a former article These four would make a percentage of about 1 8 in which the reaction was absent On the other side there were two cases, one of which has been reported,[12] in which the reaction was present during the course of another disease, in which there was at least a suspicion that typhoid fever was not present The second case was one of severe erysipelas, during the course of which the serum reaction appeared on the fifteenth day The spleen was enlarged, and there was diarrhea with characteristic stools There was at the same time another case of typhoid fever in the family

Gwyn's[13] case of typic clinical typhoid fever with rose spots, diazo-reaction, hemorrhage from the bowels, serum reaction negative, in which cultures from the blood showed only Gaertner's bacillus, may throw some light on such reports as Brill's,[14] who, in seventeen cases clinically resembling typhoid fever found the serum test negative And further research along this line may prove Widal's test pathognomonic of infection with the bacillus typhosus

CLIMATIC VERSUS SERUM TREATMENT OF PULMONARY TUBERCULOSIS

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10, 1898

BY F E WAXHAM, M D

PROFESSOR OF MEDICINE AND LARYNGOLOGY, COLORADO SCHOOL OF MEDICINE
DENVER, COL

The climatic treatment of disease is a most important subject, and one that I am convinced has not been fully studied and appreciated No doubt many failures are to be attributed to the fact that neither proper cases nor proper climate have been selected Because a patient has tuberculosis is no reason or excuse why he should be sent two thousand miles or more from home and comfort and friends, only to find, perhaps his malady increased, and to die among strangers We should prescribe a change of climate with as much discretion and judgment as any other remedy Whether a patient should be sent from come in search of health will depend upon several conditions The stage of the disease, the vigor, vitality, disposition of the patient, and the means with which to live comfortably, are all to be considered Physicians in the Rocky Mountain region are continually meeting with cases that should never have been sent to this country Too frequently we are obliged to advise their immediate return Tuberculosis in the last stages is only aggravated, and the condition of the patient made worse and more uncomfortable by a residence in this altitude

Climatic treatment, like any other treatment of disease, should be applied early The earlier the application of the remedy, the more certain and positive the results It may be said, with little fear of contradiction, that tuberculosis in the first stage, and often in the second, is cured by a proper change of climate In selecting cases for climatic treatment, therefore, by all means select the early ones Do not wait until the golden opportunity is lost in the hope of arresting the disease by less effective measures

It must be stated in this connection, however, and it must be admitted, that tuberculosis originating in this climate, as a rule, runs a rapid and unfavorable course This has been the observation of those who have had the opportunity of watching these cases It has been my misfortune to have met with a few such patients, and they have formed no exception to the rule

There is another factor of no little importance that should be considered in the selection of cases appropriate for climatic treatment, and that is, the financial circumstances of life Many seem to entertain the impression that no matter what the stage of the disease, if they can only live to reach this land of promise, their ills will take wings, they will find ready employment and health will soon be restored By the irony of fate, many find no employment, and, as a result of anxiety and forced economy, the ills are increased If a patient's circumstances are such that he can not live in comfort and idleness, if necessary, for at least a year, it would seem hopeless to send him in search of health Something more is needed than mere climate A contented mind, freedom from worry and anxiety good and abundant food and cheerful surroundings—these are all essential factors I contend that it is more humane to allow a patient to die in peace at home, even if his days are shorter, than to send him in the later stages away in search of health, unless he has means with which to command every comfort

The selection of the proper climate is quite as important as the proper selection of cases There is no climate suitable to all cases, although in general terms we may say that the essential features are altitude, dryness, abundant sunshine, and uniformity of temperature Wherever these conditions prevail, a tubercular patient has the best chance to recover Early cases, with no heart lesions do best, as a rule, in a high altitude with its invigorating and stimulating atmosphere These are the cases that do remarkably well in Colorado More advanced cases need a warmer and a less elevated climate Such cases do better in New Mexico, Southwestern Texas, Arizona, or the interior of Southern California Many cases do well in Colorado during the summer and fall, but do not bear well the cold of winter, and it becomes necessary for them to go southward during this season, and, again, there are many who do wonderfully well in winter in New Mexico, Texas or Arizona, but who can not endure the heat of summer in those regions It becomes necessary, therefore, to shift a patient about from one climate to another in order to take advantage of the best seasons until he has recovered

Another important consideration is the fact that tubercular patients recover slowly It requires from six months to three or four years, according to the condition of the patient and the stage of the disease, to entirely recover, and even after this period it is usually necessary for a patient to live in that climate where he has recovered, or a similar one Too frequently patients come to this country with the idea that within a very few months their disease will be eradicated in some magical way, and that they can then return with safety to their eastern homes This is a most erroneous impression, and should not be encouraged The earlier the cases are recognized and sent to appropriate climates, the more likely that they will be able to return to their eastern homes, providing every vestige of the disease has been eradicated Such patients must, however, be prepared to flee for their lives on the slightest return of their malady As a rule, we can not trust them, and they will remain long after they have been warned, and often until it is too late to regain the lost ground The success of climatic treatment will, therefore, not only depend upon the proper selection of climate, but upon the proper selection of cases as well

At the present time the serum treatment of tuberculosis is attracting widespread attention The almost specific action of antitoxin in the treatment of diphtheria has inspired many of our best and brightest men to seek a like remedy for the cure of that arch enemy of the human race—consumption At the present date it is generally admitted that the serum treatment of chronic tuberculosis is disappointing It remains yet to be proven whether it is effective in the early stages If it produces immunity, if it arrests the progress of the disease in incipient cases, it still remains to be proven how long the immunity continues

If antitoxin is nature's remedy for overcoming disease, it would seem that in a disease which is essentially chronic, with no tendency to self-limitation, if immunity is conferred it would be necessary to supply the system continuously and indefinitely in order to preserve the immunity and to prevent relapse A patient with tuberculosis in its early stages may be cured by the administration of antitoxins Will he remain cured and how long are equally important considerations In diphtheria it has been proven that the immunity produced by antitoxin in full protective doses lasts at most only three weeks Is it reasonable to suppose that an antitoxin for tuberculosis would produce immunity for a longer period? If a patient's environment is not altered, if the same conditions and surroundings exist after as before treatment, or if the patient again inhales the fatal bacillus, will there not be a return of the disease?

It has been proven beyond all doubt that proper climatic treatment almost invariably arrests early tuberculosis I will not occupy the time of this society by reporting cases to prove this assertion That even many late cases improve and remain in a fair degree or health for years, and that many second stage and most (at least 90 per cent) of the first stage cases, entirely recover, is a fact so well established that it is unnecessary for me, on this occasion, to enter upon a detailed history of cases It is true, however, that with very few exceptions a patient can not return to a low altitude and previous environment without great danger of the redevelopment of the disease The immunity conferred by climate is thus lost Why should this be so? We recognize that altitude, pure air, sunshine and uniformity of climate are essential factors in promoting the cure of tuberculosis Why ? May it not be because these conditions invigorate the system and stimulate the production of the normal antitoxins of the body? May this not be the reason why immunity is lost sooner or later when a patient cured by climatic treatment, returns to former conditions and surroundings? If climatic treatment must be ontinuous in order to preserve immunity, is it not equally true that the artificial introduction of antitoxins into the system must also be continuous in order to maintain immunity? The brilliant work that has been done the past few years in the bacteriologic laboratories of the world presages victory in the discovery of a remedy for tuberculosis There are, however, unseen forces that must yet be understood and overcome The mysteries and difficulties of artificial antitoxin production and application are distracting and apparently unfathomable, but it ill becomes any man to say that these difficulties and mysteries will not be solved

Until we have more light to guide us, until we are more fully convinced of the utility of the serum treatment of tuberculosis, we should continue to take advantage of climatic treatment, which has been fully tried and seldom found wanting

---

A FEW CONSIDERATIONS REGARDING CLIMATIC CHANGE AND SERUM THERAPY IN PULMONARY TUBERCULOSIS

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY S G BONNEY, AM , M D

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF DENVER, VISITING PHYSICIAN ST LUKE'S HOSPITAL
DENVER COLO

If an apology is necessary for the introduction of that concerning which so much has already been written, it is found in the vast importance of the subject, the wide diversity of opinions, the rather general absence of clearly defined knowledge and the increasing mass of literature extolling without limit the virtues of special methods of treatment It is not my purpose to advocate unduly the adaptability of any climate or climates to the various stages of the disease To present a plea for the more rational and conservative measures of treatment in a climate appropriate to the individual case, in opposition to the present employment of serum-therapy in its various modifications, is the object of this paper As a preliminary postulate, I will submit that climate in conjunction with painstaking attention to details of management offers to the pulmonary invalid greater assurance of improvement than can be otherwise obtained

Waiving for the present the acceptance of this proposition, it is perhaps well to allude briefly to the errors of judgment often observed in the early history of pulmonary tuberculosis prior to arrival in Colorado I do not refer merely to mistaken or deferred diagnosis with its unfortunate results, but more especially to the ill-considered advice imparted, when the nature of the condition has at last become clearly established The temporizing delay at this stage of the disease, more important than any other, forms too frequently a portion of the evidence which may convict the medical adviser of culpable and contributory negligence I have been impressed repeatedly and forcibly, *from a study of my records that the vast* majority of the pulmonary invalids in Colorado arrive only after moderately active and extensive infection has taken place It is by no means infrequent in my experience to feel compelled to advise an immediate return for the unfortunate who has but finished his journey of one or two thousand miles only to find that he has come too late The history of such cases usually discloses the duration of a several years' illness, with ample opportunity for earlier climatic change had it been advised or properly insisted upon It is pertinent to state that out of a total of 350 selected cases which have remained under my supervision, more than half presented themselves with extensive pulmonary involvement averaging about a year and a half subsequent to the recognition of their condition The fact that 213 of the cases in the entire list came to Colorado with pronounced signs in each lung should emphasize, not only the necessity of earlier diagnosis, but the wisdom as well of more prompt climatic treatment

The patient with pronounced physical signs of pulmonary tuberculosis often states upon arrival that he was advised by his physician to remain at home during the summer and early fall and prepare to visit this climate for a few months in order to escape a bad winter The history almost invariably shows a progressive decline in weight, strength and appetite, with increase of fever, cough and expectoration during the so-called favorable season at home He consequently arrives in Colorado less prepared to respond to the influences of her climate, and is deprived, for the year at least, of a considerable portion of her most favorable and delightful season Others, after one or two years' illness at home, are frequently instructed to come to this State for a definite period, of perhaps three to six months, regardless of climatic results As a matter of fact, many such cases do not live out their expectancy in Colorado

It is interesting, but discouraging, to note the large proportion of cases coming here as a last resort A reference to my records show that a very considerable number of cases first sought climatic change elsewhere When it is considered that the distinctive climatic conditions in Colorado are especially applicable to the early cases and contraindicated for those with the most extensive infection, the true significance of such procrastination will be more fully appreciated This would be less worthy of comment were it true that a recourse to only a few localities was usually observed before a resort to Colorado The unfortunate fact remains that in a great many instances the patient has exhausted the climatic influences of the entire country in a vain effort to secure arrestment, before applying to Colorado as a court of last appeal As a fair illustrative example I will cite the following brief and imperfect report Mrs X, aged 29, New York State Arrived in Colorado Feb 11, 1898 Present illness began October, 1896 Two months later was sent to Thomasville, Ga Remained two months, improved, was directed by her physician to Aiken, S C, remained one month, gained Returned to New York, remained three months and failed, successively sent for short periods to Canada, Northern New York, Bethlehem, N H, and advised to return to New York City, where she was for three months under daily inoculations with oxytuberculin She was finally sent to Colorado, one year and four months after recognition of disease, equipped with special hypodermic syringe and a full complement of the tuberculin, but with exhausted energies, depleted finances and extensive infection of both lungs, moderate pyrexia, severe distressing cough with copious expectoration, disturbed digestion, loss of weight, cardiac excitement and insomnia I will state that the patient is improving at the present time and is likely to remain for a considerable period in Colorado, in spite of the adviser in New York, who is, even now, counseling another change It seems strange that patients should receive directions to keep constantly on the move, irrespective of adaptability to climatic conditions and of benefits already received in any location

It is to be regretted that certain physicians have seen fit to order their patients away from home with instructions to beware of the doctors, or at most, to secure an opinion as to results obtained after the lapse of several months Unfortunately many of these are compelled to seek medical aid much sooner than anticipated as a direct result of the injudicious counsel of their home advisers, with reference to exercise, work or manner of living It is safe to say that nearly one-third of the pulmonary invalids seeking direction in Colorado for the first time, present the history of several months' residence in the State, usually under decidedly improper conditions and with unsatisfactory results thus far attained

The spectacle is also occasionally witnessed of the physician, who has perchance never been in this region, presuming to dictate in advance, or later at a distance of 1000 or 2000 miles, the policy of therapeutic management There came under my observation not long ago a young man from an eastern city who, during a period of six months' residence in Colorado, had prepared fortnightly cover-glass specimens of the sputum, to be mailed to his physician in the east The cheering intelligence was regularly returned that the bacilli were diminishing in number and that favorable progress was being maintained The actual results attained were as unsatisfactory as could have been expected from the character of the medical advice It does seem that there should be a tremendous liability for such errors of professional judgment as are responsible for the loss of human life and happiness, and for which there can be said to exist no extenuating circumstances From the history and character of the cases almost daily coming under observation in this climate it would appear that the medical counsel was occasionally delivered without the encumbrance of knowledge or the handicap of conscience Is it not fitting in a discussion of this character to enter an emphatic protest against the indiscriminate character of the medical advice frequently given with reference to the question of an appropriate climatic change? As far as pertains to Colorado, I can only report that cases suitable for this climate should come early, come to stay, and come prepared to receive competent counsel

Despite the rather unsatisfactory character of the cases generally observed in this State, the combined results of climatic influence and management are nevertheless extremely gratifying From my own experience and that of my colleagues in Colorado, I am sustained in stating that, in round numbers, from two-thirds to three fourths of all cases taken as they come may be expected to exhibit pronounced improvement under proper conditions Instances of incipient pulmonary involvement constituting, as they do, but one-fifth of the entire number, show material gain if not permanent arrestment, in nearly four-fifths of these cases If with slight tubercular infection is combined other favorable considerations with reference to temperament, nervous system, digestion finances, and domestic relations, the percentage of improvement in such instances is raised to 90 The authenticity of these statements is subject to verification by a reviewed analysis of my own recorded cases and the reported observations of others The significance of these figures is remarkable in view of the obvious difficulties constantly experienced in maintaining a strict and proper regimen for somewhat indefinite periods The fact that but one-fifth of all the cases observed in Colorado are incipient ones, and that the accorded results of the climatic change are not relatively increased, reflects a certain responsibility upon the general profession and offers a justification for these remarks

In the midst of the present enthusiasm and interest in the treatment of pulmonary tuberculosis, the laudable search by strictly scientific men for new and specific remedies, the undue haste in heralding the results of serum-therapy as applied frequently to a limited number of cases totally devoid of adaptation to the means employed, and in the midst of the unfortunate tendency to experiment with the various special methods in private practice, to the exclusion of climatic considerations and systematic management, let me ask, "What have been the ultimate authentic results?" It is comparatively easy to sound the praises of certain methods and ingenious appliances, but, after all, "the proof of the pudding is in the eating' Have the patients shown a satisfactory and enduring improvement? The arguments should be summed up and conclusions reached with reference to the practical results upon the unfortunate consumptive, rather than from laboratory inferences derived from guinea pigs The alleged immunization of this animal is of but slight interest or value to the pulmonary invalid, if the modified tuberculin preparations are to continue to exert their distinctly deleterious influence upon the course of the disease What well-substantiated clinical evidence has as yet been adduced to justify, in the slightest degree, the increasing employment of such preparations outside of carefully-conducted experimental institutions? Great interest has been attracted of late to the new tuberculin of Koch, the derived serum of Fisch, and the oxytuberculin of Hirschfelder The later German consensus of opinion upon tuberculin preparations may be safely considered to reflect more favorable estimates upon their present utility than could be generally entertained elsewhere in any responsible manner The extent of German disfavor upon the use of the new tuberculin, from the latest clinical reports, is well understood Numerous authorities in Europe, from their own personal experience, have unhesitatingly stamped their disapproval of its employment The following from the *Philadelphia Medical Journal* of March 12, 1898, possesses much significance in this connection

> At the last three meetings of the staff of the Charité Berlin's largest public hospital, the therapeutic worth of Koch's new tuberculin was discussed It is now in use over ten months and some definite conclusion as to its specific therapeutic efficacy, it would seem, should be given to the profession at large, who look to those with hospital opportunities and material for practical results Not a single voice was raised in its favor, except that of Professor Brieger, Koch's assistant in the institution for infectious diseases, and even that voice, it must be confessed, in somewhat apologetic tone rather than in any convincing way

The *Medical News* of March 19 1898 contains an interesting reference to the clinical discussions at the Charité and to the absolute failure to produce immunization in animals with the new tuberculin It states

> The experiments seem to have been carefully carried out, the dosage of tuberculin was exact and sufficient and the observations numerous enough to do away with the idea that perhaps coincidence played a rôle in the results obtained, and yet there was utter failure to get the desired immunity After supposed immunization, all the animals died when inoculated with tuberculous material, and, interesting enough, most of them before the control animals inoculated with the same material at the same time The history of the second tuberculin forms an interesting commentary on the enthusiastic reception of the first In Berlin it has had practically the effect of destroying faith in all so called specific remedies for tuberculosis Constitutional treatment is now the only method receiving any attention

Subsequent to the decision of the Académie de Médecine of Paris, that the therapeutic value of oxytuberculin had not been established by sufficient experimentation, a committee of the Cooper Medical College of San Francisco was appointed to institute an investigation and render a detailed report upon this remedy The committee has bestowed its unqualified endorsement of oxytuberculin and urged its extended use From a review of the published evidence presented to the committee, upon which its findings were based, I am unable personally to accept their conclusions, on the ground of insufficient clinical testimony The reported results of other observers, as far as I am able to ascertain, have since been quite unsatisfactory My own experience with various tuberculin preparations, save for occasional diagnostic purposes, has been limited to observation of results from their antecedent employment I have never considered the request of the patient for the use of tuberculin a sufficient justification for its administration, adjudging this to be in the same category with similar appeals for morphin or the performance of ovariotomy if contrary to the judgment of the attending physician Despite protestations to the contrary, from lay and professional sources, the patient is unable to assume the entire burden of responsibility in such cases

A very considerable number of cases have subjected themselves to my care, presenting the history of several months' daily inoculation with tuberculin preparations prior to arrival in Colorado In none of these have I been able to secure a statement of favorable results attending its employment, save in the occasional instances of conjoined climatic influence The record has almost invariably shown subsequent failure, which with the involved loss of time, in early stages, must constitute a factor of no mean importance It is manifestly fair, for the purposes of comparison, to allude briefly to those who have come under my observation, following the use of various tuberculin injections in Colorado under the same climatic conditions Admittedly a certain proportion of such cases should be expected to exhibit improvement from the climatic change irrespective of therapeutic management I have been rather surprised therefore, to note the generally unsatisfactory results attained by those in this class whom I have had opportunity to observe I can recall no instance in which, from a review of the history of the case after arrival, material improvement could be inferred to have taken place during the inoculations Of further significance, I can conscientiously report a marked gain in the majority of such cases upon cessation of special treatment and the observation of rational methods with strict insistence upon appropriate daily regimen

Relative to the reported experience with tuberculin preparations of some of my colleagues in Colorado, I can not refrain from the statement that I can see no justification for their employment in this State, nor any scientific value to be derived from such observations It is recognized by even their warmest advocates that their use should be limited chiefly to early cases It is precisely such cases that have been demonstrated to respond most readily to the favorable influences of the climate I submit the proposition that such cases, showing an exceedingly large percentage of improvement from climatic conditions, should not be lightly subjected to the influence of a powerful agent, the utility of which as yet remains undemonstrated by clinical experience or laboratory investigations I insist, also, that the improvement reported in early cases during the first year in Colorado is no evidence that benefit was derived from the coincident employment of serum-therapy Further, inasmuch as the use of tuberculin preparations is not considered to be generally applicable to cases with more extensive infection, there would seem to be still less excuse for its indiscriminate administration in Colorado in cases to which this means is not adapted according to its most experienced and enthusiastic supporters

It has been suggested by some that the moral effect, if nothing more, of daily inoculations should exert a favorable influence upon the pulmonary invalid This is presumably advocated from the apparent hopelessness of many cases, the inability for various reasons to enforce proper therapeutic management, and the desirability of producing a suitable impression upon the patient to the effect that definite means are being constantly employed for his relief I am convinced, from my own experience, that the moral effect of this is distinctly bad I have repeatedly had occasion to observe the increased susceptibility of pulmonary invalids to depressing or exciting influences The mental effect of the daily subjection of such patients to this procedure, with the prolonged confinement in the physician's office, with its incidental annoyances, must necessarily be disturbing and depressing Added to this, should be considered the enforced infringement of systematic management pertaining to an unbroken period of rest with as many hours daily of sunshine and of fresh air as possible, removed from the thickly settled portion of a city like Denver The trip to town, with its frequent delays, is sufficient to completely destroy the entire system of regimen for the half day at least, interfering with proper nourishment between meals, interrupting naps, or periods of rest, and affording varying degrees of physical exhaustion, with disquieting if not depressing mental influences

I have found it to be comparatively easy and infinitely more satisfactory to appeal directly to the intelligence of the patient by a judicious explanation of the situation, securing thereby a more active and hearty co-operation The personal influence of the local physician, with the establishment of confidence and trust, is calculated to produce an effect for good far greater than the moral influence of routine hypodermic injections

I present these very common-place remarks with much hesitation, but with the conviction that relative to a subject of such importance no harm can result from a plain statement of facts gathered from personal experience

ACCIDENTS IN EYE OPERATIONS

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10 1898

BY F C HEATH, M D

SECRETARY OF INDIANA STATE MEDICAL SOCIETY EYE AND EAR SURGEON TO UNION STATE HOSPITAL, AND CITY HOSPITAL AND DISPENSARY
INDIANAPOLIS IND

While it is more flattering to one's vanity to record successes, it is often quite as profitable to study failures and embarrassments, with a view to learning how to avoid or master them in the future It will be the aim of this paper to consider briefly a few accidents occurring in eye operations

Some years ago, as I was making a paracentesis on an Irishman's eye with a Graefe knife, the patient made a sudden violent movement on the entrance of the knife point into the anterior chamber A serious accident in this case was avoided by depressing the handle of the knife quickly so that the point could not injure the lens, but a good lesson was learned—*not to operate too soon after instilling cocain* A more serious accident occurred on attempting to do an iridectomy, without an assistant, on an intractable patient who moved her eye violently at the worst possible moment, causing considerable irido dialysis In this case two mistakes were made The first was in attempting to use the scissors with the left hand it is much easier to operate with the scissors in the right and forceps in the left hand I am inclined to think, however, that it is usually a mistake to do an *iridectomy without an assistant*, although I have many times done so successfully, and many will agree with Dr Reeves' statement at the Montreal meeting of the British Medical Association that "it is better to operate alone than to have unskilled assistance, if such a term can be used"

Of greater interest than these are my embarrassing experiences in three cataract cases, and they form the occasion for writing this paper In case first the combined operation was performed On cutting the iris the hemorrhage was profuse, the anterior chamber was soon filled completely and the blood could not be removed in the manner ordinarily advised, nor any other so far as I could see at that time The capsulotomy and delivery was therefore done in the dark, so to speak, and considerable cortical matter remained The blood was absorbed in a day or two and the eye healed rapidly, but the lens matter uniting with the capsule formed a secondary cataract This was left to nature, and while absorption was slow the patient ultimately obtained very useful vision Possibly using a cold compress for some time to cause the blood to coagulate, and then removing the clot with forceps, would have obviated all difficulty as to extraction of the lens in this case

Case second was most unfortunate This patient had the most deeply seated eyes I ever saw, which not only increased the difficulties of the operation, but made subsequent examinations very difficult and unsatisfactory, as the upper lid could not be raised without touching the inflamed eyeball Although the patient saw well at the close of the operation, and I could not see any lens matter remaining, I felt that

I had failed to make a complete delivery Later on some loose lens matter was found forcing apart the lips of the wound and was easily removed, but it had already set up a cyclitis which was followed by sympathetic inflammation of the other eye, necessitating enucleation of the exciting eye The result was particularly deplorable, as the sight in the remaining eye, upon which I had done a successful extraction the previous year, was considerably impaired There was additional disappointment, perhaps due to the fact that I had done double cataract extractions on two of his friends with a resulting vision of nearly 20/20 in each eye Earlier removal of loose lens matter might have prevented the cyclitis, and earlier enucleation would certainly have been better for the sight of the other eye, but this case was at a distance from me and could not be seen as often as I wished

In case third the nucleus of the lens with the thickened capsule dropped down into the vitreous, the capsule remaining attached above so that it swung as if upon a hinge Efforts to get hold of it and extract failed, although a properly made wire loop might possibly have been used successfully The eye was closed and a cool compress of cotton applied for a half hour, in the hope that the anterior chamber would refill and the lens float back into position, as it were At the end of that time, the aqueous showing no tendency to reform and the cornea remaining depressed or collapsed, the usual dressings were applied A little vitreous had been lost and its appearance indicated the occurrence of liquefaction At the end of twenty-four hours the anterior chamber was re-established and the lens had come up into place It was then a question whether to attempt its immediate removal or leave it to nature (supplementing what nature failed to do in the way of absorption by a secondary operation later on) The success of this course with case first, and the fact that the patient was a nervous invalid, led to the adoption of the latter plan The corneal wound healed kindly and there was but little iritis, slight adhesions below serving to fix the lens and capsule more firmly in place The iritis having subsided, we began to consider the question of a secondary operation, when the patient, who had long been an invalid, commenced to decline and soon died from causes having no connection with the eye or operation It is, therefore, a matter of speculation whether it would have been wiser in this case to have gone down into the vitreous with a wire loop immediately, or attempted the extraction of the lens remnant the day following, in lieu of the conservative course adopted I hope this phase of the subject will be thoroughly discussed

The text-books at my command say comparatively little about accidents in operations deSchweinitz gives the most, but even he does not cover all the points connected with such cases as I have here reported Of such accidents as the iris falling in front of the knife I have had no experience, nor have I ever lost much vitreous In one case only have I been compelled to enlarge my corneal incision The accidents mentioned in this paper have been the worst in my experience, but they have taught me such valuable lessons that I thought it might be more profitable to report them than my successes, hoping that the discussion thus introduced might bring out many points of value to those who feel there is yet something to be learned in this branch of our art

17 West Ohio Street

AN INEXPENSIVE 60-LENS OPHTHALMOSCOPE WITHOUT REKOSS-DISC

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7 10 1898

BY GEORGE M GOULD, M D

PHILADELPHIA

It is said that if within five years after graduation an oculist does not devise "A New Ophthalmoscope" his wife and intimate friends begin to make mysterious visits to the best alienists concerning the man s mental condition I have concluded that it will not do for me to hold out any longer The little device I show you today is designed to give the working oculist an instrument with double or treble the number of useful lenses in the ordinary ophthalmoscope, without the complicated and bothersome Rekoss-disc, without a handle, that does not need a case, and that is comparatively inexpensive The lenses are arranged in two sets independent of each other, each set in parallel continuous grooves or channels similar to the Morton instrument in this one respect Each set of lenses is propelled by a drive-wheel operating a toothed wheel for each of the two sets of lenses, this having a disc on which is the designation of the particular lens at any time before the sight hole The set of lenses in one end of the ophthalmoscope contains the lenses most used by an emmetropic oculist, and all the rarely-used lenses are in the set at the reverse end A highly ametropic oculist could have a different set of lenses placed in the most used end according to his personal needs The mirror, instead of tilting to either side, is reversible on its axis and thus can be placed at any angle desired for use when patients are in bed or with the light in any direction The mirror is readily taken out and inserted in either end of the instrument Side-illumination is excluded by a tube containing the mirror and the body of the instrument The instrument itself is used as a handle The arrangement of the lenses is as follows

At one Extremity (that most used)		At the other Extremity (that less used)	
Concave	Convex	Concave	Convex
		8 00	8 00
		8 50	8 50
0 50	0 50	9 00	9 00
1 00	1 00	9 50	9 50
1 50	1 50	10 00	10 00
2 00	2 00	10 50	11 00
2 50	2 50	11 00	12 00
3 00	3 00	12 00	14 00
3 50	3 50	13 00	16 00
4 00	4 00	14 00	18 00
4 50	4 50	15 00	20 00
5 00	5 00	16 00	25 00
5 50	5 50	18 00	30 00
6 00	6 00	20 00	
6 50	6 50	25 00	
7 00	7 00	30 00	
7 50		40 00	

The present crude instrument, the first one made, is designed to show its essential principles and methods, the finished instrument will be made of aluminum, and therefore much lighter in weight

---

DEMONSTRATION OF AN "AUTO FUNDOSCOPE

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10 1898

BY GEORGE M GOULD, M D

PHILADELPHIA PA

The little device for which I have dared to coin the terrible word "Autofundoscope," is a very simple bit of mechanism, designed to slowly and accurately revolve a pin-hole through, and placed about two millimeters from, the center of a black rubber disc. The word should have been *autoretinoscope*, but as *retinoscopy* has been given another signification, *autofundoscope* is the only word left to designate the observation of the vascular system of one's own retina. The method essentially is the very old one described in books on physiologic optics of moving a pin-perforated card, held in the hand, before the eye, and observing an illuminated blank space through the perforation. In this way, however, one secures only faint, movable and indefinite images of the retinal vessels, which disappear and reappear with provoking rapidity. The common newspaper puzzle of revolving concentric alternate circles of black and white rings, when upon stopping the movement, the circles seem still to revolve, suggested to me this improvement and device. Both facts rest upon conditions explained in books on optics, which you well know—the position of the capillaries in front of the retina, the shadows they cast, the physiologic influence of fatigue, and the slight change in the position of the shadows affected by the revolving perforated disc. One may place the instrument, without the tube, five or ten feet from a brilliantly illuminated white card-board, and thus obtain a very fair and steady image of the macular region and the entire perimacular vascular system. A little patience and considerable care is needed to hold the eye very steady at the right angle, and to rotate the disc at exactly the requisite rapidity and uniformity to bring out the image most perfectly and immovably. Had I thought the experiment worth the expense and trouble, it would have been possible to provide an automatic clock-work mechanism much superior to the present crude device.

Physiologically the method is something more than a curiosity, as showing one the exact shape and relative dimensions of his yellow spot of Sömmering, or macular region, the comparison of the different picture of the two eyes, the perfection of the vascular supply of the retina, etc. I have been astonished to see how clearly the finest capillaries are seen, how much closer they penetrate to the macula than I supposed, etc.

I can imagine that the method may have use in demonstrations of pathologic conditions, but all such must depend upon the fact that it is only one's own retina that one can thus see. I have noticed in my own images certain opalescent spots in the perimacular space, invariable in each eye, though entirely different for each, in size, number and location. I do not know what causes them. They are not muscæ.

THERAPEUTIC VALUE OF SOME MEDICINAL AGENTS IN PHYSICAL DISEASES AND SOME PSYCHICAL TROUBLES

Presented to the Section of Materia Medica, Pharmacy and Therapeutics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY T. B. GREENLEY, M.D.

MEADOW LAWN, KY.

It has occurred to me that a short sketch of the value of a few remedies I have used with good results in certain cases, might be appropriate.

First, I will speak of spirits of turpentine. I have found it to be one of the best antihemorrhagics I have used. I regard it almost as a specific in hematuria. Within the last year I have had some ten cases of this trouble. I give small doses frequently repeated, say fifteen drops at intervals of three or four hours. As a matter of convenience I give on sugar in a teaspoon, instead of preparing an emulsion. Of course, in order to aid the action of the remedy I freely employ dry cupping over the kidneys. Usually in twenty-four to thirty-six hours the bleeding is arrested. In hemoptysis, either from the stomach or lungs, it is an admirable remedy, especially so when due to trauma. I also use it in hemorrhage from the bowels and uterus. In the latter case ergot would greatly assist the turpentine. In oozing of blood from the surface of a wound, it is not only antihemorrhagic, but also antiseptic, and at the same time exerts some healing property. In cases of bowel affections, where flatulency is present, turpentine serves an admirable effect in its relief. The most painful and unpleasant symptom in typhoid fever is flatulency of the bowels. Turpentine in such cases is our best remedy. Beside removing the painful distension of the organs, it also serves as an excellent antiseptic. It is also a fairly good vermifuge. In old times when intermittent fevers were so prevalent in the Ohio valley, and quinin so high priced, and when I had so much charity practice to do, I studied up an antichill medicine, of which turpentine was the principal ingredient. It had the desired effect in arresting the disease. As quinin at present is so low in price, it is not worth while to speak of the formula.

In speaking of the virtues of turpentine, I do not wish it understood that I regard it a king cure-all, as some of the patent medicine proprietors assert their preparations to be.

Next I would mention ammonium chlorid as an alterative in certain hypertrophies, etc. I have used it in enlargement of the spleen and liver with very happy effect. A case of the largest spleen I ever saw was that of a lady about forty years old, who lived in a very malarious locality. The organ had extended considerably across the median line, producing quite a prominence of the abdomen. I put her on the chlorid and continued it several months. The spleen gradually became greatly reduced, relieving the patient of much discomfort from weight and distention. While using the chlorid, I had the patient apply irritants, such as tinct. iodin, turpentine, etc., over the abdomen, and two or three times drawing blisters with fly plasters. These agents were aided by adjuvants in the way of tonics and laxatives, as quinin, etc. The patient finally recovered her usual health.

I have also used the chlorid in hypertrophy of the liver with very happy results. In these cases, we have to use, aside from the alterative, such adjuvants as are indicated in each particular case. I was very much gratified by its use in a case of chronic pneumonia in a woman of some thirty years of age. Her acute attack occurred some six or eight months before I saw her. She was up and able to attend to her household matters, but complained of pain in her right side, and had a troublesome cough. On examining her I found consolidation of lower lobe of right lung. I put her on the chlorid of ammonia and blistered the surface over the part of lung involved. The suface was kept partially raw by repeating the plaster when necessary. At the end of four or five weeks the lung was restored to its normal condition. This treatment was aided by medicines to promote appetite and aid digestion, as tonics, etc The chlorid is one of my favorite remedies in sore throat, especially when it is accompanied with hoarseness I prepare a syrup of the following formula

℞ Ammonium chlorid
Sodium bromid
Chloral hydrate, aa ʒv
Syrupus simplex (½ pint) Oss
M and Sig Teaspoonful swallowed slowly

This syrup also serves as an admirable cough medicine In taking it for sore throat it should be swallowed slowly, as before remarked, and nothing else taken for some ten minutes or more, so as to afford time for its local action on the mucous surface of the throat

In irritable cough due to the effect of cold, in bronchitis or phthisis, where sleep is greatly interfered with, this syrup will be found a most admirable remedy On retiring take a teaspoonful and if not relieved in fifteen or twenty minutes repeat the dose, and as a rule, in a short time rest and sleep will be secured I keep this syrup, already prepared, in my office, ready to dispense in all such cases as those alluded to In cases where the cough is tight, I add a little syrup of ipecac to each dose

When a man practices medicine over fifty years it is not an unusual thing for him to have some favorite remedies or you might say hobbies in medicine I must acknowledge I am one of the old time fogies who believe we can not with safety lay aside our old pharmacopeial remedies for the late preparations in pharmacy, although I am not prejudiced against them and frequently use some of them

In some instances we can, with advantage, combine some of the preparations I have been fortunate in this respect in combining two of the chlorids as a quick alterative Some fifteen years ago I was called to see a child with membranous croup The little thing was in its mother's lap, gasping for breath, with sinking at the upper and lower end of the sternum I told its mother the baby was virtually dying She begged me to do something, and to gratify her I put up some medicine I had never used before in that disease, but told her I had no hope of relieving the child, as I had seen only one case in over thirty-five years get well I combined the protochlorid of mercury—calomel—with the chlorid of ammonia, one grain each, in powders to be given every two hours, the child being about fifteen months old It was in the morning, and I told the mother if the child lived through the day and night to let me know next morning When I saw her little boy coming to the house, I supposed he was sent to let me know the patient was dead, but happily, on inquiry, he informed me it was better and wished me to see it again I very gladly answered the request and found my patient greatly improved, in fact out of danger

Since then I have treated six other cases of the disease in the same way, with the same happy results I omitted to say that in conjunction with the internal remedies I had a towel, kept wet with warm water, applied around the child's neck, so as to keep the parts relaxed The only case of true croup I ever saw recover, before the widow's child above spoken of, was treated by the method recommended by Dr Green of New York, over fifty years ago He, with a piece of sponge fastened to the end of a whalebone probang, dipped into a strong solution of nitrate of silver, introduced it into the child's glotis I only tried this treatment in one case, the one before alluded to, and never had the heart to repeat it The treatment and its effect was explained to the parents, and as the child was nearly moribund, they requested me to do anything that offered any possible chance to save its life Dr Green had reported several cases cured by this plan of treatment In speaking of my plan of treating croup, it was feared by some that bichlorid of mercury would result, by the combination of the two chlorids, but I have never observed any unpleasant effects resulting from their union

In old times, as a general thing, we treated croup with emetics, syrups, etc, but only to look on and wait for death to relieve the patient Fortunately, membranous or true croup is comparatively a rare disease

Respecting the medicinal virtues of nux vomica, I have used this agent in the form of normal liquid, mostly, as a tonic and alterative, for many years I use it as a heart tonic in most cases of debility of that organ, in preference to the ordinary heart tonics, such as digitalis, strophanthus, convallaria, cactina, etc In cases of rapid action of the organ, digitalis for a short time might be preferable I also give it in debility of the muscular coats of the stomach and bowels, resulting in dyspepsia and constipation By toning up the muscles of these organs, relief is afforded in many instances I have also relieved paralysis of the bladder in a short time with nux and belladonna I have relieved one case of locomotor ataxia with these two remedies It was in the early stages of the disease

In regard to fads in medicine, I might say a few words respecting a favorite prescription I use in diarrhea I have used it for this trouble for several years, and find it almost a specific, especially so in summer complaint of children It is as follows

Paregoric	℥ ij	62	206
Ext witch hazel	℥ j	31	103
Carbolic acid	ʒ j	3	887
F Ext Kino	ʒ ij	7	775
Jamaica ginger	ʒ ij	7	775
Precipitated chalk	℥ j	3	887
Simple syrup to make	℥ viii	248	82

Mix thoroughly and always shake bottle well before dosing For an adult a teaspoonful is a dose, to be repeated at intervals of three hours, until desired effects result Dose for children in proportion to age

Perhaps I have said enough respecting favorite remedies, and will say a few words in regard to medicines which prove to have psychologic effects, or cure imaginary diseases It is frequently the case that such troubles come under our observation I am at times at a loss whether to term these cases psychologic or due mainly to credulity Sometimes I think a great many people are hypnotized by their credulity in the virtues of certain so called remedies, and will take them for months, or even years, for imaginary troubles In some cases of this character the so called remedy, by its long continuance, produces derangement of some organ or organs, if not actual disease I have known cases of this character We are occasionally puzzled how to treat successfully some cases of hysteria Patients of this class are easily affected by suggestion, and when we thoroughly acquaint ourselves with their peculiarities, we are much better enabled to manage them You have, in a great measure, to treat the mind In the first place gain their confidence that you can cure them I recollect having a case years ago, a girl about twenty years of age who was laboring under the belief that she was paralyzed in one leg and arm These spells of paralysis, I soon discovered, were intermittent in character When I learned this and got the run of her symptoms, as expressed by herself and her mother, I assured her that I could cure her I put her on a simple plan of treatment and requested her mother to be very particular in observing my directions I did this in her presence, laying a good deal of stress on small matters, such as massage of the parts diet, etc On my next visit she was a great deal better of the paralysis, but had a spell in the night different from any she had before Her mother described the symptoms to me in her presence and wished I had been there to see how she was affected I was well satisfied that after her mother's description of the attack in the night, I would soon see it repeated Sure enough in less than an hour a similar spell came on, which was of a convulsive character After it was over I called her mother aside and charged her not to speak of her case in the presence of any one again, as it was a suggestion to the patient to repeat the symptoms On my assurance that she would get well by observing my directions in every particular and that she would be well by the time I came back in two days, she was satisfied and was all right on my next visit

I might speak of another case of hysteria in a young woman who came to the conclusion she could not speak above a whisper She was apparently in good health otherwise I put up a little medicine to be taken at regular intervals, with a solution to be applied to her throat with a feather, at the same time she took the medicine and also used external applications, assuring her that by following the directions strictly she would be able to talk when I returned She was all right on my next visit She had not talked above a whisper for two weeks More cases of a psychologic character might be mentioned, but those alluded to are sufficient for the present occasion In fact we should, to some extent treat the mind in a majority of cases There are many patients of a more or less nervous temperament laboring under physical ailment, where assurance to the mind that they will get well is of great benefit

We as regular medical men, have now and then been charged and in some cases truthfully of administering bread pills in cases of imaginary diseases But our homeopathic friends can beat us two to one in hypnotizing a patient when there is not much the matter They will put up their granules of charcoal, chalk or sulphur and tell the patient to take them at regular intervals and strictly obey the directions about diet etc and he will certainly get well The assurance of getting well and the observance of the dietary are the elements of success in such cases It would be a good thing on our part if we would treat the minds of our patients more carefully than we do

---

Salophen in Articular Rheumatism —The gastric disturbances that frequently follow the prolonged use of sodium salicylate in rheumatism, can be avoided if after three to five days' treatment, and the disappearance of the principal morbid manifestations of acute articular rheumatism, salophen is substituted, giving 2 to 3 grams a day Salophen passes through the stomach unchanged, to be split into salicylic acid and acetylparamidophenol in the intestines, and can be administered without inconvenience until all fear of a relapse is past.—Professor Mosler of Greifswald, *Semaine Méd* , Sept. 7

THE SULPHOCARBOLATES

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY WILLIAM F WAUGH, A M , [illegible]
Professor of Practice etc Illinois Medical College [illegible] cago Summer School of Medicine
CHICAGO ILL

The earliest mention I have been a[illegible] of the sulphocarbolates as remedial agen[illegible] som, in the *Practitioner*, iii, 5-13 1869 Pap[illegible] him upon these salts also appear in the *British Medical Journal* in 1870 and in the Transactions of the Obstetrical Society of London, 1870-71 Sansom claimed that the sulphocarbolates were beneficial in phthisis typhoid fever and the eruptive fevers especially scarlatina for which he considered them specific

Subsequently papers upon these salts have been contributed by Q C Smith (*Nashville Journal of Med and Sur*, 1878) D Cerna (*Philadelphia Med Times*, 1879-80) Withers (*Dublin Jour of Med Sciences*, 1880), H P Farnham *Medical Record*, xxiii, 8, 1883), and F Vigier (*Bull et Mem Soc de Thera* 1884) Since the latter date there have been few papers listed under this title but every year sees an increasing number of references to the sulphocarbolates in the treatment of various affections

Leading manufacturing chemists furnish the carbolates of zinc, soda, lime potash and ammonia The sulphocarbolate of zinc, $Zn(SO_3C_6H_4OH)8H_2O$. is prepared by decomposing barium sulphocarbolate by zinc sulphate filtering off the barium sulphate and evaporating It forms beautiful white crystals when pure It is soluble in twice its weight of water or of alcohol and has no acid reaction The aqueous solution becomes violet on the addition of ferric chlorid should yield but a slight turbidity with barium nitrate is unaffected by ammonium oxalate or by sulphuric acid, and after precipitation by an excess of ammonium sulphid the filtrate on evaporation and ignition should yield no residue Heated to redness it yields 14 6 per cent of zinc oxid

My attention was attracted to the value of zinc sulphocarbolate in 1881, by Dr C L Mitchell who found it of much merit as a local application The first use I made of it was in the various forms of summer diarrhea, especially in cholera infantum In this affection I had noted the coldness of the extremities with heat of the forehead and the epigastrium, contracted pupils and small rapid pulse, with profound depression of the vital forces Precisely similar conditions are manifested in nasal diphtheria, excepting the epigastric heat and yet all these subside promptly when the nasal passages have been thoroughly cleansed and the absorption of toxins generated in the nasal passages has stopped The radical and immediate change for the better following such a cleansing by hydrogen dioxid solution had made a strong impression upon me, and when I noted the same aggregation of symptoms in cholera infantum, it was obvious that the cause was here also a toxin absorption, and that the long sought remedy was to be found in the antiseptic group

The first experiments were made with much difficulty The sulphocarbolate was generally so impure that half a grain excited local irritation and vomiting But when the chemically pure salts were obtained it was found that a child in the second summer could take from one-half to one grain every half hour with impunity, and with this dosage the method at once gave evidence of its value So remarkable has been the change effected by this remedy that it is now more than fifteen years since I have had a child die of cholera infantum, and I am convinced that the circumstances must be rare in which a child properly fed, with proper attention to the sanitary condition of the premises, and treated with the sulphocarbolate of zinc, will yet die of cholera infantum

From this was readily deduced the employment of the same remedy in all other affections of the alimentary canal attended with decomposition or fermentation, as evidenced by fetid or unhealthy stools, and the symptoms now known to be due to autotoxemia from fecal absorption The importance of this principle in the genesis of symptoms manifested in the nervous, circulatory or respiratory system, or in any other part of the body, is beginning to be realized, and would probably degenerate into a "fad," if such enthusiastic adoption ever occurred to a truth But it is only such discoveries as Perkins' tractors, Bergeon's gas inflations, and tuberculin, that receive the instant and unanimous approval of the public Truths, like vaccination and intestinal sepsis, must fight their way to acceptance

The next trial of the sulphocarbolates was in typhoid fever It requires, on an average, forty grains daily to render the stools of a typhoid patient odorless, but in some instances it has required 120 grains daily This amount is easily taken and does not irritate, if a pure salt is employed As a rule, I prefer to give it in powder, with a few grains of bismuth subnitrate, or in the pills made by the Upjohn process When the stools have become inodorous, the following alteration has occurred in the condition of the patient The diarrhea, tympanites, pain, tenderness, distention and gurgling in the abdomen have ceased, the aching of the head and the muscles, nocturnal delirium and ataxic symptoms have disappeared, the tongue has become moist and clean, the appetite has returned, the mind is clearer, and the temperature has fallen from one to two degrees In fact, the case has been reduced to the category of the mild form, the temperature falling below 103 degrees, the point at which advocates of the Brand method employ cold baths Many cases are aborted, and of those in which the physician is called so early that a diagnosis is not sure except by bacteriologic methods, but where the conviction is that we are dealing with the initial stage of typhoid, nearly every case is stopped within four days If, as I believe, the action of zinc sulphocarbolate is limited to the alimentary canal, the symptoms relieved by the administration of this drug are fairly to be attributed to absorption of toxins from the bowels, and the attack is reduced to the direct effects of such bacteria as have migrated beyond the alimentary canal before the drug is given

These effects are as uniform as those of any drug given as medicine they have been noted in numerous cases, without a single exception The proof is so easy and so complete that it only remains to explain how these effects are produced It seems evident that the zinc is not a germicide, that it acts by preventing the multiplication and functioning of micro-organisms, rather than by directly destroying them Indeed, it seems doubtful if any germicide can be introduced into the alimentary canal in sufficient strength to kill bacteria and yet not injure patient But the bile does not kill spores, and the absence of the bile occasions a large part of the symptomatology of all febrile diseases Fever checks the secretion of bile and this, with the increased heat and lowered vitality favors the action of micro-organisms in the whole alimentary canal The food, not properly digested, also decomposes more readily than in health, and this adds another element It follows, then, that in every febrile affection intestinal sepsis and autotoxemia are necessarily present and furnish a share of the symptomatology Hence the use of the sulphocarbolate is indicated in all fevers, not alone those that have their focus of operations in the bowels, like typhoid In pneumonia for instance, a reduction of the temperature and a corresponding amelioration of the symptoms follow the sulphocarbolate antisepsis, and this method may be prophylactic also, as it is known that the pneumonia is especially fatal if vomiting and diarrhea complicate it

This brings us to the latest development of sulphocarbolate therapy—its use in tubercular phthisis As the salt had reduced the temperature so certainly in all other forms of febrile disease, I concluded to give it in a case of pulmonary tuberculosis, with countless bacilli, high fever—104 degrees and over—and the nausea, anorexia, indigestion and diarrhea usual in such severe cases The patient improved at once, the fever dropping to 100 or 101 degrees, and the gastro intestinal symptoms completely disappearing, leaving the patient with the appetite and digestion of a plowboy As other remedies were employed, I can not credit the cure, in this case, to the sulphocarbolate alone, but as Dickson used to say that we could cure consumption when we learned to control the digestive difficulties, I am sure the sulphocarbolate contributed largely

It may be asked Since the sepsis and consequent toxemia are largely due to the diminution of the biliary secretion, why not restore it? Our fathers relied on calomel, and by its help flooded the bowel with nature's own antiseptic But there are *a priori* objections to this Nature sees fit to reduce to a minimum the action of the liver in all febrile diseases We do not know the reason for this, any more than we knew the importance of the thyroid gland a dozen years ago, but it is the part of wisdom not to interfere with the course of nature unless it is unavoidable, and especially when we do not comprehend her processes Since we do not know why the activity of the liver is reduced during fever, we had best let it alone, but we know very well the effects of intestinal sepsis, and hence, we interfere to prevent them Besides, the results of actual trial have shown that we can accomplish our object far more effectually, safely and pleasantly by the exhibition of the sulphocarbolates than by the use of cholagogues

As to the choice between the sulphocarbolates and other antiseptics, there is this to say the sulphocarbolates are extremely soluble Bouchard prefers naphthols on account of their comparative insolubility, believing that soluble salts leave the intestinal canal too soon to render it aseptic in its entire course But the action is strictly chemic, and he fails to inform us how a chemic antisepsis is to be secured without solution of the reagent It appears probable that the good effects of the naphthols are really due to the [illegible] that is dissolved Besides, in numer- [illegible] the h[illegible] [illegible]rance of the [illegible]hols [illegible] [illegible]e stool [illegible]d

Salol breaks up into salicylic and carbolic acids and in full doses is apt to produce hemoglobinuria The same objection holds good against all the carbolic derivatives, except the sulphocarbolates I have given these salts to many persons and never saw nor heard of a case of hemoglobinuria The iodic antiseptics occasionally cause iodism, even in small doses Eczematous individuals especially appear to possess the power of setting free iodin from iodoform, europhen, etc The biniodid of mercury has been strenuously advocated by Illingsworth, and the action of copper arsenite upon the duodenum demonstrated by Aulde, while mercury bichlorid has also its advocates But the highly toxic character of these and similar antiseptics confines their use within narrow limits The volatile oils, various chlorin preparations, sulphurous acid, hydrogen dioxid and potassium permanganate, are among the other antiseptics that have been urged for internal use, but the objections to all, for indiscriminate prescription, are obvious It is, however, notable that good effects have been obtained from many agents of this class The principle is of wider applicability than that of any agent in the group

The sulphocarbolates labor under the disadvantages of being common and cheap—they cost about 60 cents a pound, as against a dollar an ounce for the proprietary articles, they can be prepared by any manufacturing chemist, and have no commercial interests to push them, and finally, they have no name great in the councils of medicine to back them up Deprived of the potent support of printers' ink, they rest solely upon their merit, without puffing, and on this basis have won a place in the armamentaria of thousands of physicians to whom utility is the only incentive to the employment of medicine

I have only spoken of the sulphocarbolate of zinc, but there are two other salts of this group that deserve notice Sodium sulphocarbolate may be given in doses of 20 to 30 grains The bodies of animals to which it has been given resist putrefaction for a ong time It has been recommended as a remedy or vomiting, for fermentative affections, and for eudo-membranous diseases, with gangrene or neosis, such as scarlatina and diphtheria Several eports appeared some years ago as to its value in these affections J W White pronounced it antacid, stringent, sedative, styptic, antiseptic and disinfectnt The sulphocarbolate of lime is also quite free from local irritant effects, and somewhat more antiseptic than the soda salt Of the three, I prefer the zinc when a strong and certain effect is required, as in cholera infantum, typhoid fever, or marked intestinal sepsis the soda sulphocarbolate, when the stomach is irritable, for milder forms of sepsis, or when an antacid is also indicated, the calcium sulphocarbolate for strumous or tubercular cases, or any other in which the reconstructive effects of lime are required, or where other lime-salts are indicated These three sulphocarbolates have been combined in tablets, and for indeterminate cases these have fulfilled every requirement, being effective and non-irritant

---

Transplantation of Stenson's Duct —In a case of recurring fistula, Goris opened up the duct from its starting point to its termination in the mouth, which he detached from all adherences, excising all the surrounding connective tissue He then fastened it with a couple of stitches behind its natural location, endermic suture of the cutaneous incision Recovery was prompt and by first intention —*Presse Méd*, September 3

INCOMPATIBLES

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY E A RUDDIMAN, PH M, M D
SCHOOL OF PHARMACY VANDERBILT UNIVERSITY NASHVILLE, TENN

To the practitioner, as well as to the patient and pharmacist, the prescription is an object of importance Upon it the welfare of each one of these more or less depends If it fails the mission of the physician and of the pharmacist fails Heretofore, schools and colleges of medicine have not laid sufficient stress upon the combining of medicines Within the last few years there has been a change for the better, and the graduates at the present time know more than did the graduates of a few years ago However, even yet it is the exception rather than the rule to meet a young man who knows more than a little about writing prescriptions, and he may consider himself fortunate if he knows more than a little about the individual ingredients of the prescription It is not his fault, but that of his professors, that he is not better prepared for this part of his work The student, while in college, should be so thoroughly drilled in combining the best preparations in the best way that it will come naturally to him to write a correct prescription from the start

The mere writing of a list of substances is not all that is necessary for a good prescription In the first place, the physician must have diagnosed the case properly, and when he has determined what drugs will probably meet with the best success, he must choose what individual preparations will go together with the best result It is in choosing the preparations that he so frequently fails Let me illustrate with a single example Suppose it is desirable to give tincture of chlorid of iron, strychnin sulphate, some preparation of arsenic and some preparation of cinchona, with the syrup of orange as a vehicle Naturally the physician would choose Fowler's solution and a tincture of cinchona In filling such a prescription there is danger of the alkali in the Fowler's solution precipitating the strychnin, the alkaloids in the cinchona and also the iron, and the ferric hydrate thus precipitated would combine with the arsenic to form an insoluble compound And again, the tannin in the cinchona would combine with the iron, forming the black, inky, ferric tannate In place of Fowler's solution the solution of arsenous acid should be used, it having the same physiologic effect and being of the same strength, but acid in reaction In place of the tincture of cinchona there should be used quinin sulphate, or some such preparation as the National Formulary compound elixir of quinin, or the detannated tincture of cinchona

In writing a prescription the physician must bring into use his knowledge of materia medica, therapeutic, physics, chemistry and pharmacy No single one of these divisions will give him the requisite information, he must know therapeutics, in order to avoid physiologic incompatibility, he must know pharmacy and the physical properties of drugs in order to avoid pharmaceutic incompatibility, and he must know chemistry to avoid chemic incompatibility

Perhaps the two great stumbling blocks to the physician in this line are pharmacy and chemistry Without a knowledge of both he is at sea His only safeguard is to prescribe one or at most two substances together This is no doubt desirable sometimes, although not always I have had medical students ask me what good it will do them to spend so much time on these subjects My answer has been to study assiduously now and they will know the use hereafter That actual harm has sometimes come to patients from taking incompatible prescriptions is a fact beyond dispute, and we have the watchful pharmacist to thank that there are not more such cases And even though no ill effect may result from an incompatible mixture, frequently no good comes from it, and we blame our books, the drugs, and the pharmacists for not getting the results that we expected, when our ignorance of pharmacy and chemistry is the cause No doubt we have all had our nerves somewhat rudely shaken by being told that a pet combination of ours is rendered either dangerous or inert by chemic reaction

A few general rules can be given in regard to what will form incompatible mixtures, but the majority of cases must be learned as isolated facts These general rules are given in nearly every book on materia medica as fully as I could give them in such a paper as this Many times we see the bare statement that two substances are incompatible, and to know this and nothing more is unsatisfactory and frequently useless Because chemic reaction takes place, it does not necessarily follow that the mixture should not be prescribed, or that the products formed will not have a similar physiologic action We should know what changes occur and what compounds are produced, otherwise how can we tell what the effects will be? Will the action of a mixture of spirit of nitrous ether and potassium iodid be the same as either or both taken separately? Or is the effect of an application of a mixture of lead water and laudanum similar to the effect of these preparations when applied separately? Are the effects of the green isonitroso-antipyrin what are wanted when antipyrin is prescribed with spirit of nitrous ether? Then let us not denounce the pharmacist as having worthless preparations, or accuse the physiologist of having made mistakes in regard to the actions of medicines, until we know that the failure is not due to incompatibility

The number of incompatibilities is one which will increase rather than decrease with time With the advent of nearly every new remedy the number is increased Particularly is this true of the new synthetic compounds with which the country has been flooded for the past few years Physiologic incompatibility does not occur in a prescription nearly as frequently as chemic or pharmaceutic This is not because the physician has given this part of the subject more consideration, but due partly, at least, to the fact that he is not generally tempted to put into the same prescription remedies that are antagonistic

To become convinced that the subject of incompatibility is one which has not received the attention which its importance demands, we have but to glance over the appended prescriptions, which are a few of those to be found in standard works on medicine and therapeutics When our best authorities fall into such errors, it is not to be wondered at that the beginner should make many mistakes Those of us who come in contact with students in medical colleges should give more instruction along this line It is one of the weak points in the curriculum of many colleges A neglect of this subject by a physician means a continual menace to the life of his patient

℞ Collodii,
Spt ammoniæ,
Tinct iodi, āā part aeq
Sig —Paint over part with a camel's hair brush
—Potter's Mat Med and Ther , 6th ed , p 716

In this prescription the iodin is changed chiefly to ammonium iodid with a little ammonium iodate Did the prescriber know this and did he wish to get the action of these instead of the action of iodin?

℞	Hydrarg iodid viridis	gr 3/4	0485
	Potass chlorat	gr iij	1943
	Potass iodid	gr 3/4	0485
	Chocolate, q s		

M —Ft in tabellum No 1
—Hare's System of Prac and Ther , Vol ii, p 160

In the presence of moisture the potasium iodid reacts with the mercurous iodid, causing the formation of metallic mercury and the much more active mercuric iodid (the red iodid of mercury) The potassium chlorate in the presence of a mineral acid, as the hydrochloric acid of the gastric juice, causes the iodin to be set free

℞	Hydrarg chlor corrosiv	gr ss		0324
	Potassii iodidi	℥ ss	15	555
	Decocti cinchonæ	fl℥ viij	236	195

S —Fl℥j ter die post cibum
—Farquharson's Ther and Mat Med , p 334

The potassium iodid combines with the corrosive sublimate and forms first the red iodid of mercury, and then combines with this to form the soluble double compound—potassium mercuric iodid This double compound combines with the alkaloids of cinchona in the decoction and forms a precipitate The danger in this prescription lies in the mercury being thrown out of solution Did the physician realize that it is possible for the patient thus to take most of the mercury at one dose?

℞	Sodii sulphitis	ʒ ij	7	775
	Sp ætheris nit	℥ ss	15	555
	Liq ammon acet	℥ iij	93	309
	Aq dist	℥ ij	62	206

Mix —Sig Teaspoonful every two hours
—Hare, Vol ii, p 391

The spirit of nitrous ether is decomposed, giving off the gas, nitric oxid, and part of the sodium sulphite is changed to sodium sulphate

℞	Hydrargyri	gr 1/8	008
	Iodini	gr 1/2	0323
	Ac tannici	gr [illegible]	0388
	Glycerini	m xv	0615

M
—Hare, Vol ii, p 125

The iodin will change the mercury to mercuric iodid The tannic acid will change part of the iodin, with the formation of hydriodic acid, which will further combine with the red iodid of mercury

R	Tinct. ferri chloridi	ʒ ij	7,775
	Acidi sulphurosi	ʒ j	3 887
	Potas chlorat	ʒ j	3,887
	Glycerinæ	℥ ss	15,555
	Aq calcis , q s ad	℥ iij	93'309

Misce Dose one teaspoonful every hour to two hours for a child of three years
—Smith's Diseases of Children, 6th ed , p 321

On adding the sulphurous acid to the tincture of iron the mixture becomes of a much darker color at first and then nearly colorless The glycerin may now be added and then the potassium chlorate dissolved in the water There is barely a sufficient amount of water to dissolve the chlorate, and after mixing with the ingredients some of the salt is thrown out of solution by the alcohol in the tincture The possible reactions are as follows 1, Between the ferric chlorid and sulphurous acid, forming ferric sulphite and hydrochloric acid, 2, the ferric sulphite thus formed changes to ferrous sulphate, 3, between the potassium chlorate and the hydrochloric acid in the tincture, forming chlorin, 4, between this chlorin and the ferrous sulphate, forming ferric sulphate and hydrochloric acid, 5, between the chlorin and the sulphurous acid, forming sulphuric and hydrochloric acids, 6, between the chlorin and the glycerin, 7, between the potassium chlorate and the sulphurous acid, forming potassium sulphate and hydrochloric acid, 8, between the ferric chlorid and the lime water, forming ferric hydrate and calcium chlorid, 9, between the sulphurous acid and the lime water, forming calcium sulphite

Did the prescriber determine beforehand what products would be formed and that these were the compounds whose actions were wanted?

GLANDULAR EXTRACT

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10 1898

BY ISAAC OTT, M D
PROFESSOR OF PHYSIOLOGY MEDICO-CHIRURGICAL COLLEGE,
PHILADELPHIA
EASTON PA

Glandular physiology in its widespread ramifications has revolutionized many parts of physiology and pathology It is only in its infancy and its maze of metabolic changes holds many facts to be discovered The secretion of the ductless glands opens up new avenues of investigation, which will enrich the science of physiology and the practical application of these facts in therapeutics We have a silent and hitherto unsuspected secretion going on which plays a most important and unknown part in our economy Very potent remedies are the ductless glands, where but a few thousandths of a grain of a gland like the pituitary greatly elevates the arterial tension I have made over one hundred experiments upon the lower animals with the various extracts obtained from Armour & Co of Chicago The experiments upon the reflexes were made upon frogs, those on pulse pressure, respiration and temperature upon rabbits The results were as follows

Adrenals—The adrenals caused an increase of reflex activity, which was as fugitive as the rise in arterial tension It also depressed the pulse rate The rise of blood-pressure was due to an action upon the walls of the artery It decreased the rate of respiration

Pituitary—It depressed reflex activity for a short period, reduced the heart-beat and elevated arterial tension This elevation was due to an action upon the arterial wall The respiration rate was increased by it

Spleen—The spleen diminished reflex action It also depressed the pulse and temporarily the arterial tension Afterward the arterial tension increased It had an unusual action in increasing the peristaltic movements of the intestine The respiratory movements were also increased

Iodothyrin—It had no general action upon frogs Upon the pulse-rate and arterial tension it had no marked effect, except a slight increase of pulse-rate at times It increased the respiratory movements

Thyroid—In the frog it depresses the reflexes It lowers the blood-pressure and heart-beat It accelerates the respiratory movements

Pancreas—It decreased the pulse and arterial tension

Testicle—It lowered the pulse and slightly increased the arterial tension

Upon the temperature nearly all these agents caused an elevation

---

THE WOUNDED OF THE PORTO RICAN CAMPAIGN

BY N SENN, LIEUT COL U S V
CHIEF OF THE OPERATING STAFF WITH THE ARMY IN THE FIELD

The Cuban and Porto Rican invasions have confirmed the experience of the past in showing that the greatest horrors of war are caused by disease and its consequences rather than the implements of destruction If the battle-grounds are in the extreme north or south, climate enters as an important factor in decimating the ranks and in increasing the sufferings of the contending armies A war of invasion requires more preparation, foresight and forethought on the part of those who plan and conduct the campaign than one of defense, a fact we have been painfully made aware of during the last two months The more remote the seat of conflict, the more difficult the task of providing food and clothing for the army, and the more serious becomes the problem of properly caring for the sick and wounded, and the greater becomes the difficulty in returning the survivors to their homes Nostalgia, a very common affection among unseasoned troops, becomes more prevalent in proportion to the distance between home and the seat of war, as we had abundant opportunities to observe during the late war The depressing effect of this common ailment has a decided influence in increasing the rate of mortality of the sick and wounded, and in impairing the effectiveness of the fighting line Nostalgia is a contagious disease, not in the sense we use the word contagion ordinarily, but when once established in camp it increases rapidly by suggestion The onset and spread of this common ailment of camp life are promoted by interruptions of the mail service, the only medium of communication between the soldier in the field and his distant home Among the many sins of omission of those in charge of the management of the late war was a glaring neglect to provide for the much-needed and anxiously looked for mail facilities If those who have the management of this branch of the government service in charge could be made to understand what an occasional letter will do in keeping up the spirit of the citizen soldier, nostalgia would have been less prevalent and its effects less disastrous during the late campaign From the time I left Fortress Monroe for Cuba, July 3, and until I arrived in New York from Porto Rico, August 19, I received only two letters of the probable two hundred sent to me during this time In summing up the casualties of the war just ended, it is safe to make the statement that the number of killed and the number of deaths resulting from the immediate effects of wounds will not exceed 280 The number of wounded will in all probability reach 1425 The number of deaths from malaria, dysentery, yellow fever and typhoid can not be estimated at this time, as these diseases are still prevailing and will claim many victims before the troops are recalled The loss of life and the suffering as well as disability, as a claim for pension, caused by disease and the effects of climate will exceed by far those caused by Spanish bullets During the Porto Rican campaign no pitched battle was fought The force of the enemy in all of the skirmishes was small and in ambush Only a few were killed and not more than forty were wounded Among the wounded, bone injuries were rare, many of the wounds slight All of these cases tend to confirm previous observations to the effect that the small caliber bullet of the Mauser rifle, the one used exclusively by the Spaniards, causes wounds of the soft parts, which if left alone under the first dressing, will heal by primary intention in the course of a week or two, unless complicated by serious visceral injuries All of these cases corroborate the statement previously made that the small caliber bullet does not infect the wound and that it seldom carries with it into the tissues clothing or other infectious substances This observation, so abundantly supported by substantial facts, is an extremely important one for future field service, as it must satisfy the military surgeons that such wounds will heal promptly if left alone under the first-aid antiseptic dressing On the other hand, I have seen the evil consequences following meddlesome surgery in the form of unnecessary probing Such wounds are very susceptible to secondary infection caused by the use of the probe For the purpose of again calling attention to the humane nature of the modern weapon, and with a view of showing how rapidly wounds inflicted with the small caliber bullet will heal under the most conservative treatment, I will report briefly the nature of the wounds and the results of those wounded in the Porto Rican war

Case 1 —Lieut J C Byron, Troop F, Eighth Cavalry, wounded in the skirmish near Mayaguez, August 10 The bullet passed through the foot from side to side on the dorsal aspect, making a groove on the upper surface of the second and third metatarsal bones without fracturing them Healing by primary intention under the first dressing He was in the saddle when injured

Case 2 —Lieut John Haines, Battery F, Third Artillery, was wounded in the attack on Aibonito, August 13, and is probably the last man shot by the Spaniards during the invasion of Porto Rico He was in the advance of the line, with his battery planted on a high hill in full view of the enemy After firing the number of shots ordered, the gun was turned, and at this moment a bullet struck him in the left lumbar region, postaxillary line, and escaped about the sixth intercostal space, anterior axillary line on the same side No indications of bone injury or penetration of the chest The wounds were dressed in the field and healed by primary intention He was conveyed in an ambulance from the front to Ponce a distance of twenty miles, and transferred to the hospital ship *Relief* At no time has he suffered much from pain or even a sense of discomfort which could be referred to the wound The patient must have been in a stooping position the moment the injury was received

Case 3 —Lieut T H Hunter, Battery B, Fifth Artillery, was accidentally shot by one of his own men by a Krag Jorgensen bullet, which entered the right side of the ilium, passed downward and backward, emerging from the gluteal region on the same side below the ramus of the ischium The course of the bullet excluded bone injury in this case Notwithstanding the length and depth of the tubular wound it healed rapidly by primary intention The indications are that the patient will recover without any functional impairment of the parts implicated in the injury

Case 4 —William H Walcutt Company E, Fourth Ohio Infantry, was wounded in the skirmish near Guayamo, August 8 The bullet entered the plantar surface of the left foot between the first and second metatarsal bones, at the junction of the middle with the distal thirds and escaped from the dorsal side, at a point a little nearer the distal side From the course of the bullet it is clear that he was running in a direction opposite to the enemy when the shot was fired The wounds were healed a week after the injury was received

Case 5 —William J Edgington, Company A, Fourth Ohio Infantry, was wounded during an engagement, August 8 The wound of entrance was at a point two inches to the left of the median line on a level with the sacro coccygeal joint, the wound of exit at the base of the opposite thigh over its inner and middle aspect, directly over the adductor muscles No evidence of any serious visceral injury of any of the pelvic organs The temperature remained normal, the wounds healed by primary intention, and when I examined the patient in the hospital at Guayamo, five days after the injury was inflicted, the patient was free from pain and able to leave his cot without assistance The course of this bullet explains the position of the patient at the time the bullet reached its unwilling moving mark

Case 6 —Noble W Horlocker, Company C, Fourth Ohio Infantry, was wounded in the same skirmish The bullet entered one inch in front of the right malleolus and escaped two and three fourth inches below and a little behind the external malleolus Although the bullet must have passed through the ankle joint and the astragalus, the injury was followed by very little pain, except on moving the ankle joint, and no indication of infection had set in five days after the injury was received It is reasonable to expect that the wounds will heal by primary intention, and that the patient will recover with a useful movable ankle joint

Case 7 —Stewart J Mercer, Company E, Fourth Ohio Infantry, was wounded August 5, in a skirmish on the way from Arroya to Guayamo The bullet made a flesh wound over the inner margin of the left patella, and healed by primary intention in a few days

Case 8 —Samuel T Jones, Company C, Fourth Ohio Infantry, received a wound above the right patella, August 8 Wounds of entrance and exit one inch apart Primary healing under the first dressing

Case 9 —Edward O Thompson, Corporal Company K, Fourth Ohio Infantry, was wounded near Guayamo, August 8 The bullet entered the forearm two thirds of an inch above the wrist joint, on radial side, and after passing through the soft tissue in front of the bones, emerged from the inner aspect of the forearm just above the wrist joint Wound healed by primary intention under the first dressing

Case 10 —Harry Lee Haynes, Company C, Fourth Ohio Infantry, was lying down in a ditch at the time he was wounded, August 8 The bullet struck the arm two inches above the insertion of the deltoid muscle and emerged over the sterno clavicular articulation on the same side A third wound was found on a line with the course of the emerging bullet one inch below the mastoid process and in the direction of the sterno cleido mastoid muscle A fourth wound, an inch and a half in length, one quarter of an inch in depth and an inch in width, was found on the dorsum of the right fore arm an inch above the elbow joint All the wounds healed rapidly, caused but little suffering, and the patient was in a fair way to recovery when seen a few days after he was wounded

Case 11 —Clarence W Riffer, Company A, Fourth Ohio Infantry, was wounded August 8 The bullet entered the right thigh at a point five inches above the knee joint and about the middle of the external surface passed through the soft tissues making its exit three inches to the left of the point of entrance It re entered the left thigh at a point two and a half inches above the knee joint, and an inch and a half to the right of the posterior median line and emerged on the oposite side an inch and a half above the knee joint Both flesh wounds deep and long as they were healed primarily without suppuration

Case 12 —John O Cordner, Company C, Fourth Ohio Infantry was wounded August 5 The bullet made a flesh wound at the lower border of the patella, the wounds of entrance and exit being separated by a space an inch and a half in length Primary healing under first dressing

Case 13 —William Rossiter, Company G, Eleventh U S Infantry was wounded in the skirmish near Mayaguez August 10 He was shot through the inferior maxilla The bullet entered just below the margin of the bone on the right side about an inch in front of the angle and emerged over the angle of the bone on the opposite side, perforating the soft tissue of the neck in a transverse direction The bullet appears to have passed through the bone without fracturing it The only pain the patient complains of is produced when he undertakes to masticate food Wounds of entrance and exit healed in a few days by primary intention

Case 14 —Amos Wilkie Eleventh U S Infantry was on the march when wounded near Mayaguez, August 10 The bullet entered the right lumbar region just above the crest of the ilium, mid axillary line, and emerged about two inches to the left of the spine and four inches above the left sacro-iliac synchondrosis No indications of intra abdominal complications He suffered considerable from cramping pains, which he attributes to cold and fever which he contracted by exposure to rain A week after the injury was received, when the patient was an inmate of the Hospital Ship *Relief*, his condition warranted the hope of an early and complete recovery

Case 15 —Harry C Errick, Company C, Eleventh U S Infantry, was wounded August 10, in a charge on the enemy in ambush Wound of entrance in left leg over the outer aspect of the middle third, the bullet passed downward and inward and emerged about five inches above the inner malleolus Hemorrhage slight, no fracture Wound healing rapidly under first dressing

Case 16 —William H Wheeler, Company A, Eleventh U S Infantry, was wounded August 10, near Mayaguez, when in a standing position with his side in the direction of the enemy, his gun down, ready to reload The bullet struck the tenth intercostal space, left side, in the post axillary line and made its exit about four inches from the spine in the lumbar region close to the margin of the last rib No serious complications followed the injury, and at the present time, August 14, the patient is improving rapidly

Case 17 —George Curtis, Company D, Light Battery, Fifth Artillery, received a wound of the chest August 10, being in his saddle at the time The bullet passed through the chest from the second left intercostal space in front to the middle of the outer border of the scapula on the same side No hemoptysis or any other serious symptoms indicating the existence of the visceral wound of the lung The only thing he complains of is a sense of numbness in the left arm Primary union of both wounds

Case 18 —Joseph P Ryan, Corporal Company A, Eleventh U S Infantry, was wounded August 10 The bullet passed through the ankle joint Wound of entrance over the internal malleolus of left leg, wound of exit two inches below the outer malleolus No infection or signs of synovitis Wounds healing by primary intention

Case 19 —Samuel Copp, Company A, Eleventh U S Infantry, received a scalp wound, August 10, while he was lying on his abdomen on the summit of a hill Wounds of entrance and exit about two inches apart, healed under the first dressing He is suffering from a contusion of his abdomen he sustained by falling over an embankment during the same skirmish

Case 20 —Arthur Sparks, Company C, Eleventh U S Infantry, received a wound of the lower third of the left thigh, August 10 Wound of entrance on external anterior aspect of thigh about five inches above patella The bullet passed directly backward and came out on the opposite side on the same level without injuring the femur Healing by primary intention

Case 21 —George W Whitlock, Company C, Sixteenth Pennsylvania Infantry, was in a kneeling position when wounded near Guayamo, August 9 The bullet entered the thigh near the perineum, over the adductor magnus muscle, passed in an outward and backward course and emerged from the gluteal region near or over the sciatic foramen Hemorrhage slight Paralysis of the foot and lower part of the leg points to injury of the sciatic nerve Healing of wound without complications

Case 22 —James Drummond, Company K, Sixteenth Massachusetts Infantry, was wounded near Guayamo, August 9 The bullet entered the neck on the left side, behind the sternocleido mastoid muscle, two inches below the mastoid process Wound of exit on the opposite side in front of the trapezius muscle No immediate or remote complications Wound healed by primary intention Patient has suffered from slight attack of malarial fever

Case 23 —Paul J Mytzkie, Company D, Eleventh U S Infantry, was wounded in the skirmish near Mayaguez, August 10 The bullet made a flesh wound three inches above the external malleolus, which healed in a few days by primary intention under the first dressing

Case 24 —Daniel J Graves, Company M, Eleventh U S Infantry, received a gunshot wound of the thigh near Mayaguez August 10 The bullet passed through the thigh in an antero posterior direction, fracturing the femur at the junction of the middle with the lower third A week after the injury the patient was in excellent condition, the wounds remaining aseptic and healing rapidly

Case 25 —Theodore H Newbold, Company I, Sixteenth Pennsylvania Infantry, was shot while retreating during the skirmish near Guayamo, August 9 The bullet entered the right arm above the olecranon process and emerged from the extensor side of the forearm between the radius and the ulna The olecranon process was broken off The X ray reveals the presence of a fragment of the bullet, or its mantel, lodged in the wound Aseptic healing of the wound

Case 26 —Clyde C Frank, Company C, Sixteenth Pennsylvania Infantry, was injured near Guayamo, August 9 The bullet entered the inner surface of the middle of the right thigh, passed upward and backward, and in grazing the femur made a groove without fracturing the bone, emerging from the external and posterior aspect of the thigh Both wounds healed by primary intention In making a skiagraphic examination of the seat of injury a fragment of the bullet was discovered in the groove The piece of lead, as well as a few loose fragments of bone, were removed August 17 by enlarging the wounds of entrance and exit Operation by Dr Shultze

Case 27 —John L Johnson, Company D, Eleventh U S Infantry, received a gunshot injury near Mayaguez, August 10 The bullet passed in an antero posterior direction through the middle third of the left leg, going through the space between the tibia and fibula Hemorrhage slight Healing by primary intention

Case 28 —Samuel G Frye, Company D, Fifth Artillery, was injured by a deflected bullet, as he stood by his cannon, near Mayaguez, August 10 The bullet passed through the soft tissues in the right anterior axillary fold without doing any further damage The wound healed by primary intention

Case 29 —Henry Gerrick, Company E, Eleventh U S Infantry, received a superficial wound over the pronator muscles, near Mayaguez, August 10 The wound healed promptly by granulation

Case 30 —John Browning, Corporal, Battery D, Fifth Artillery, was wounded near Mayaguez, August 10 The bullet passed transversely through the soft tissues of the right forearm on a level with the wrist, in front of the radius and ulna The bullet evidently cut the ulnar nerve and vein, as shown by the paralysis of the parts supplied by the nerve below the seat of the wound and the free venous hemorrhage which immediately followed the injury Healing by primary intention

The marked contrast in the results of the treatment of the wounded in Cuba and Porto Rico, I attribute entirely to the better preparations made for the last invasion, and not to any difference in the surgical skill of the medical officers The surgeons engaged in the Cuban war were men exceptionally well prepared for their profession, and performed their onerous task with energy and enthusiasm Ambulances were scarce, the fighting line far away from the base hospital, conditions which made it difficult to render timely and efficient first aid Another circumstance which had its influence in interfering with the prompt and effective first aid to the wounded in Cuba was the large number of men who fell in battle in three days The war in Cuba precipitated in a pitched battle, in Porto Rico it consisted in a number of skirmishes in which only a small number needed surgical attention In Porto Rico the rear of the different armies was supplied with an adequate number of ambulances and Hospital Corps men The first aid was rendered almost immediately after the wounds were received, after which the patients were conveyed to the hospital at once A sufficient number of medical officers were on hand during each engagement to take immediate and proper care of the wounded In most instances the wounds healed by primary intention under the first dressing The value and importance of early surgical attention, and the first-aid dressing, became apparent in comparing the condition of the wounds, a week after the injuries were received, during the Cuban and Porto Rican campaigns

---

Carcinoma of the Esophagus —Carcinoma of the esophagus can remain latent, that is, not cause any difficulty in swallowing nor in the passage of a sound, until death, if it extends lengthwise and does not invade the entire circumference Leichtenstein recently exhibited a number of preparations to the Cologne Medical Association in which a narrow, elastic groove had remained free from carcinomatous invasion to the last, allowing the ingestion of food, although the carcinoma had extended 9 cm perpendicularly —*Munich Med Woch*

COLPOPERINEORRHAPHY AND THE STRUCTURES INVOLVED

DEDICATED TO DR THOMAS ADDIS EMMET AND MR LAWSON TAIT IN RECOGNITION OF THEIR LABORS IN THE SURGERY OF THE PERINEUM

BY BYRON ROBINSON, B S, M D
CHICAGO ILL

Continued from page 860

The second step of the operation is to introduce the sutures of silkworm gut The two fingers are removed from the rectum and well cleaned The point of the handled needle is introduced at the upper angle of the wound (No 2 in Fig 21) without penetrating the skin or vaginal mucous membrane, carried along about one-half inch from the distal edge of the vaginal flap and made to emerge at the median raphe It is then threaded and drawn out The point of the needle is again introduced at the upper angle of the wound on the opposite side (No 4 in Fig 21), forced along the distal edge of the flap about one-half inch from the edge and made to emerge again on the median line It is threaded and drawn out This constitutes the first suture Generally three anterior sutures are introduced in the above manner To introduce the posterior sutures (three or four) the index finger should be placed in the rectum as a guide to avoid passing the needle too close to the rectal mucosa, endangering fistula The fistula may arise quickly or slowly If quickly an abscess will arise if slowly (two to four weeks) a fistula will arise and remain a longer or shorter time In one case a fistula persisted for three years The posterior sutures are introduced similar to the anterior However, they should be deeper and should thoroughly include the levator ani fascia superior and in [illegible] the enclosed levator ani muscle T[illegible] needle is passed into the edge of t[illegible] the skin, and pushed onward to the median line where the point emerges is threaded and drawn out It is again introduced on the opposite side and threaded in the middle In all cases requiring extensive dissection the needle should be passed through half of the wound only In the less extensive part of the wound the needle may pass through the whole wound at once Mr Tait employed three to five sutures We employ five to seven sutures

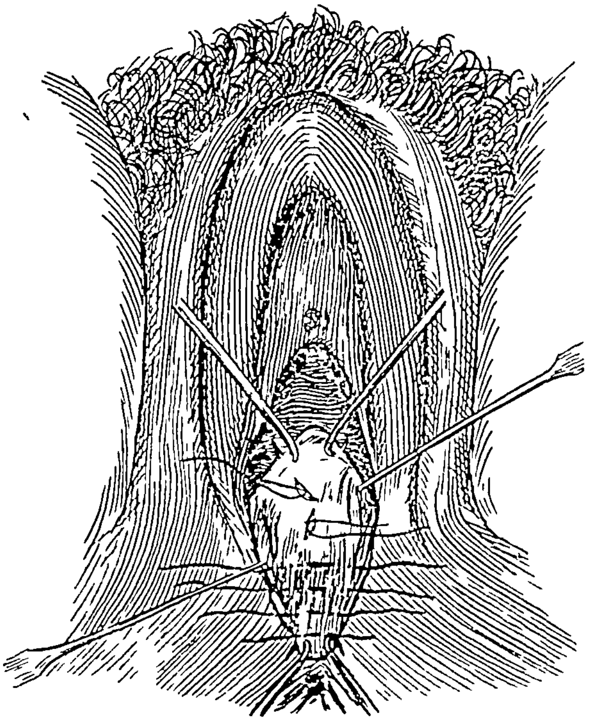

Fig 38 —(Author) A stage in progress of the flap-forming colpoperineorrhaphy Here the sutures appear as if the process had started at the anus but the safest and most practical method is to begin to introduce sutures and tie from the anterior end All sutures are threaded in the median line The needle may be thrust across the entire denuded field but one can make more perfect and deeper suturing by doing one half at a time

The third step is to tie the sutures of silkworm gut All the sutures are seized at the distal end by the left hand while the right hand pushes the tissues of the wound as far toward the loop of the sutures as possible This is a partial step, as it narrows and puckers the wound very much, so that when each individual suture is tied it assumes its final location The sutures should not be tied too tight, as they are apt to cut through considerable tissue After the sutures are tied, a linear gap of considerable width will exist in the median line, for the sutures do not penetrate the skin, and hence will not draw it in close coaptation Here some of the inexperienced will be tempted to place a few skin sutures to avoid the gaping of the wound Be sure not to do it, for they cause pain and may produce an abscess When the legs are placed together the edges of the wound will coapt The ends of the sutures should be left long and all tied into a single bundle The after treatment consists in applying no dressing or chemicals to the wound If there be considerable pain small hypodermic doses of morphin may be used for thirty six hours Most patients will require catheterizing, from trauma to the distal ends of the pubic nerves After forty-eight hours we begin to give t[illegible] quarts of a vaginal douche evening and morning The bowels should be moved on the third or fourth day by means of calomel [illegible] in small do[illegible] [illegible] [illegible] or thr[illegible] times) [illegible] MgSO4 Diet [illegible] nd [illegible] before [illegible]

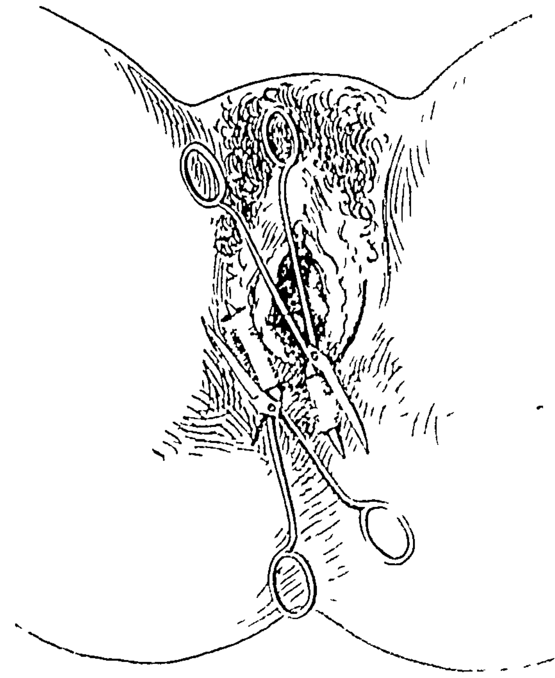

Fig 39 —(Robinson Holland) Method of formation of anterior and posterior flaps in the flap method of executing colpoperineorrhaphy

should be watched. If one becomes loose it should be removed. If none become loose or separate they may remain for three, four or even six weeks. Three weeks is soon enough to remove the sutures. The wound heals more firmly with the sutures in for four weeks or more. The sutures act like splints, holding the surfaces in fixed coaptation, avoiding motion, which interferes with perfect union. The sutures often give pain on removing, and it would perhaps be better in some neurotic cases to anesthetize the patient. However, I never practise it. Amateurs must be warned not to close the vulva unnaturally tight as it might disturb marital relations. The cuts in the article will show the steps in the technique.

THE EMMET OPERATION

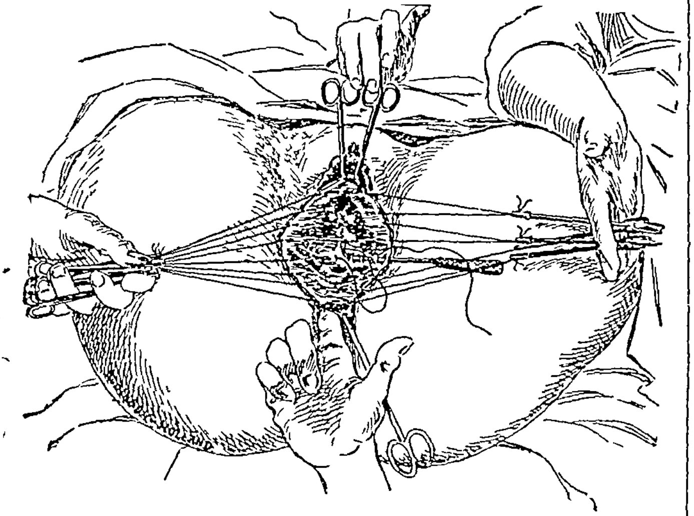

Fig. 40.—(Robinson Holland.) Method of introducing the sutures in he flap method of colpoperineorrhaphy. Note that the handled needle threaded in the median line. This cut was drawn from a photograph taken of a patient during the operation.

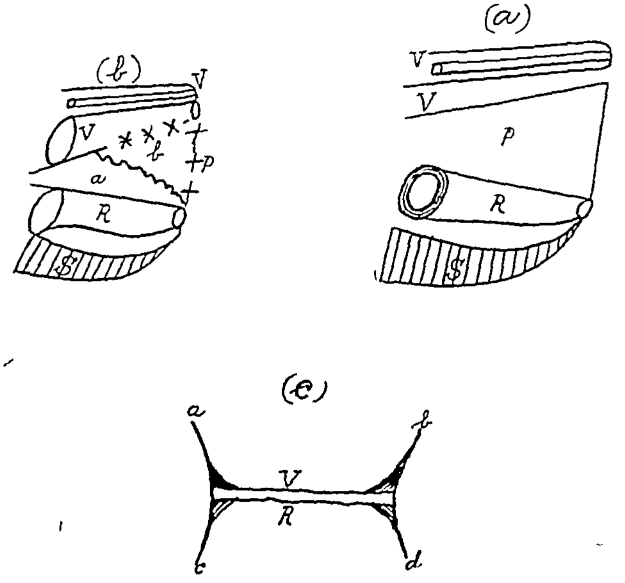

Fig. 41.—(Author.) Diagram of the plan of Tait's flap colpoperineorrhaphy. a. S. sacrum. R, rectum. P. intact perineal body. V, vagina with urethra above it. b. has had the torn perineal body, P, repaired by the six sutures marked by stars. c. shows the H shaped anterior cuts a. b. c, d. the posterior cuts. R. rectum. V. vagina.

This operation is in marked contrast to all previous ones for similar purposes, as union of the denuded labia was the first procedure. The *peculiarity* of Emmet's operation consists in denudation of the lower median posterior vaginal wall, bilateral denudation of triangular portions of the lateral sulci of the vagina, in the method of introducing the sutures, which are so arranged that on tying they lift the prolapsing parts toward the pubic arch, restoring anatomic structures, as the H-shape to the vagina and the normal curve of the vagina. The patient should be prepared for several days by cathartics and daily skin baths. The bowels should be evacuated by eight to twelve passages, so that no feces will be in the rectum while operating, nor for 24 to 36 hours after. Thorough salt rubbing of the skin not only stimulates the apparatus of the skin to the climax of secretion but reflexly stimulates the bowels and kidneys to active secretion. In short, place all secretory organs—skin, bowel and kidney—at their maximum activity for the operation. Place the anesthetized patient on the back, with an assistant holding each limb. With tenacula fixed to definite points of the vagina, as for example, one at the median crest of the rectocele, one tenaculum on each side of the vagina at the highest point of the triangle of denudation in the sulci and one on each side of the posterior vaginal wall at the junction with the skin and mucosa, one can mark the outline of the denudation with a scalpel. It is well, before denudation, to test whether the area is too large to insure coaptation of the wound without undue tension. The area defined by the tenacula is denuded by the operator cutting off long strips of vaginal mucosa with scissors curved on the flat. Others denude with the scalpel, rolling the denuded vaginal flap on a staff or on the fingers. With experience, large areas may be rapidly denuded. The area requiring denudation in the lateral sulci depends on the amount of slack in the posterior vaginal wall, for this operation has the special merit of narrowing the vaginal canal. With a typically relaxed vaginal outlet a large area of denudation will be required, and especially high in the right and left vaginal walls. The denudation should consist of the whole thickness of the vaginal wall. Continuous hot water irrigation over the denuded surface will check the hemorrhage. The operation is eminently a posterior colporrhaphy, and the success will depend on denudation in the lateral vaginal sulci, and not on the denudation of the so called perineum. In case the vaginal wall is very slack and thin it is well to extend the denudation deep into the bilateral subvaginal tissue in the vaginal sulci. Perfect denudation is a requisite, no islands of vaginal mucosa must be left. The second step of the operation, equally important with denudation, is the plan of introducing the sutures. The object of the special planning of the sutures is to lift the lax vaginal outlet upward toward the pubic arch, restoring the vaginal condition. The skill in planning the denudation in the right and left sulci of the vagina is no less than that employed in the introduction of the well-devised plan of sutures. The chief materials for sutures are silver wire, silkworm gut, and catgut. To suture the denuded surface expose one of the triangles in the lateral vaginal wall. Begin to suture at its apex, passing the suture transversely across the angle, after which immediately tie it. The second suture is passed one quarter of an inch from the first (four sutures to the inch). The needle is passed through the vaginal wall and subvaginal tissue toward the operator (in an anterior posterior direction), whence it emerges, and is re-entered at the same point and passed in an antero-posterior direction under the subvaginal tissue through the denuded triangle, emerging on the vaginal mucosa at the edge of the wound. This makes the suture, before tying, represent a triangle, with its apex (at the emerged points of the suture in the denuded triangle) toward the operator, and characterizes the plan of suturing i e, they are introduced in an antero-posterior direction, and by tying, they lift the vaginal outlet toward the pubic arch. The next suture is introduced by passing the needle through the vaginal wall (on the internal side of the triangle) deep into the subvaginal tissue of the denuded triangle (directly toward the operator), whence it emerges and is re entered at the same point and carried upward and outward (away from the operator) very deeply under the denuded area, emerging on the vaginal mucosa at the external side of the triangle. The sutures on the external side of the denuded triangle should be especially deep and should include extensive tissue. Generally three or four sutures are sufficient to close the triangle of each sulcus. The suture at the base of each triangle may be called a tension suture. It can be tied as soon as passed, which will enable more superficial sutures to be applied to the upper part of the triangle. The crown or pursing suture is now passed within the vagina by introducing the needle in the mucosa on the lateral vaginal wall close to the incision, a short distance below the center of the triangle. The needle should emerge in the subvaginal tissue in the sulcus below the point of introduction. The needle is re-entered and carried across the vaginal sulcus just below the vaginal incision, emerging at the opposite side. One or two auxiliary pursing sutures are added and the several sutures tied, superficial sutures are then added, as required, to close the gaps in the wound. The deep sutures should be of silkworm gut and the superficials of catgut

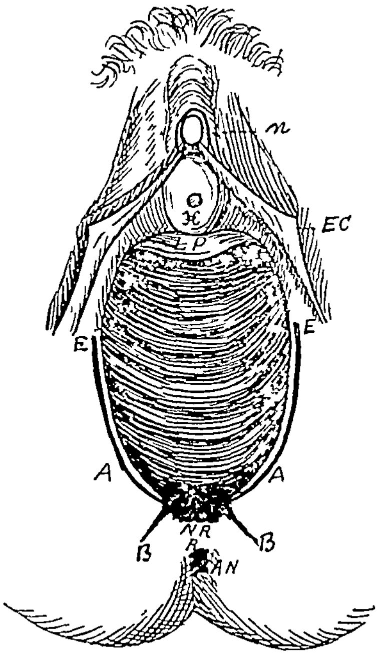

Fig 42.—The outlines of the anterior "cuts" (A E) and posterior "cuts" (A B) in the flap colpoperineorrhaphy n Clitoris h urethra L P, anterior vaginal wall A, N anus N R perineum E C labia The vaginal orifice is wide open The laceration is not complete i e it does not reach the rectum,

In this essay it is not the purpose to discuss immediate repair after labor, but the views are directed toward chronic damage of the vulva, vagina and pelvic floor. It will require careful examination of the vulva, vagina and uterus to decide in certain cases what will be the wisest plan to pursue. Some cases show extensive laceration with but few symptoms, while others show little damage, but complain of severe suffering. Such differences rest on visible and invisible supports. Extensive perineal lacerations demand repair whether they create symptoms or not, as such lesions will in all probability lead to illness. One may occasionally meet a patient who has had a perineal operation, and the perineum to all intents and purposes appears normal, yet an examination reveals the fact of a rectocele above the restored perineal body, and the patient confirms the results of the examination by still announcing herself as suffering. In operating, the dissection of the so called perineal body should extend as high on the recto-vaginal septum as there appears redundancy of the posterior vaginal wall (rectocele). Nothing less will cure the patient. The perineal body in its broadest sense, is a resistant ligamentous, fibromuscular structure which closes the abdominal cavity below. The body begins to be supported from the curved white line located on each side of the pelvis, as one may be impressed by looking into a pelvis from above. It is bowl-shaped, and as soon as this peculiar shape becomes lost, the supports have given away at some point. Observed from below the perineum is narrowed to the space between rectum and vagina. The flap operation is capable of repairing any defect in the pelvic floor. In complete laceration the anal and vulvar orifices are in direct communication, like a cloaca. The rectovaginal septum may show a boot-jack angle or an irregular arched outline. The irregularly-torn outline of the rectovaginal septum shows a double walled layer or curved sides. At the upper angle of the lacerated rectovaginal septum the rectal mucosa pouts, rolls and appears as a red or pink ground which aids in locating the line to split the flaps

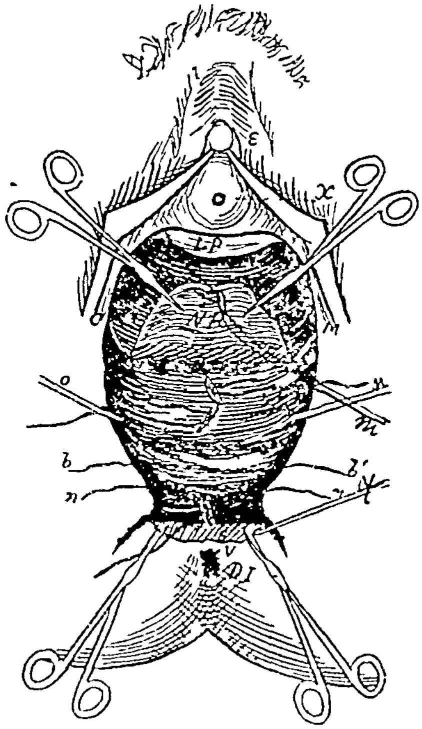

Fig 43.—Dissection of the flap and the anterior vaginal wall V R drawn up with forceps. The posterior flap S is drawn backward by forceps two sutures b n are already passed three more sutures one being introduced by passing the curved handled needle from the lateral edge of the wound to the middle of the denuded surface and threading it from the median line with silkworm gut D I anus V perineum L clitoris X, urethra L P, anterior vaginal wall

After the rectovaginal septum has been lacerated for a long time it presents irregular cicatricial bands, some of which are thin, others thick, assuring different stages of atrophy and contraction Bridges or bands of tissue may stretch from one point to another showing a penetrated condition Again, the lower edges of the lacerated rectovaginal septum may be drawn upward by the fibers of the levator ani still embracing the parts by the aid of its double fascial sheets Besides small, irregular depressions may be felt or observed where the stump of a bundle of the levator muscles has been torn away and retracted The deep sutures applied after splitting the septum will include these stump ends of the muscles by means of fascia so that they may be again forced to the median raphe and fixed there The flap operation does not need to observe whether the sphincter, anus or rectovaginal septum be lacerated, for it is alike applicable to each and all On examination we may find all kinds of associated conditions with extensive colpoperineal lacerations, as lacerated cervix, subinvolution of the vagina, cystocele, rectocele, and retroversion of the uterus Now if the uterine appendages are freely movable we can generally cure the patient by curettement, repair of the cervix and colpoperineorrhaphy, for much of the disease observed is due to disturbed circulation The vessels have been torn from their supporting bed by the deranged fascia The veins have become straightened out, dilated locally, and have lost their elegant spiral form, resulting in blood stasis, congestion Restore the supports and circulation will resume

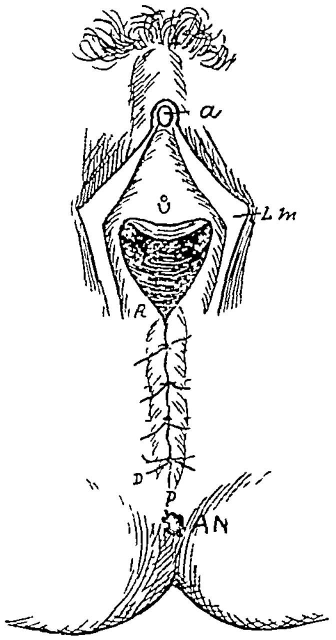

Fig 44 —Sutures tied in the operation for colpoperineorrhaphy with incomplete laceration A, N anus L, M, labia A, clitoris V, urethra, R, D median line of the perineal raphe, P, posterior point of perineal space

The diagnosis consists of observation and palpation with the aid of a large Sims speculum In the diagnosis a notably striking feature is the changed appearance of the vulvar outlet Normally the perineum is widest at its upper end With lacerated perineum or relaxed vulva the whole external appearance is changed The narrow puckered chink or slit-like aperture of the natural vulvar orifice is transformed into a patulous gaping Again the normal vagina presents a sigmoid curve with the posterior vaginal wall coapting and embracing the anterior, like a valve But in deficient vaginal apparatus these two concentric coapted curves have lost their relations, especially the posterior vaginal curve It should be remembered, in diagnosing this deficiency at the vulva, that the non-closure is not due especially to loss of the perineal body, but to defect in the levator ani muscle and its double fascial layers The levator ani muscle endows the rectum with its anterior curve and drags the lower end of the vagina upward and forward against the pubic arch This fact can be demonstrated by introducing the finger into the vagina and forcing backward and downward, when by removing the finger, the vagina quickly returns to its normal position The vaginal orifice has no distinct sphincter like the mouth or anus, but has an indirect sphincter, the horseshoe loop of the levator ani, aided by the pubic arch The arch acts like a fixed point and the vagina is indirectly closed by shortening, contracting of the anterior bundle of the levator ani muscle The vagina is closed by flattening its walls antero-posteriorly between the rectum and pubic arch It is H-shaped There is a slight puckering of the vagina at its external orifice by means of the weak bulbo cavernosus muscle, but practically this amounts to nothing in physiology and anatomy On account of the position of the rectum in relation to the levator muscle it produces a sigmoid curve to the rectum, with its convexity forward This is due to the fact that the strongest bundles of the levator muscle encircle the rectum about an inch above its orifice or lower end, whence by contraction it yields at the point of greatest force, i e, at the sigmoid bend On account of the position of the vagina, levator ani and pubic arch, the lower end of the vagina is dragged upward, producing its sigmoid curve forward, in the opposite direction to that of the rectum In other words, the plane of the pubic arch is anterior to the plane of the levator ani muscle, and when it contracts it must necessarily drag the lower end of the vagina upward and forward These considerations may be appreciated by introducing the finger into the vagina and the

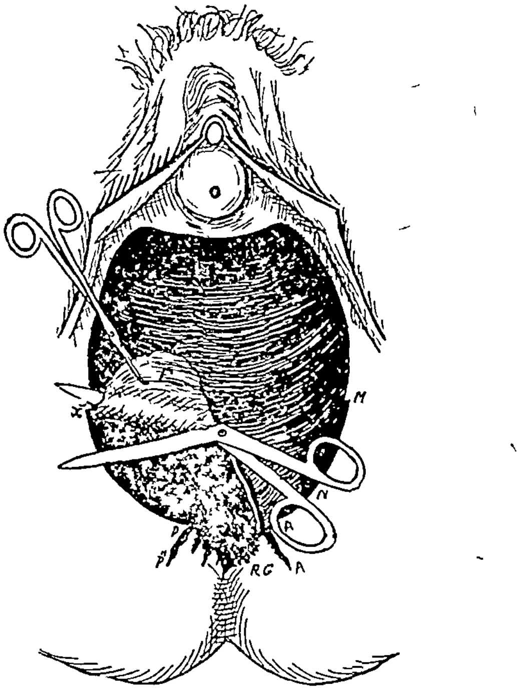

Fig 45 —Flap formation in a case of complete laceration of the recto vaginal septum into the rectum The scissor blade is splitting the vaginal from the rectal wall to form the flap, F, whose margin comes from the mucocutaneous line X, P P, P, is the back cut A to A, the opposite back cut, A, M, the anterior scissor clip

thumb into the rectum It is best studied first on a multipara and second on a nullipara, and third on one with a deficient vaginal sphincter apparatus The closure of the vagina well forward toward the pubic arch produces a kind of valve, which acts almost as a certainty against prolapse while intact This is one of the elements of success in both the Emmet and Tait perineal operations The vast difference in appearance between the virgin and the relaxed vaginal sphincter apparatus of the multipara is due to the yielding of supports by the process of labor in nearly all cases (visceral ptosis excepted) This does not appear so strange when we consider that the virginal passage of the vagina is about an inch in diameter, while the passing head, shoulders and breech demand ten to twelve inches in diameter It is not strange that tissues forced to stretch from one to twelve inches should forget to return The levator ani muscle is arranged in fasciculi or bundles, or it would become defective more frequently The sphincter and vaginal apparatus may be injured by external accidental trauma, but labor is the chief factor

(To be continued)

SOCIETY PROCEEDINGS

American Public Health Association

Twenty sixth Annual Meeting, held in Ottawa, Ontario, Sept 27-30, 1898

The American Public Health Association for the third time in its history met in the Dominion of Canada, this being the twenty sixth meeting since its organization in 1872 It was feared that the prior quarter centennial jubilee of the State Board of Health of Michigan and the coincident meeting of the Conference of State Boards of Health at Detroit in August, and the unfortunate announcement of the meeting of the Illinois Auxiliary Sanitary Association at Chicago on the same date as had been months before published as having been selected by the executive committee for this twenty sixth annual meeting, would affect the attendance, but this did not prove to be the case, the number of old members present, having a record of fifteen to twenty or more years of service, being particularly noticeable The Mexican and Canadian members were as earnest and conspicuous in their participation in the work of the Association as they have ever been since they became constituent parts of the organization, their papers being of that high order which habitually characterizes the contributors to the transactions It was a matter of comment that six of the former presidents were present, three others having been prevented from coming by unavoidable official duties This attendance of so many ex presidents is especially gratifying, since it shows the wisdom of the provision of the constitution of this Association making them ex officio members of the executive committee, thus securing that uniformity and persistence of policy which are so apt to be influenced in a body changing its locality and officers from year to year About seventy five new members were added to the rolls, an unusual proportion of these, as well as of the contributors of papers, being non medical men interested in sanitary matters The character of the papers was far above the ordinary, many of them, in the shape of exhaustive committee reports, precluding any satisfactory abstract or epitomizing, without injustice to the writers and reporters This, however, is less necessary since the executive committee, at its preliminary meeting on Monday afternoon had unanimously resolved to abandon the quarterly form of publication of the transactions and revert to the annual volume, which had been formerly issued, the publication committee having announced its intention to have the transactions of the current meeting [illegible] and distributed within two months after adjour[illegible]

TUESDAY, SEPTEMBER 27—MORNING SESSION

The routine sessions of the Association were held at the Parliament Buildings, where, at 11 30 A M , Tuesday, September 27, the Association was called to order by the President, Prof CHARLES A LINDSLEY, of Yale University, Secretary of the State Board of Health of Connecticut, who introduced the Chairman of the Local Committee of Arrangements, Dr JOHN SWEETLAND, Sheriff of Ottawa, by whom the customary announcement of proposed entertainments, etc , was made

The carefully prepared minutes of the preceding meeting at Philadelphia in 1897, were then presented by the Secretary, Dr CHARLES O PROBST, secretary of the State Board of Health of Ohio, but having been already published in the quarterly transactions, they were affirmed without reading

The Secretary then read the report of the executive committee, always a matter of the greatest interest in this body, which while conferring extraordinary powers upon the committee in the matter of the revision and amendment of resolutions, the digestion of propositions, the suggestion of courses of procedure, etc , jealously exercises its own prerogative of final approval or veto

1 With respect to the resolutions offered at the preceding meeting by Mr Henry Lomb of Rochester, N Y , contemplating the publication of journal appeals on the part of the Association to State, municipal and town corporations and the widespread distribution to the public, through the newspapers of this appeal, urging the necessity for the establishment of local sanitary organizations, the committee reported that it was of opinion that the measures for the enforcement of regulations designed to prevent the spread of disease could be best advanced by employing men educated in sanitary science as sanitary agents and inspectors, and that this could be best accomplished through the establishment of separate institutions for the education and training of such sanitary inspectors The resolutions, as amended by the committee, were adopted after discussion by Dr Benjamin Lee of Philadelphia, Pa , who said that all institutions should have departments of sanitation, since naturally, health officers and inspectors would be of a better and more efficient class if properly instructed in sanitary science, whereas the fact is, that in the United States men are put in positions for the enforcement of regulations for the protection of the health of the community who are not qualified to serve, and this because they have had no opportunities of prior education, and by Dr Henry Mitchell of Asbury Park, N J , who said that the United States ought to pay tribute to England in this matter, where for twenty years a system has been in operation for the training of men for the inspection service, and though it is not obligatory to have a certificate of the Sanitary Institute as a precedent of employment, still it is customary to employ such by preference In New Jersey the first step has been taken toward the training of sanitary inspectors Rutgers College of New Jersey has already begun to grant certificates of competency in matters relating to details of the sanitary inspector's duties The resolutions offered are designed to encourage this effort, especially for the education of executive sanitary officers The men engaged in this work are usually physicians, who have no knowledge of the practical details of their work, which they have to learn for themselves in the school of experience, so there ought to be post graduate courses in colleges to supply the particular information lacking

2 The second resolution reported by the executive committee with the recommendation that it be adopted, which was done, directed the publication committee to abandon the form of publication of the transactions in quarterly issues, and return to the former plan of a single annual volume, uniform in type paper, size, make up and binding with such volumes, the chairman of the publication committee having explained that it was entirely feasible to have their single volume printed and distributed as soon as the first number of a quarterly series could be issued

3 The resolutions offered by Dr Cressy L Wilbur of Lansing, Mich , Chairman of the Committe on Demography and Statistics in their Sanitary Relations, were recommended for adoption, which was unanimously done, and seventy five dollars appropriated for the necessary clerical work of the special committee in carrying them into effect The resolutions contemplate the procurement of the establishment of Vital Statistics officers in non registration States, the general adoption of the Bertillon system of identification as a basis of classification, the institution of [illegible] methods of registration in the next census report, [illegible] establishment of an international alliance and [illegible] ethod between all national and foreign depart[illegible] tistics

The resolu[illegible] revious meeting to reduce [illegible] l due [illegible] three was referred back without recommendation, and was on motion laid upon the table by the association

The Secretary then read the names of fifty applicants for membership, who were recommended for election, which was accordingly done

The reading of papers announced upon the program was then begun with

A SHORT HISTORY OF SEWAGE DISPOSAL AT THE ASYLUM FOR INSANE AT LONDON, ONT ,

by Dr R M Bucke, superintendent, the paper being read in the absence of the author, by Dr Peter H Bryce, secretary of the Provincial Board of Health of Ontario

Dr Bucke described the various systems of sewage disposal at this hospital since its opening for the reception of patients in 1870, down to the present day The sewage was first thrown into a small creek, a branch of the Thames, which in dry weather constituted a nuisance of which the neighbors complained Charcoal and gravel filtration was in vogue, with varying success, for fifteen years Complaints were made from time to time and intensified by the appearance of typhoid fever in London The system of intermittent downward filtration was finally instituted Alternate beds and trenches with drainage through tile lined conduits were spread over a wide area but experience showed the latter were useless, and when subsequently taken up it was found that nothing had passed through The sewage beds are on a higher level than that of the asylum One thousand inmates, of whom two hundred are sane people, produce daily 75,000 gallons, requiring two and a half hours to flow through to the beds, and in six hours it is completely absorbed in the soil, reappearing as pure spring water There is no pollution of the soil The sewage always disappears The experiment of establishing a vegetable garden has been successful, crops of fruit and vegetables of the value of $200 to the acre having been produced The system of sewage disposal so completely satisfactory at Dr Bucke's institution is simply nature's own plan of refuse riddance by returning it to the earth

Thomas Macfarlane, Esq , F R S C , chief analyst of the Inland Revenue Department of the Dominion of Canada, followed with a paper entitled

REMARKS ON THE DISPOSAL OF REFUSE IN SOME EUROPEAN CITIES

detailing results of official visits and inspection of the methods in vogue in England and Germany He agreed with Dr Vogel that no one method can be arbitrarily said to be the best everywhere In his opinion the direction of improvement in the large cities lies in the exclusion of surface water, and in towns of 30,000 inhabitants, he believed the moss litter system will be the best, as used at Caledonia Springs, Ont He exhibited a specimen of moss litter, which he described as an intermediate form of peat He strongly indorsed the system practiced at the asylum for the insane at London, Ont

Mr G G Horetsky, C E , read a paper entitled "The Most Recent Methods of Sewage Disposal and their Application to Certain Cities in Ontario," and was followed by Capt W F Van Buskirk, C E , of Stratford, Ontario, "On the Filtration of Sewage "

Discussion of the groups of papers on sewage disposal was opened by Dr Hurtig, secretary of the State Board of Health of Indiana, who, having inquired of Mr Macfarlane, where moss litter can be obtained, was told by the latter that it was found on the upper layer of broad savannas in Canada and that it was simply moss which had ceased to live It was not peat, but was intermediate between this and the green moss of the surface It differs from peat in that it is spongy and can be broken up while peat can not be Moss litter has an extraordinary power of absorbing moisture and ammonia, which makes it valuable for bedding in stables It gives off its absorbed water readily but retains the ammonia It is eight times more effective than dry earth , one hundred pounds of it will render inoffensive eight hundred pounds of excreta

Dr Boardman of Ottawa said the objection to most methods of sewage disposal was the fact that the products of the several expensive mechanical processes have no value

'The Interpretation of the Chlorin Number in Well Waters" by A McGill, Esq , M A , was read by title and was followed by a paper on

THE FARM WELL

by F T Shutt, Esq M.A , urging the importance of instructing the rural population as to the dangers to health from the polluted wells, since four fifths of the population reside outside of the cities, and cited the barnyard well as an especial and very common source of danger

Mr Macfarlane dissented from the opinion that legislation can not accomplish much but that we must trust to education, and said that education was a very slow process If only existing legislation is properly carried out, it will accomplish much Health officers have the right, if they can fearlessly exercise it, to expose existing nuisances and call the attention of the authorities to them, and this as well with respect to the care of cattle and the supply of water for man and beast

Dr Probst of Columbus, Ohio, said that there was no doubt that the majority of cases of typhoid fever in rural districts was due to impure well water, and recited an interesting case in his experience as member of the State Board of Health of Ohio of a recent outbreak of twenty one cases of the disease in a locality where fifty years ago a similar outbreak had occurred A well used at that time had been filled up and abandoned for over thirty years New owners came into possession, and the old well, which was in the side of a hill, was cleaned out and deepened—and its use followed by the renewed poisoning of those who drank its water

Dr Patterson of Winnipeg, Manitoba, said there was no doubt that typhoid fever is the prevailing disease of this region and equally no doubt that polluted well water was its source, and he insisted that the necessity that the farm well should be abandoned is as great as that privies in cities should be disused

Dr Hurtz agreed with the other speakers as to the objectionable sites of the ordinary farm well and insisted that it should be in front of the house instead of in the rear as customary

Dr Curtis of Ottawa, did not think cementing a well was sufficient to exclude polluting agents

Tuesday, September 27—Afternoon Session

Dr John L Leal, Health Officer of Paterson, N J , read a paper entitled

AN OUTBREAK OF TYPHOID FEVER DUE TO AN INFECTED PUBLIC WATER SUPPLY,

which he presented because it established the fact that a single case of typhoid may so infect a large body of water as to reproduce itself among those dependent upon this same body of water for their public supply, even though said supply was taken at some distance from the point of infection Most hitherto well authenticated outbreaks of typhoid fever have been where the infected water was small in bulk or the infection great and its action more or less continuous In this outbreak, the bulk of water infected was large, its infection sharply defined, and its origin in a solitary case of typhoid in the person of a resident, who returned from a summer resort ill with the disease The water closet receiving the discharges of this patient was connected with a series of cess pools by overflow pipes the last of the series discharges through a hidden pipe into the river, which was more or less continuously infected from September 18th to November 14th, when the hidden discharge pipe was discovered and further infection from that source prevented Subsequent to this, the cases of disease gradually diminished and within a fortnight entirely ceased Dr Schwartz of Rhode Island and Dr Connelly of New Jersey, commented upon Dr Leal's paper without questioning his conclusions

The Report of the Committee on "The Cause and Prevention of Infectious Diseases" was presented by its Chairman, Dr Peter H Bryce of Toronto, secretary of the Provincial Board of Health of Ontario , ordered to be printed, and the committee continued The excellence of Dr Bryce's report was universally admitted Its literary merit, conciseness of expression and exhaustive character entitle it to be considered among the admirable committee reports, which have emanated from this association

WHAT CONSTITUTES AN EPIDEMIC?

was the title of a paper read by Dr Benjamin Lee, secretary of the State Board of Health of Pennsylvania and Health Officer of the city of Philadelphia, and which ably discussed the question as to whether numbers of cases, rapidity of spread or malignity of disease should determine the epidemicity of an outbreak Machiavelli uttered the famous aphorism "Words are the counters of wise men, the coin of fools " Another equally distinguished diplomat (liar) has informed the world that the object of language is to conceal ideas In the word *epidemic*—a "coin" or a "counter"—practically, as employed at the present time, it is simply used to describe the presence of a communicable disease in some other fellow's town " Inasmuch as the reluctance of the resident physicians and especially the authorities of a town, to acknowledge the existence of an epidemic is founded upon a purely commercial basis, having no other motive than the fear of the diminution of trade, while the readiness of those of the neighboring town to proclaim it is based upon a wholesome and instinctive aversion to contracting the supposed infection, is it not remarkable that the view of the latter rather than that of the former should be adopted as that of the sanitarian? In other words should not rapidity of spread rather than the number of cases be recognized as the true test? Dr Lee's contention is that the actual number of cases of a contagious disease in proportion to the population as the criterion for the declaration of an epidemic "has nothing to do with the case any more than the flowers that bloom in the spring," but that the rapidity of spread shyuld be solely considered The Board of Health which, having knowledge of such condition, purposely conceals it, or still worse, denies it, is guilty of a crime of hideous proportions, none the less so because it is acting in obedience to the behests of the business portion of the community or from a mistaken sense of local patriotism

The discussion following the report of Dr Bryce and the paper of Dr Lee became general Respecting the former, Dr Gehrman of Chicago suggested the question as to the proper time of isolation of diphtheritic cases, since the bacillus often persists after the case is apparently well

Dr Holton of Brattleboro, Vt , spoke of the undoubted presence of the bacillus of diphtheria in individuals who have not been sick with the disease He asked what should be done with people going around with them who are apparently well? Is it fair to quarantine those who have been ill and yet who are apparently well, but still have bacilli discoverable in their throats?

Dr Bracken of Minneapolis, Minn , said if any healthy person was found to have the bacillus in his throat he ought to be quarantined The time limit in Minnesota was four weeks

Dr Chapin of Rhode Island thought it very rare that the bacillus was found in healthy people, but he believed it to be equally dangerous In families where diphtheria has prevailed about 20 per cent are found to have bacilli in their throats In an orphan asylum within his knowledge, twenty five cases of the disease occurred, and about 20 per cent of all the children were found to have bacilli, and of these two or three became sick with the disease, and one case was carried to another institution by a child who was not sick

Dr Patterson of Winnipeg, Man , knew of three cases, in one of which the bacillus was found thirty days, in a second thirty five, and in the third forty days after they were severally supposed to be well

Dr Jones, health commissioner of Baltimore, detailed the precautionary measures enforced in that city , Dr Probst of Columbus, Ohio, Dr Burroughs of Asheville, N C , and Dr Wright, of New Haven, Conn , spoke of the practice in their respective cities

Dr Schwartz, secretary of the State Board of Health of Rhode Island, asked, referring to Dr Lee's paper, whether tuberculosis ought not to be considered epidemic throughout the civilized world

Dr Lee said that the distinction ought to be made between endemic and epidemic, under the former of which tuberculosis might be properly classed

Dr Wingate, health commissioner of Milwaukee, Wis , thought a special committee might be created to define "What is an epidemic?" and offered a resolution to this effect, which was referred to the executive committee The discussion was closed by Dr Hurty, the secretary of the State Board of Health of Indiana

The paper presented by Mrs Ellen H Richards, of the Institute of Technology, Boston, Mass , on "The Urgent Need of Sanitary Education in the Public Schools," was read by Dr Henry Mitchell, secretary of the State Board of Health of New Jersey The writer claimed that the Cuban war has shown that sanitation has not been taught to the people, and that the only way in which this can be reached is through the public schools The lamentable ignorance of the volunteer soldiers in matters of food and clothing would not have existed had they been properly educated Professor Robinson of Bowdoin College, Brunswick Me , and Medical Director Gihon, U S N , dissented from the opinion that public school education could accomplish much in this direction

Dr Hurty of Indiana read the paper on "Theater Sanitation," prepared by Mr William Paul Gerhard, C E , of New York City

Evening Session

The customary public meeting for the formal reception of the Association by the local authorities and the annual address of the President was held in the city hall and was opened with prayer by the Rev William Moore D D

Addresses of welcome were then delivered by Hon Sydney Fisher, M P , Minister of Agriculture whose department embraces the sanitary interests of the Dominion of Canada by Sir James Grant, M D K C M G , F R S C by Samuel Bingham, Esq , Mayor of Ottawa, and by W G Black, the several speakers being introduced by Dr John Sweetland, chairman of the local committee of arrangements

Dr Gregorio Mendizabal of the City of Mexico responded eloquently in French to the special greeting extended to the Mexican members

Dr Benjamin Lee of Philadelphia then took the chair, introducing, after some witty and felicitous remarks, the president of the association, Prof Charles A Lindsley, M D , of New Haven, Conn , who then delivered the President's Annual Address

Wednesday, September 28—Morning Session

The Association was promptly called to order by the president at 9 o'clock, to permit acceptance of the excursion to Hull, Aylmer and Victoria Park and thence on the Ottawa River to Chats Falls and a dinner at Victoria Hotel, Aylmer, P Q , tendered by the municipality and citizens of Ottawa

Dr Probst, the secretary, reported from the executive committee the resolutions offered by Dr Wilbur of Lansing, Mich , for the appointment of a commission of nine members, three from each of the nationalities represented in the association, to co operate in the establishment of bureaus of vital statistics for the collection of such statistics under the Bertillon system of classification, and these were adopted as recommended

The names of twelve new members were recommended for election and were accordingly elected

The report of the committee "On the Etiology of Yellow Fever" was then presented by the chairman, Dr Henry B Horlbeck, health officer of Charleston, S C , and a supplementary report on the same subject by Dr Eduardo Liceaga, president of the Superior Board of Health of the Republic of Mexico, a member of the committee

The committee was continued, and also the committee of seven appointed at the previous meeting to wait upon the President of the United States with a view of obtaining the appointment of a bacteriologic commission to go to Havana to study the causes and methods of prevention of yellow fever This special committee was reconstructed to consist of Dr Henry B Horlbeck of Charleston, S C , George M Sternberg, Surgeon General U S Army , Dr Alvah H Doty of New York City, Dr Samuel H Durgin of Boston Mass , Dr R D Wilkinson of New Orleans, La , Mr Josiah Hartzell, and the State Health Officer of Texas, to succeed Dr R M Swearingen, deceased

Dr Liceaga presented the seventh of a series of reports on yellow fever, to modify a former statement in the report of last year, that "there are only two foci of endemic yellow fever in the whole of the Gulf Coast of Mexico and these foci are found in the Canton of Vera Cruz and in the district situated in the northern part of the Peninsula of Yucatan " This statement was made before the Superior Board of Health had absolute knowledge of the two cases observed in Campeche and before the appearance of the epidemic in Tampico, and consequently before the investigation was commenced which proved that these cases were *not* the result of the importation of the disease Hence, Dr Liceaga said, we have to withdraw our absolute statement that there are only two foci of endemia on the Mexican Coast of the Gulf of Mexico Dr Liceaga's declaration that the sanitary authorities of Mexico have firmly resolved *never* to hide any case of transmissible disease that may come to their knowledge and that they have determined that their official documents shall express the truth only so far as absolute facts are known, was greatly applauded—as an evidence of the proper spirit in which the work of the committee of which he is a member should be conducted

Dr Walter Suiter of Herkimer, N Y , Dr Wilkinson of New Orleans, La , and Dr S W Battle, U S N , participated in the discussion of the reports of Drs Horlbeck and Liceaga, eliciting the declaration that there was no analogy recognized between any of the forms of malarial fever that the 'calentura" of Mexico is paludic, and that neither it nor the severest forms of bilious remittent fever give any immunity against an attack of yellow fever , that the microbe of Laveran is positively distinctive , that so far the microscopic germ of yellow fever can not be said to have been discovered but that the bacteriologic investigation which it is the object of Dr Horlbeck's special committee of seven to induce the President of the United States to inaugurate, may confidently be expected to reveal its identity

The report of the committee "On the Cause and Prevention of Infant Mortality" was then presented by the chairman Dr Ernest Wende, commissioner of health of the City of Buffalo, N Y , and pursuant to the recommendations of the committee, Dr Suiter of Herkimer, N Y , offered the following resolution, which under the rules, was referred to the executive committee

Resolved, That it is the opinion of the Public Health Association that the State, city and town health authorities and local sanitary societies generally should exercise every possible effort to procure the enactment of laws in their respective States, cities, towns and villages to prohibit the sale of the so called long rubber tube nursing bottle as being a perniciously active agent in the cause of preventable disease in infancy of the most serious character and fatality

Dr Irving A Watson of Concord, N H , president of the State Board of Cattle Commissioners and secretary of the State Board of Health of New Hampshire, read an admirably written paper entitled

SOME OBSERVATIONS FROM PRACTICAL EXPERIENCE WITH BOVINE TUBERCULOSIS IN NEW HAMPSHIRE

The tenor of the paper was to the effect that the danger of infection from bovine tuberculosis has been greatly over-rated and that whatever danger exists arises almost entirely, if not wholly, from those animals in which the disease is so far advanced that it may be detected by a competent veterinary surgeon upon physical examination, barring, possibly, the localized appearance of the disease in the udder, in which event the tuberculin test would determine the diagnosis The following concluding propositions were presented

1 That it is impossible to eradicate bovine tuberculosis, but that it may, without inflicting too great a burden upon the State, be reduced to a degree that will subserve the interests of the stock raisers and likewise protect the public health

2 That a very small percentage of the animals infected with tuberculosis in any way endanger the public health, and that an indiscriminate slaughtering of the cattle reacting to the tuberculin test is wholly unnecessary, inasmuch as many of them either recover or the disease is permanently arrested

3 That a proper sanitary condition of stables and stable inclosures would do more toward preventing the spread of bovine tuberculosis than any other measure that could be adopted

4 That the danger of infection from bovine tuberculosis may be reduced to very small proportions, if not wholly eradicated, by sanitary measures, inspections and physical examinations by the State, in co operation with local authorities

5 That such inspections once inaugurated could be maintained without an expense that would be burdensome to the State

Dr A de Schweinitz, chief of the Biochemic Division of the Bureau of Animal Industry, Washington, D C , read a paper on "A Convenient Method of Staining Tubercle Bacilli "

Sir James Grant, M D , of Ottawa, commended very strongly the propositions advanced by Dr Watson

Dr Gibson of Iowa dissented as to the ability of veterinarians, however skilful and experienced, to recognize tuberculous cattle by mere physical examination however thorough He would quarantine a tuberculous cow reacting to the tuberculin test as he would a glandered horse The slaughtering room is the only place for them

Dr Bracken of Minnesota, deprecated the effect of Dr Watson's paper as calculated to occasion loss of confidence in the tuberculin test

Dr Durgin said that we must have the people with us if we hope to succeed in sanitary work In Massachusetts, radical and extreme measures had been found to defeat their object

Dr Woodward, health officer of the city of Washington, asked who were the people—the dairymen who sell, or the citizens who consume the milk? In Washington the people themselves demand the application of the tuberculin test

After further remarks by Dr Bryce of Toronto, and Dr de Schweinitz of Washington, Dr Watson closed the discussion, defending the propositions he had presented, and the association then adjourned until Thursday morning, to accept the courtesies tendered by the city of Ottawa for the afternoon and evening

(*To be continued*)

Cincinnati Academy of Medicine

Regular Meeting, September 26

Dr Merrill Ricketts exhibited a patient who had been operated on just one week previously for right inguinal hernia The radical operation was the one performed The operator reported the case as he wished to call attention to the short time the operation required, eight and one half minutes, and also to emphasize his opinions as to the great value of properly prepared kangaroo tendon for buried sutures The sutures he always kept, until used, in alcohol, to which a little resin had been added The resin he claimed prevented the hands slipping when the suture is pulled home

Dr Lyle exhibited the specimens of a case in which a tubercular infection had involved the pericardium and peritoneum, while the lungs were but little diseased The trouble probably originated in the bronchial glands The pericardium showed a caseous exude about half an inch thick over the left ventricle and about a qurter of an inch over the right side of the heart In the abdomen was found, in addition to the tubercular peritonitis, great thickening and involvement of the omentum The stomach had been invaded by a large carcinomatous growth at the pyloric orifice, this had ulcerated through into the general peritoneal cavity, which proved to be the immediate cause of death The man was 44 years of age Dr E W Mitchell, who had had the case before he had been sent to the consumptive hospital, had had considerable trouble *in deciding upon the diagnosis The examination of the blood* repeatedly showed the absence of the plasmodium, and the reaction of Widal had also proved negative The lungs were apparently normal The stomach contents showed the absence of free hydrochloric acid, and also of lactic acid Chills and fever occurred not infrequently The use of tuberculin was determined upon for diagnostic purposes, but the first injection proved entirely negative Not satisfied with this, however, a new solution was obtained, and the injection this time was entirely successful, a decided chill, some fever, and marked constitutional reaction following

Dr Magnus Tate reported a case in which a double pyosalpinx operation had been performed, the patient at first reacting strongly, within forty eight hours of the operation, she unfortunately fell out of bed, soon collapse set in, and in spite of every aid, she went from bad to worse and soon died Opening the wound, just before death, he found a small opening in the gut The case, during operation, has been a most difficult one on account of strong adhesions present He had been most careful to examine the bowel before closing the external incision for this very thing, but had been unable to find a weak point He thought that the accident after the operation had caused some weak point to give way under an increased strain Discussion was by Drs Reed, Bonnifield and Zinke, who agreed with the speaker as to the cause of the perforation

Dr Ed Ricketts reported a case of appendicitis in which a concretion had ulcerated through the appendix, producing a fatal peritonitis He also exhibited a gall stone he had removed by operation, which weighed 388 grains Discussion was by Drs Twitchell, Reed, Zinke and Bonnifield

Dr Meyer Heidingsfeld read the report of a case of spontaneous rupture of a prostatic abscess into the rectum and urethra, followed by recovery L A , 21 years of age, was *infected with gonorrhea on July 3, prostatic abscess formed* and opened into the rectum on July 30 Reinfection from the rectum followed, a second abscess formed and ruptured spontaneously into the urethra, August 30 The case then became complicated with epididymitis, hydrocele and abscess of the left testicle, which latter was incised, and patient was discharged one week later without urinary fistula

Dr S E Allen reported a case of mastoiditis in which septic infection with the formation of abscesses in various parts of the body occurred without involvement of the lateral sinus He thought that the emissary veins carried the infection

The German Congress of Ophthalmology

Held at Heidelburg in August

Landolt of Paris presided at the first session The first address was by Norman Hansen of Copenhagen on

SYSTEMATIC SUTURE OF THE CONJUNCTIVA ALONE WITHOUT SUTURE OF THE SCLEROTIC, FOR SEVERE WOUNDS OF THE EYEBALL

He recommends suturing the conjunctiva, even in deep perforating wounds This protects from infection and produces an even pressure which holds the lips of the wound in contact on an even plane In all cases of large perforating wounds of the sclerotic, with or without the participation of the cornea, he first enlarges the conjunctival wound to the corneo sclerotic limbus and then carries the scissors half around the corneal margin, detaching the conjunctiva, with the subconjunctival tissue, after which the two flaps are drawn together over the wound in the sclerotic and over the corresponding segment of the corneal surface, with two or three fine stitches He then applies a cotton pad, held in place with a wide gauze bandage, but without *compression* He changes the pad twice a day on account of the copious serous, non-infective secretion His clinical experience proves that this suture is sufficient to prevent infection and that it is an effective defense against prolapsus of the vitreum and choroidea Experiments have shown that the largest wound gap in the sclerotic is completely filled with granulations in six days The sutures will certainly hold that length of time if they are taken deep enough in the subconjunctival tissues, and in the episclerotic, with extensive lesions He added that every case he now cures so simply and easily without either primary or secondary infection, is haunted for him by the ghosts of the eyes he has lost in former years with expectant treatment, by primary or secondary infection, staphyloma or cicatricial shriveling If the lens is injured, or it is found difficult or impossible to replace it without loss of vitreous humor, he performs iridectomy, to allow the lens more space The suture in the conjunctiva does not tear out, with cocain it is painless, and it is applicable to the most extensive lesions He related a typic case thus treated a workman hit in the eye by a sharp chisel falling from a height, as he was looking up It cut the eyeball from the upper edge of the cornea to the inferior conjunctival fold, slitting also the iris and lower eyelid, the lens escaping through the long gaping wound He sutured the conjunctiva alone, as above described, over the wound to the center of the cornea The wound healed in ten days and now, a year later, the functions of the eye are perfect, counting fingers at six meters, with a restricted field

Axenfeld explained the fact that the newly born can not shed tears until about the seventh week, due to the unfinished condition of the central nerve tracts, not only the cortical—necessary in psychic weeping—but also the reflex tracks The lachrymal glands are comparatively completely developed

Sugrist called attention to the

DANGER OF BLINDNESS FROM LIGATURE OF THE CAROTIS COMMUNIS OR INTERNA,

describing a couple of observations in which the corresponding eye became atrophied and blind after the carotis communis and interna had been ligated to arrest hemorrhage, during the extirpation of a carcinoma of the tongue in one case In the other, the carotis externa and interna had been ligated in a young man on account of exophthalmus pulsans traumaticus Embolism of the central artery followed in both, and the necropsy of the first case showed a thrombus in the arteria ophthalmica, and an obstructing embolus in the arteria centralis retinæ

Uhthoff reported some cases of "Visual Hallucinations from Affections of the Eyes" a few limited to one side

Silex of Berlin stated that the "Central Innervation of the Muscles of the Eye" is derived from hitzig center, part of the facilis center It controls the voluntary movements of the eye, at least of the abducens and obliquus superior Stimulation of this center in a case of unilateral traumatic nystagmus produced movements in the eye of the opposite side

Abelsdorff stated that Malays, Mongolians and negroes examined were remarkably free from astigmatism of the cornea, compared to civilized races, when found it was very slight

Groenouw judges from a study of forty cases of ophthalmia neonatorum that the clinical picture is not an absolute guide to the bacterial agent of the affection Gonococci were found in the conjunctiva in some cases, after the secretion had ceased The pneumococcus was found in a number of cases It indicated a benign course of the affection

Rahlmann recommended the mucous membrane of the lips for "Marginal Plastic Operations," as owing to its resemblance to the conjunctiva, it is especially adapted to heal in its new situation without delay or alteration of structure

Sattler described his simplified operative treatment of myopia He extracts the lens in cases of extreme myopia without preceding discission, first incising the cornea, 6 to 8 mm , lifting the anterior capsule with a hook and taking out with the Daviel spoon as much of the lens substance as possible The final discission is not hastened Thirty cases thus treated were distinguished by the rapid recovery and slight post-operative astigmatism

On account of the International Congress of Ophthalmology to be held next year, at Utrecht, the German Congress will not convene again until 1900

French Congress of Alienists and Neurologists

Held at Angers in August

The chief subject under discussion at this meeting was

POST OPERATIVE MENTAL DISTURBANCES

As already noted in our editorial (page 798), **Rayneau** stated in his address that all the various pathologic mental conditions have been encountered in the psychoses consecutive to operations, and that there is no special type A hereditary or acquired predisposition is generally admitted (except in certain operations on the skull and thyroidectomy) the traumatism is only the last drop that makes the vessels overflow Some patients even request an operation, simulating a disease if necessary, because they are already mentally affected In a number of cases related, the psychosis following the operation was found to have been preceded by more or less transient mental disturbances in the past when thoroughly investigated Statistics, he stated, show an average of one psychosis to fifty surgical interventions Out of 68 cases on record, 5 have become chronic, 13 lasted a month or two, 33 nearly a year, in six duration is unknown

Regis considers the confusional the usual type Delirium immediately following the anesthesia is due to chloroform intoxication supplementing the nervous shock Delirium appearing from the second to the tenth day is due to septicemia, to accidental infection or to auto intoxication caused by the interference with the nutritive processes by the nervous shock

Picque observed that, in his experience, mental disturbances very rarely follow operations on the uterus and adnexæ, while they are frequent after vaginal or perineal operations on predisposed nervous subjects In these cases the lesions are accompanied by subjective symptoms, and the patient is already under the dominion of a fixed idea when she comes to the surgeon

Terrien described three typic cases of post operative hysteric paralysis and mental disturbances, cured by suggestion supplemented by the thermocautery and electricity, using a different style of battery on account of the "suggestion," if the first proved ineffectual He also urged the necessity of special training in mental pathology in the medical colleges, to enable the general practitioner, particularly in the country, to handle the cases of insanity he may meet Out of nineteen delirious cases in the last ten years, he has only sent five to asylums He treats the rest at home, where they are better off, while it relieves the crowded asylums

Regis attributes the unsettled condition of the question of post operative psychoses to the fact that they are not seen by alienists until fully established

Montprofit reported five in the course of 3000 operations

Grandjux observed that they are not encountered among soldiers, as selection eliminates the predisposed, and that the rôle of the traumatism is insignificant, mentioning as an instance in proof that not a single psychosis occurred among the 931 soldiers wounded at Froeschwiller and exposed to innumerable privations

Ladame called attention to the dangers of morbid suggestion, relating the case of a lad of 10, trephined for some traumatism, but recovering perfectly and in excellent health for years, when he met the surgeon again The latter expressing his surprise and gratification at his patient's good health, happened to describe the mental disturbances that might have resulted from the intervention A psychosis promptly followed

Doleris has recently reported three cases of mental disturbances consecutive to a benign gynecologic operation One patient imagined that the entire external genital region had been removed, unconvinced, except for the moment, by inspection and palpation Another returned again and again for the surgeon to assure her that her anus had not been closed , another was convinced that the perineum was unbroken by any orifices The cases were otherwise in perfect health One recovered after several months of hydrotherapy, exercise and hypodermic injections of glycerophosphate He observes that if we could divine the secret morbidity that leads women to ascribe all their troubles and ailments to the hypogastrium, many interesting problems in gynecology might be solved

The second address, on

TRANSIENT DELIRIUM FROM A MEDICOLEGAL POINT OF VIEW,

classified this delirium according to its etiology as 1, melancholia mania, 2, emotive, 3, brief, irresistible impulses, 4, puerperal and menstrual 5, a neurosis—epilepsy, hysteria, neurasthenia *or ophthalmic migraine*, 6, *intoxication*—alcohol, etc , 7, affection of the nerve centers and nerves, 8 diseases other than nervous, 9, disturbances in sleep—state intermediate between sleeping and waking, somnambulism, prolonged dreams, 10, momentary aberration The French school do not admit the idiopathic, transient insanity accepted by the Germans—Krafft-Ebing, Kroepling Swarzen and Wendel—who believe that a form of transient mental alienation may occur in perfectly normal individuals *free from* any hereditary predisposition and any pathologic anterior conditions such as epilepsy, alcoholic intoxication, etc

Motet has never encountered such a case in all his long experience It has often been difficult to discover the determining cause of an apparently insane act, but he has always discovered it at last, in some cases it was epilepsy, in others intermittent fevers, etc There are crimes of passion which resemble the acts of insanity but must not be confounded with them

Charpentier observed that besides the transient delirium depending upon known causes, there are others whose cause is unknown, but that it does not follow that they have no cause, adding that Motet's experience reminded him of the judge who remarked that during his entire professional career he had never seen a single example of a judicial error He claims that a crime committed during an attack of transient delirium, whatever may be the known or unknown cause of the delirium, does not come under the jurisdiction of the laws which assume criminal responsibility

Lalanne called attention to the transient delirium that may proceed from a transient congested condition of the brain, citing an instructive example

In concluding a discussion of a case of myelitis and flaccid paraplegia, **Pierret** explained the fact that the inferior members have convulsive movements when the neurons controlling their movements are separated from the cortical centers, by the assumption that there is a constant tendency in the entire nervous system to the realization of an equilibrium of latent dynamism, the medullary segment, isolated, is forced rapidly to a condition of exaggerated potentiality whence the discharges, spasmodic in character But healthy cells are indispensable to the phenomenon If the neurons are diseased, if the nerve tubes are altered or if the muscles are no longer normal, the convulsion does not occur The connection between general paralysis and mental degeneracy was noted by Joffroy, although Magnan considers the latter secondary, and that general paralysis depends more upon the "way one lives" than any other cerebral affection It is rare among imbeciles, but ten cases are on record, confirmed by the necropsy

An interesting study of "Arteritis in the Pathology of the Nervous System" was presented by **Coulon**, who restricts its rôle almost exclusively to the secondary lesions it occasions aneurysmal dilatation and the phenomena, generally local, which it determines; diminished size from the thickening of the arterial walls, which may lead to ischemia, obliteration by embolism or thrombosis which causes softening in spots, and finally the rupture of arteries with all their concomitant symptoms

The next Congress will meet at Marseilles in April, 1899, the subjects selected for discussion are "Secondary Systematic Delirium," "Polyneuritic Psychoses," and "The Unrecognized and Condemned Insane"

PRAGTICAL NOTES

Lipoma of the Foot—Kleinknecht reports one case in the thirty two observations on record, in which the lipoma was mistaken for a sarcoma and the foot unnecessarily amputated, [illegible]t usually the diagnosis is unmistakable The treatment is [illegible] complete ablation of the tumor, which can be accomplished without a plantar scar, through a dorsal incision, if the metatarsal bones are spread wide enough apart —*Beiträge z Klin Chir*, xx, 2, *Semaine Méd*

Test Paper for Iodin in Saliva and Urine—A sheet of filtering paper is dipped in a 5 per cent solution of cooked starch When dry it is marked off into 5 cm squares, and in each square two or three drops of a 5 per cent solution of ammonium sulphate are dropped and dried, sheltered from intense light The ammonium sulphate loses its power in two or three weeks, it is best applied fresh To test the intestinal absorption let the subject swallow a glutoid capsule containing a little iodoform Then mark the hour on the first square, and number the rest The subject then deposits some saliva on the corresponding square every hour, and an exact record of the intestinal absorption is obtained, as the paper turns blue in contact with any traces of iodin —*Semaine Méd*, September 7

Iodin for Acute Gastro Enteritis—Iodin has been recently recommended by Grosch (Journal, page 302), and P A Bizine of Russia also proclaims its remarkable efficacy in acute gastro enteritis He administers to children with diarrhea or cholera infantum, a teaspoonful every hour, of the following Emulsion of castor oil, 180 grams, essence of peppermint, 3 drops, essence of cloves, 5 drops, tincture of iodin, 10 drops, chloroform, 2 drops The bottle must be kept on ice to prevent decomposition If a slight diarrhea persists after the contents have been taken, he gives two powders a day, in water, as follows Iodized starch, 75 centigrams For six powders The proportions are increased for an adult Emulsion of castor oil, 180 grams, essence of peppermint, 5 drops, essence of cloves, 7 drops, tincture of iodin, 15 drops, chloroform, 5 drops A tablespoonful every hour When the principal morbid symptoms have subsided—usually in twenty four hours—he gives 60 centigrams of iodized starch every four hours In cases of cholera nostras he administers the following at one dose Castor oil, 20 grams, essence of peppermint, 3 drops, tincture of iodin, 10 drops, chloroform, 2 drops, supplementing the medicine with an injection of tepid water if the purgative effect is not prompt, hydrochloric lemonade for beverage, mustard plasters on the joints to relieve cramps, and hot water bottles to keep the patient warm, completing the treatment with the iodized starch as above —*Semaine Méd*, September 7

Aseptic Catheterism—Dr C Mansell Moullin has given an interesting and practical paper to the London *Lancet* of September 10, on the subject of urinary fever at the beginning of catheter life and of aseptic catheterism He says of aseptic catheterism that it is one of the problems of modern surgery He has been called upon to deal with it especially in cases of which there has been a large amount of residual urine The following are the essential features of Dr Moullin's very successful measures All instruments must be disinfected first by boiling The hands, the prepuce and the skin of the penis must be cleansed as thoroughly with soap and water as if a surgical operation were going to be performed, and then sponged over with a solution of corrosive sublimate, 1-5000 The glands of the meatus require especial care An irrigating catheter is then introduced into the *fossa navicularis*, and this part of the canal is thoroughly washed out from behind with boric acid Then the catheter is pushed on into the deep part and the process repeated Finally, Melchior's double catheter is introduced and the urine drawn off In this way it is possible to obtain a very high degree of asepticity When catheters have to be passed at frequent intervals, the disinfection of the hands, penis and front part of the urethra will manifestly be never carried out each time At the outside it will only be done night and morning, and often one has to be content if it is done thoroughly once a day But catheters can be kept clean Those made for me, as smooth and polished on the inner surface as they are on the outer, will stand boiling day after day (if they are kept straight while in the boiling water and drained afterward) and continued immersion in boric acid without injury Each patient is provided with two glass catheter cases One of these is filled with boric acid lotion for instruments that have been used, the other provided with a rubber cork as well as a metal cap, is dry and aseptic These cases are so arranged that they can be hung up in the patient's wardrobe, out of sight and out of dust No catheter is used more than once a day As soon as a catheter is withdrawn from the urethra it is dropped into the case filled with boric acid solution and left there Once a day all the catheters are taken out, boiled for five minutes, and placed in the dry case until required The plan is not perfect and I have no doubt is capable of improvement, but it works fairly well with an intelligent private patient who can be made to understand the necessity of observing strict precautions Unfortunately they are not all intelligent, and in the case of a hospital out patient such a complicated plan is out of the question The best that can be done is to start such people as well as possible and hope that by degrees they will acquire a certain amount of immunity against the toxins they are are bound to absorb There is a little evidence to show that a certain degree of immunity may be acquired, but I am very skeptic as to its ever being sufficient in the face of a virulent growth, or when the bacterium coli is assisted by other germs such as the streptococcus and the proteus

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE, INCLUDING POSTAGE

Per Annum in Advance	$5 00
Foreign Postage	2 00
Single Copies	10 Cents

In requesting change of address give old as well as new location

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
No 61 Market Street (Occidental Bldgs) Chicago Illinois

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association Dr Henry P Newman 100 Washington St Chicago Ill sending him a certificate or statement that the applicant is in good standing in his own Society signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character intended for publication in the JOURNAL should be addressed to the *Editor* and all communications relative to the business of the JOURNAL proof sheet returned, or in regard to subscriptions should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings) Chicago

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL

SATURDAY, OCTOBER 15, 1898

STEREOCHEMISTRY AND VITALISM

The sensational presidential address of Sir WILLIAM CROOKES at the late meeting of the British Association for the Advancement of Science, beginning with a prophecy of the failure of the world's wheat supply and ending with what seemed at least an endorsement of or expression of faith in the theories of telepathy, was, it appears, not the only utterance of scientific facts or possibilities that is especially noteworthy and exciting The address of Professor JAPP of Aberdeen, in the Chemical Section, appears also to have at least stirred up comments, and forms the subject of a rather bilious editorial in the *London Saturday Review* His subject, which has its interest to medical as well as to scientific readers and to cultured laymen, was the proof of a distinct vital agency or energy as afforded by the facts of stereochemistry, or by the optical effects of the molecular composition of substances Many years ago PASTEUR, whose high standing as a chemist has been so eclipsed by his biologic researches that it has been forgotten, expressed the opinion that the molecular asymmetry of natural organic products was probably the characteristic that best established a natural line of demarcation between the chemistry of living and that of non-living matter This molecular asymmetry is shown by the power these products have of turning the ray of polarized light to the left or right—a property which, according to Professor JAPP, is not shared by any inorganic substance in its natural states So far as known, PASTEUR, it seems never changed his views on this subject, and, according to the Scotch professor, modern chemistry has developed nothing to invalidate them He, therefore, offers as a contribution to the literature of the vitalistic controversy a very elaborate discussion of the whole subject of the asymmetric arrangement of the atoms in the molecules of organic products, reviewing what investigations have been made, and coming to the conclusion that we have in this twisted or one-sided atomic disposition a distinguishing characteristic of natural compounds of vital origin He finds as a result of all the data obtainable, that when the asymmetrically arranged atoms of which the inorganic world is composed are acted upon by symmetric forces in such a way as to produce asymmetric compounds, the constant result is either to form pairs of enantiomorphous molecules (those in which the asymmetry of one counteracts that of the other), or similar pairs of atomic groups within the molecule, and in either case the result is the same—mutual compensation and optic inactivity The same, he holds, would be the case with symmetric matter interacting under the influence of asymmetric forces—supposing such to exist—provided that the latter are left to produce their effect unguided, and under conditions of pure chance His own conclusion from it all, stated in his own words, is as follows "The production of single asymmetric compounds or their isolation from the mixture of their enantiomorphs is, as PASTEUR firmly held, the prerogative of life Only the living organism, with its asymmetric tissues, or the asymmetric products of the living organism, or the living intelligence with its conception of asymmetry, can produce this result Only asymmetry can beget asymmetry"

It will be seen that the last of these three conditions of the formation of asymmetric compounds leaves a considerable margin of possibilities in chemic manipulation, and affords room for the possible synthetic production of any amount of organic substances It would seem even to hint the possibility of a new origination of vitality life producing life, not by direct propagation, but through the action of intelligence and intelligently directed manipulation of non-living matter Admitting this would be, in some respects at least, a long step toward the position of the anti-vitalists There is also some assumption, perhaps, in the statement that under no conditions of pure chance could an asymmetric compound be produced As an argument for vitalism in its common acceptation, therefore, Professor JAPP's address is not absolutely complete or convincing, while it is an interesting contribution and shows up very prominently one of the distinctions that exist in nature between living and non-living matter and their respective products

The anti-vitalists, how[illegible]r, are as d[illegible] as, if not more so than, th[illegible] nts, and [illegible] r of the editorial write[illegible] aturday [illegible] evidence of this [illegible] reaso accept his assumptions any more than those of anybody else, we need not admit it as beyond possible doubt that the disproof of spontaneous generation will be overthrown, or that all vital processes will be demonstrated to be mere chemic or physical ones It is more scientific to wait the absolute proof of such views before accepting them as correct, and in the meantime we have many puzzling problems to solve before we can legitimately adopt them If admitting that vital phenomena are yet in their essence beyond our comprehension and as yet unaccounted for by the known laws of matter, is accepting the theory of vitalism, then a vitalistic point of view is really the only scientific one to adopt

RENAL HEMATURIA

Hematuria may occur in disease of any portion of the genito-urinary tract It is usually considered that the farther removed the lesion from the meatus, the more intimately mixed the blood and urine, When renal affections are causative, then we meet with the best type of an intimately mixed fluid of blood and urine While local conditions of the kidneys, as stone, new growth, parasites are responsible for many cases of what might be called renal hematuria, general pathologic systemic conditions must frequently be held to account Such conditions as the latter occur in the various acute infections, in the anemias, in the hemorrhagic diathesis Putting aside for the present the consideration of the above causes, there still remains a large number occurring for the most part in chronic rheumatic affections, in gout and in atheroma This hematuria is explained by Musser as due to trauma We know that in rheumatic disorders, in gout and in the various gastric and nervous complications attending these diseases urinary salts are excreted in excess The excess of these salts explains the trauma on the grounds of mechanical irritation, and more or less blood appears in the urine To be sure the hematuria thus resulting is as a rule microscopic, but is none the less a hematuria, and it might be said here the constant drain produced may partly account in not a few instances for the anemic condition observed in these diseases and especially in neurasthenic states Musser, who has studied this question most closely, found in almost three thousand examinations of urine obtained from nearly two thousand patients, hematuria in 364 distinct individuals "In 250 of the patients with hemorrhage the presence or absence of urinary salts was noted Of these, in 90 uric acid alone was found, in 49 uric acid and other salts, in 17 oxalates alone, in 19 phosphates alone, in 4 oxalates and phosphates were found In 71 it was stated there were no salts" He also states that the patients who were reported as without salts in their urine were afflicted with other disorders that readily explained the hematuria In conclusion one other point established by Musser must be noted that in all the patients in whom renal stone was diagnosed (and in whom time showed the diagnosis to be correct), blood, though often microscopic, was an almost constant ingredient of the urine in all instances

OUR PROSPECTS AS A PROFESSION

It is so easy to prophesy evil, and easier still to believe it From the days of Jonah and Jeremiah to those of Mother Shipton and the Millerites, men have been fatuously ready to believe the future big with portents of disaster We appear to be morally certain of only two things one that the world is, the other that it is soon coming to an end We can not refuse to admit that the past has been triumphant, and the present fairly satisfactory, but the future! The "signs of the times," whether religious, political or professional, are invariably baleful, and we can not help believing that a little of this pessimism is tingeing the vision of the prophets within our own ranks, in respect to the future outlook of our profession

Never was the outlook so gloomy, we are told, all the stars in their courses are fighting against us First of all the profession is overcrowded already to the starvation point, and a flood of hungry graduates is poured into its ranks every spring Then the dispensary abuse has reached such monstrous proportions that two-thirds of our population get their medical attention for nothing Next to this is the eye of jealousy, and only charlatans can succeed Finally—and most fatal of all—we are nobly but mistakenly destroying our own livelihood, sawing off the bough that supports us, by preventing disease so efficiently that ere long there will be none of it left for us to cure

That there is some truth in every one of these allegations it would be foolish to deny, but that all of them together are competent to bring upon us half of the injurious results so freely prophesied is utterly unproven, and, we think, can be shown to be improbable First of all, the general statement can be made in regard to all of them, that things are no worse in any of these regards now, than they were fifty or even a hundred years back with the exception of the hospital and dispensary abuse This is particularly true of the first count in the indictment Two generations ago there was exactly the same cry about "overcrowding" that we hear today, and it has turned out just as it did in the celebrated case of Malthus A century ago that renowned economist declared that our population was the root of all evil, and that the slightest increase upon the existing density would mean the ruin of the English race Since then the population of the island has quadrupled, and instead of its condition having been made worse by the change, it is far better than ever before—less crime, less pauperism, longer lives, lower death-rate, more meat, sugar, fruit, etc , eaten per capita than ever before in history, more money in the small savings-banks, higher wages, lower taxes, and our professional MALTHUSES have been equally stultified So far from being ground down by competition into poverty and discredit, never was the doctor better paid, better equipped, better dressed and housed, and best of all, more respected and more trusted than he is today If any one doubts the latter let him take one glance at the literature of the past century and a half and see what figure the doctor cuts in it Previous to GEORGE ELLIOT's "Lydgate" there is scarcely a medical man mentioned in English fiction or drama without a sneer or a slur, "the doctor" is invariably a pompous fool, a shrewd old ignoramus, or a whining cheat Look at the fawning cads and impostors of SMOLLET, FIELDING, and MOLIERE, of DICKENS and THACKERAY, and contrast them with BALZAC's medical hero, and with that highest compliment and noblest tribute ever paid our profession—"Maclure of Drumtochty, and whichever way we turn we find the same sort of contrast between now and then in fact, it can be abundantly proven that the marked increase of the already "overcrowded' state of the profession in the past seventy years has been attended by no deterioration. but on the contrary, by a great improvement in our condition and status

And the same contrast can be seen between different countries at the present day In 'density of doctors, the United States heads the list with one to every 600 of her population· then comes England with about one to 1500 then Germany with one to 4000, and finally Russia with one to 7000, and Turkey mate fees caused thereby That this is an evil and a serious wrong alike to the profession and the laity is unquestionable, but that it has so far done any serious injury to the profession as a whole we utterly deny In the first place, from the medical point of view, its injustice lies, not in robbing the profession of its financial dues, but in unequally and unfairly distributing those dues in the interests of the more "pushing" and dramatic individuals, at the expense of the more modest and less distinguished There can be no question that it "pays" well on the whole and in the long run, or there would not be such an eager rush for positions of any sort upon its staff, and as the practice of medicine is supporting nearly twice as many physicians as ever before, it can hardly be fairly said that any considerable proportion of the profession is *absolutely* injured thereby, although it may be *relatively* In spite of many striking and disgraceful exceptions, the vast majority of those who attend our dispensaries are so much "clear gain,' so to speak, to the profession, as they would otherwise never have employed *any doctor*, except the county or parish physician, either from ignorance, prejudice or unwillingness to pay the fee, and the formation of the "doctor habit" in these large classes is worth, financially, ten times as much to the profession as any possible loss of fees from the small percentage of really probable "pay patients" among them This consideration is one which, we think, is hardly given its full value in discussing "hospital which sweeps through the minds of all the less intelligent classes We are gravely suspected of "experimenting" upon our patients, of "giving medicine to keep one sick," of rejoicing in the spread of epidemics, and even of such insanities as hastening the end of hospital patients to get their bodies for dissection, or of performing gruesome operations for the purpose of securing certain portions of the viscera to use in making medicine The celebrated "Whitechapel murders" were firmly believed, in the locality itself, to be the work of a doctor who was determined to have fresh, human kidneys for some such purpose, and this precious theory was actually exploited in some of the daily papers, whose sapient reporters declared that the shocking mutilations of the victims was evidently the work of a "surgical hand"

In short, both these large classes of the community have to be educated up to using the doctor, as they have to take a weekly bath, and their reluctance is due to something the same queer mixture of economy and distrust in both cases

With all its abuses, the free dispensary has done and is doing us yeoman service with these large masses of the laity, teaching them by actual experience that the doctor is a necessity instead of a luxury, a good investment instead of an extravagance, a true and valiant friend instead of an enemy and a heartles *exploiteur*

Last of all, what of the danger that by our vigorous and successful championship of sanitary reforms—a championship whose sincerity and devotedness not even our enemies have ventured to impeach—we are actually closing our own field of labor, destroying our own hopes of a livelihood? It need hardly be said that we are not raising this question with any reference to the advisability of continuing such a course of conduct Any such suggestion would be even more futile, thank God, than contemptible, for we are unalterably pledged to mortal and relentless warfare against disease and pain in every form, and by every weapon suggested alike by our ancestry and our interest as physicians and as men And even should such a course ultimately result in the complete extinction of our craft from lack of occupation, we would be the first to hail the event as a blessing to humanity and seek other less saddening and certainly not more arduous occupations

The question simply is Do the sacrifice and laborious services of the physician in behalf of the public health result in impairing his own chances of earning an honorable and adequate livelihood? If we put the query in the past tense it answers itself at once As everyone at all familiar with vital statistics knows, the number of physicians supported by any country and the adequacy of their support is in exactly inverse ratio to the mortality and morbidity rate, from Turkey with its one physician to 9000 and its death-rate of 70 per 1000 per annum, Russia with 1 in 7000 and a death-rate at 50 per annum, up to England with her 1 to 2000 and death rate of 16, and the United States with 1 to 600 and a death-rate in some cities as low as 9 In fact, paradoxical as the statement may appear, the countries which have the most sickness support fewest doctors, and vice versa, those which have most doctors have least sickness

Nowhere have sanitary measures diminished the demand for physicians one iota, but rather, the higher the standard of health has risen, the keener the request has become for that most efficient and only agent for its attainment—the family physician Instead of being in danger of extinction he is barely at the threshold of his full usefulness to the human race A very large proportion of even our most highly civilized communities avail themselves but little of the services of the doctor save in mortal or serious illness The realm of what might be termed "personal preventive medicine" is only just opening up to us Get rid of the old and irrational method of summoning us only in disease and too often long after hopeless mischief is done, and let us be engaged by annual compact to keep our families in health, instead of simply curing them more or less imperfectly when ill, and we could profitably devote our entire time to the care of less than half the clientèle which at present we are attempting to care for, and the benefit to the race would be enormous

Contrary to popular impression and legend, the race is improving physically every century, and men's standards of health are rising just as their standards of living and of morals are The more efficient our sanitary precautions and the wider the spread of hygienic knowledge among the people, the higher and more exacting does this standard become The intelligent Englishman and American of today would be no more satisfied with the standards of health, comfort and bodily efficiency of the citizen of the Middle Ages than he would with the latter's rancid undergarments, stinking floors, unglazed windows and filthy streets What his ancestor called a trifling running of the nose or huskiness of the voice, and expected to put up with his life long, he dubs "catarrh," and insists on having it cured A deformed arm or leg, instead of being endured as a dispensation of Providence, must be cured or else amputated and a rubber one substituted, his sight must be perfect and his head free from aches, or lenses are at once demanded, and so on all along the line It is not that disease has increased—far from it—but our toleration of it and of discomfort or inefficiency in any form has greatly diminished

So that while, three generations ago, there was simply one doctor in the town or even county—to be called, with the priest, only in cases of mortal urgency—there are now ten family advisers and a dozen specialists of every sort needed to meet the higher demands of the community for "Health, more

Health" And when we further remember the numerous official avenues of usefulness which sanitary progress has opened up to physicians—such as that of health officer, the board of health, the sanitary inspector of factories, of mines, of schools, the railroad surgeon, the insurance examiner, the food inspector and a score of others—we can readily see not only why the diminution of endemic disease has not limited the field of activity of our profession in any way, but on the contrary, immensely widened it, but also that there is no prospect of its doing so for generations to come Half of our present membership could be profitably employed in studying and supervising our schools and systems of education alone, and in less than a generation more the school physician will be considered as necessary as the teacher or superintendent

In fine, our ideals already rise faster than our attainments, in hygiene as elsewhere, and there will ever be a broad field for honest, conscientious workers who are willing to assist in their realizations Our prospects as a profession were never brighter and more hopeful than they are today

MEDICAL SIGNERS OF THE DECLARATION OF INDEPENDENCE

A recent article in a magazine has claimed that the vast majority of the cultured people of what are now the United States were opposed to the movement for independence from Great Britain It is difficult to see on what data this claim is based, since a fair estimate of the position of people of culture can be formed from their number in the Congress which drew up the Declaration of Independence A decided majority of the signers not only had what would now be a high school education, including Greek and Latin, but several were prominent in the science and literature of the time Many graduates of universities were elected to and took part in the formation of the Declaration of Independence Five were physicians, not only prominent in public affairs but in science and general literature as well Drs Josiah Bartlett, Matthew Thornton, Oliver Wolcott, Benjamin Rush, and Lyman Hall, were five physicians who signed the Declaration Dr Josiah Bartlett was a descendant of an English family, whose founder had entered England with William the Conqueror and had been ennobled by him The founder of the American family settled in Massachusetts in the 17th century Dr Josiah Bartlett was born in Amesbury, in November, 1729 Albeit, not a college-bred man, he became an excellent Greek and Latin scholar The literature of these languages remained a favorite study until the close of his career At sixteen he began the study of medicine, as an apprentice of Dr Ordway, a distant relative of the family This apprentice system prevailed in New England until the beginning of the 19th century After the completion of his medical studies he settled at Kingston, N H, as a practitioner He gained a reputation even beyond the bounds of the State for his success in the treatment of malignant diphtheria, then called "black canker" The treatment he adopted in this disease was practically that of the present day, other than the orrhotherapy He employed local anesthetics, chiefly essential oils, and mecurials The patient at the same time was supported by nourishment in fluid form and stimulants As the Bartletts had imbibed the republican principles of the English Puritans, who founded the British commonwealth, it was but natural that one of their scions should take an early stand for representative government The standing of Dr Bartlett in the community is shown in his appointment as a civil magistrate, and as a colonel of a regiment of provincial militia, by the royalist governor, Benning Wentworth In 1765, Dr Bartlett was elected a member of the provincial legislature He was foremost in the opposition to the corrupt, tyrannic system pursued by Governor Wentworth In violation of the principles on which New Hampshire had been settled, and in violation of the religious rights of the settlers (the vast majority of whom were Puritans), Governor Wentworth attempted to establish a State church In the endowment of this he reserved lands belonging to the public Foremost in opposition to such procedures was Dr Bartlett, who, in 1774, led the movement to choose delegates for the Continental Congress, which met in September 1774 Dr Bartlett was chosen a delegate thereto, but was unable to attend, on account of his house having been destroyed by fire Because of his movement against British tyranny, Dr Bartlett was dismissed from his military command and his commission as a magistrate annulled In August, 1775, he was chosen a member of the Continental Congress, and was foremost in its deliberations In 1776, being reelected, he became a member of the committee which devised the articles of confederation, under which the United States were ruled until the adoption of the Federal constitution, in 1788 After the Declaration of Independence had been discussed and was laid before the Congress for adoption, Dr Bartlett was the first to vote for, and the second to sign it John Hancock, being president of the Congress, first signed the document In 1777 he was reelected to congress, but was unable to attend, because of ill health In 1779 he was elected chief justice of the court of common pleas and was also made mustermaster of the troops then being mustered in for the continental service In 1785 he became a judge of the state court In 1788 he was promoted to the office of chief justice of the supreme court He was an influential advocate of the federal constitution in the convention of New Hampshire In 1788, when that went into operation, he was elected a senator in the first Congress under it but declined In 1790 he was chosen president of New enthusiastic, most appreciative, and most laudatory letter to JENNER after some years' trial of vaccination in Virginia The logical nature of JEFFERSON'S mind, his deep regard for the rights of individuals, and his scientific acumen render this letter a most emphatic demonstration of the falsity of the antivaccination cant As Dr CALDWELL has shown (History of the American Declaration of Independence), every one of the fifty-six delegates who signed the Declaration of Independence were men of well-balanced and well-cultivated minds Of them, two died of accidents in the prime of manhood The other fifty-four averaged sixty-six and three quarter years—an illustrious example of the influence of well-cultivated and regulated brains, WINSLOW remarks, in conferring longevity upon those who possess them Several of these delegates lived beyond their eightieth and some of them to their ninetieth year The medical members averaged seventy-one years each The history of the Declaration of Independence, therefore, demonstrates that since the stream can not rise above its source, the cultured people of what are now the United States took an active part in establishing, permanently, the principles of constitutional liberty which the colonists had inherited from their English speaking ancestors This is further shown by the great proportion of physicians and scientists among the signers When commercialism and demagoguery are dominant, the medical man is regarded as unfit for the "business" end of politics When culture, common sense and public spirit without the plutocratic taint are uppermost, the physician always comes to the surface as an ideal representative

CLAUDIUS HENRY MASTIN, M D

CLAUDIUS HENRY MASTIN, M D, University of Pennsylvania, 1849, died at Mobile, Ala, October 3, aged 72 years He served as a surgeon in the Confederate Army and was a member of several scientific bodies

In the death of Dr MASTIN the medical profession has lost one of its most learned and active members The American Surgical Association will miss him, and the Alumni Association of the University of Pennsylvania is deprived of one of the ablest and most efficient workers for the University A loyal friend, a gentleman and a scholar, his life is now only a sweet memory, but his surviving friends will cherish it while they remain on earth as an undying possession

CORRESPONDENCE

Case of Fetal Monstrosity—Thoracopagus

WEATHERLY, VA, Oct 6, 1898

To the Editor —July 15, 1898, I was hastily summoned to the bedside of Mrs ——, a primapara, who presented the following history She had been greatly molested by pains in the abdomen, principally during the night, for about a fortnight During the night of July 15 she was startled by a sudden gush of liquids, which was none other than the amniotic fluid, and apprising her mother of what had happened, a messenger was sent for me Arriving at her bedside I discovered her with a severe intermittent pain, characteristic of labor Washing and disinfecting my hands, I proceded to make a digital examination to ascertain the cause, since the woman declared to be only six months pregnant I found the os soft and dilatable, and a fetal foot presenting

Firmly grasping the presenting part I applied gentle traction, and presently I had what I presumed to be the mate to the foot presenting, but noticed the singularity of both feet facing each other On high examination I was positively convinced that they were not members of the same body My next procedure was to replace one foot and bring down the mate, but my efforts at this were futile I however, brought down a third foot, and mating them, I attempted replacing the odd member back into the uterine cavity by gently pulling and simultaneously pushing back the one foot No success in these manipulations, inasmuch as my pulling perceptibly affected the other foot I now began to search cautiously for the missing fourth This was not an easy task, because by this time the expulsive pains and efforts of the woman were very severe After much patience I ultimately located it and succeeded in hooking my index finger around the groin, forcing it down I must admit that I now had on hand an experiment which embarrassed me not a little, but gave no vent of it, so worked zealously on as my judgment suggested Grasping the handful of feet with one hand while I busied the other in supporting the perineum and "shelling out" I had the two bodies down to the axilla I now had the satisfaction to take *stock account*, as it were, and found that I had not only twins to deal with, but that they were closely joined together from the umbilicus on up as far as I could find I shook off all remnants of perplexity at this point, knowing full well, however, that the problem was not solved Gentle and patient manipulations delivered the arms and shoulders As every accoucheur will readily perceive I now had arrived at the climax or trying point—to deliver the heads This was accomplished with apparent ease I gently rotated the bodies so as to present them obliquely, to have advantage of the largest diameter of the maternal pelvis By external pressure and traction, and encouraging the woman to bear down forcibly, I had the satisfaction to feel the lower head yield, and by swinging the bodies forward at right angles to the woman it was soon in the sacral cavity, the other head following in the same manner Rotating the bodies now so that one head should rest against the perineum, the other against the pubic arch, and still holding at right angles, the complete expulsion was ultimately effected, and this, without the use of an anesthetic, no damage to the soft parts The placenta was delivered with ease, and the subsequent history of the case uneventful

The placenta was normal in size—one common umbilical cord and near the placental insertion was a large clot of blood which had the appearance of being several days old, and undoubtedly created the pains and also precipitated the labor, as well as a providential interference to rectify a mistake of nature Had the woman arrived at full term of gestation a difficult and serious labor would have been inevitable Now a brief description of the product of this labor The double monstrosity was 12¾ inches long and weighed six pounds Both fetuses were well developed and symmetrical, of the male sex, and united together along the sterni clavicular articulation to the umbilicus The possession of it was denied, much to my utter disappointment since I very much desired it The union was very close, and not only tegumentary but evidently the two sterni were cemented together without any communication of the thoracic centers They were dead *in utero* probably three or four days and showed evidences of maceration

Playfair's work on Obstetrics quotes nineteen cases of similar nature but the presentations differed

I have thus modestly recited my procedure and success in this rare case, and I report it not with a view of expecting to call forth praise and admiration for terminating a case of such extraordinary character, but with a hope that by reporting this to the professional fraternity some brother may escape the embarrassment which confronted me, as well as to be instructive to the readers of this valuable JOURNAL as it has been to me

W P LONG, M D

Complete Congenital Separation of all the Bones of the Cranium

FLORENCE, COLO , Oct 8, 1898

To the Editor —Recently I attended a lady in confinement, who gave birth to female child at term—presenting such a remarkable and unusual anomaly of osseous development—that I herewith hand you the details, in brief, for publication The fetus presented by the occiput and nothing unusual was observed till the head engaged in the vulvar outlet, when great mobility was apparent to the touch After delivery, which was normal—assisted by traction with the hand only—all the cranial bones were found to be completely disunited at their sutural lines *Not one* was united with its fellow, and in the case of the frontal bone, the two halves were ununited as in very early fetal life No union anywhere had ever existed, although the individual bones were perfectly formed, and when held in proper position in the hands, made a cranium of normal shape and size In fact, after delivery of the head from the outlet, there was not much displacement with the head lying at rest, the bones seeming to be held in relatively proper position by the connective tissue underlying the scalp The scalp itself was normal, not perforated or broken at any point, and manipulation of it gave the impression of a bag or sack containing separate bones loosely attached to its inner surface, which was in fact the case The fetus was dead, and from appearances had been so for several days The mother felt "motion" last about three days previous to the onset of labor, which was slow and prolonged by reason of the conditions set forth

There was nothing remarkable about any other portion of the osseous system, the child was well developed, and would, perhaps, have weighed eight or nine pounds The parents are healthy, and there is no history of any constitutional taint or dyscrasia on either side The mother has aborted twice—once at four and a half months, once at seven and a half—the only times, save this last, of pregnancy

An interesting circumstance connected with the case is the fact that *each parent was a seven months' child* What rôle, if any, this circumstance may have played in the case, I will not attempt to say I was unable to procure the infant for dissection and preservation of specimen, much to my regret In a careful search of all the literature at my disposal bearing upon anomalies and monstrosities, I have been unable to find a similar case, and in an experience of a quarter of a century I have not before seen anything approaching it

Since its rarity makes it extremely interesting, I publish it, hoping that if any one else has seen a duplicate, he or she, will do the same Yours,

B ROSEBERRY, M D

P S —The condition was not due to hydrocephalus

Disease of Intemperance

NEWARK, N J , Oct 4

To the Editor —In your timely article on ' The International Temperance Congress," in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION (Oct 1, 1898), you well say, "[illegible]es tions concerning the action of alco [illegible] riety and prevention, are vital in alm [illegible] bor

[illegible] land, and it would seem to be a most practical subject for medical men to discuss and study," for physicians preeminently possess the power to arrest and prevent the spread of the disease of intemperance They alone can prohibit with authority the use of alcohol in the nursery, hospital and general practice, and so prevent the acquirement of the appetite for alcoholic drinks—slowly induced in some, in some more rapidly—which, Tantalus like, torments and devours the sufferer with a perpetual thirst

According to the best authority, experience has demonstrated it to be a fact that as regards the drink habit, the first step in an attempted reformation must be the removal of the appetite, and nothing will do this but an entire abstinence from its provocative and inducing causes

Undoubtedly, opium and alcohol produce effects which differ, but they agree in this that used habitually, they alike tend, by a law as constant as gravitation itself, to establish a tyranny compared with which chains, racks, dungeons and whatever else go to make up the material apparatus of the most cruel despotism are as nothing, for these are outside the man and leave the soul untouched

Christianity is a principle not a law , Christianity is Christian love This fulfills all claims, abstinence among the rest

Respectfully,

J ACKERMAN COLES, A B , A M , M D

Hygiene of Music

MINNEAPOLIS, MINN , Oct 2, 1898

To the Editor —A medical friend having called my attention to your interesting article on "The Hygiene of Music," in your issue of September 24, I beg leave to offer a few suggestions in amplification of your remarks

The question as to whether music appeals exclusively to the emotional appears to be mooted rather one sidedly In music, as in any other field of education, we do not make a sufficiently clear distinction between appreciation and creation Waiving the discussion as to whether the excessive indulgence in either branch (I use this expression for want of a better one) must needs result detrimentally to the individual, I desire to call attention to the fact that when the intellect is to be employed, there is a vast difference between a mere indulgence in rendered music and the execution of music Your esteemed colleague, the recently departed Dr Billroth at Vienna, has left quite extensive notes on music, which were edited and partly published by Eduard Hauslick, the noted Vienna musical critic, in a little pamphlet under the title "Wer ist musikalisch? ' (first published in the *Deutsche Rundschau*, Vol xxii, Berlin) Among other interesting statements, Dr Billroth emphasizes the fact that the practice of music draws upon the intellectual powers To be sure, not in the degree required by the study of Greek, mathematics or the playing of chess, but nevertheless a sufficient call for intellectual activity The student of music, says Billroth, must have "*die Freude an der Ueberwindung von Schwierigkeiten*, that is, "the joy of over reaching difficulties " To this it might be answered that the riding of a bicycle requires the exercise of the same faculty, and yet this should not be called an intellectual employment According to Gladstone (although an axiomatic truth independent of any authority), the safest recreation is a change of employment Bicycle riding, it will be admitted, draws less upon the intellect than the solution of a mathematical problem, yet the powers of quick decision, discrimination, etc are more or less needed in pushing your wheel through a crowded thoroughfare Now, in practicing music, the same, and vastly more, is [illegible] me take, f [illegible] p [illegible] study of the violin

You [illegible] or [illegible] you can

hold

you

can and must get it solely by repetition is now a days discarded by advanced teachers They know that your hands and fingers are directed from the nerve centers in the brain, and accordingly they practice with the "head" and not with the "fingers" And, recurring for a moment to the bicycle A tall, strappy Swede, whom I entrusted with the ennobling task of cleaning my office, remarked that he thought he had to give up the attempt to ride a wheel, "he would never get it" "I presume you are riding it with your legs and feet?" I queried He looked foolish "Well," I said, "you must ride it with your head"

The independence of the fingers in violin playing is a matter of progressive education The fingers of a violin artist are not more fit to exercise a particular employment, requiring dexterity of the fingers, than the fingers of a rapid stenographer or typewriter are for violin playing Even the much praised "limbering up the fingers" is of but limited account in the handling of a musical instrument "Cheiro," the palm reader, notwithstanding his charlatan platitudes, has it correctly when he asserts that pliable fingers are unfit for music, and that "educated fingers" are essential The strict observance of the time (tact) in ensemble playing, certainly calls for intellectual alertness, quickness of perception, and independence of thought from mechanical labor The trained musician reads half a dozen bars ahead while he is playing with "feeling" (*natural or artificial*), and at the same time watches the baton of the leader

Another very important function in connection with musical execution is the memorizing of music pieces This is now done by impressing the image of the musical characters (notes, etc), upon the mind, against the obsolete method of thoughtless repetition The great German violinist, Burmeister, some time ago, performed the feat of memorizing a new, difficult piece while riding in a railroad car, by looking it a few times over He played the bulky concert from memory without missing a single note, or the prescribed shades of forte, piano, etc , so brilliantly that the uninitiated would have sworn this to be the result of mastery gained by many trying repetitions

ARTHUR L HERMANN
Counselor at Law

A Defense of Dr Huidekoper

WOODBURY, N J , Oct 6, 1898

To the Editor —In the *Medical Record* of Oct 1, 1898, there is a short editorial *in re* Prof Rush Shippen Huidekoper, that is so unjust to the man, so absolutely devoid of that *camaraderie* usually characterizing the intercourse of medical men that I ask space to reply to it *It should be all sufficient for a writer in a journal supported by doctors that a man holds a diploma from a reputable school and is himself in good professsonal standing* That he has devoted a number of years to the study and teaching of comparative medicine should not, I take it, be a bar, but rather a recommendation, for any preferment to which he may aspire, or which (as in this case) may be tendered to him These ethics of the *Medical Record* are the ethics of "kites and crows," and should be promptly and unmistakably disavowed by the profession If the only objection to Dr Huidekoper lies in his title of M V Alfort, it would not perhaps be unwise for more of his profession to improve their minds by the attainment of a like disqualification Respectfully, T B ROGERS, D V S

SOCIETY NEWS

American Academy of Railway Surgeons—The following officers were elected for the ensuing year President, W W Grant, Denver, first vice president, T F Pritchard, Manitowoc, Wis, second vice president, J P Lord, Omaha, secretary, T B Lacey, Council Bluffs, Iowa, treasurer, C B Kibler, Corry, Pa , editor, Fred J Hodges, Ashland, Wis Place for holding the next meeting, Omaha, October, 1899 Committee of arrangements J P Lord, chairman, T B Lacey and Fred J Hodges

Western Surgical and Gynecological Association—The eighth annual meeting of this Association will be held at Omaha, Dec 28 and 29, 1898 The local Committee of Arrangements at Omaha is actively preparing for the entertainment and comfort of those who attend Surgeons and gynecologists, and those interested in the progress of these specialties, are cordially invited to affiliate themselves with us The secretary will be glad to send application blanks Titles of papers should be sent to the secretary as soon as possible, but not later than November 20 to insure a place on the program Geo H Simmons, Secretary, Lincoln, Neb

Association of "Big 4" Railway Surgeons—The next meeting of this Association will be held in Cincinnati, November 10 The program includes the following papers

The Diagnosis and Treatment of Lumbago and Back Sprain, J Schneck, Mt Carmel, Ill

The Surgical Consideration of Shock and Its Treatment, A Rhu, Marion, Ohio

The Value of the Hot water Bath in Surgery, T P Satterwhite, Louisville

Address of President, L E Russel, Springfield, Ohio

The best Method for Examining the Eyes and Ears of Applicants for Admission to the Railway Service, C W Tangeman, Cincinnati

The Care of Head Injuries, Webb J Kelley, Galion, Ohio

Report of a Case of Brain Injury, T J Whitton, Nokomis, Ill

The Railway Surgeon and the Company, Geo M Waters, Columbus, Ohio

Hemorrhoids and Their Treatment in Railroad Employes, T M Kyle, Aurora, Ind

Anesthetics—How to Minimize the Danger of Their Use, E H Hyatt, Delaware, Ohio

San Francisco Medico Chirurgical Society—At the meeting for October, Dr Rigdon gave a very interesting demonstration of the instrument devised by M L Harris of Chicago (*vide* JOURNAL, Vol xxx, p 236) for obtaining the urine from either kidney, unmixed The apparatus, as is well known, consists of a double catheter of special form and construction, and of a second instrument, to be introduced into the rectum in men, or the vagina in women, so formed that when in place it will make a ridge along the longitudinal diameter of the bladder The two parts of the catheter are then rotated downward so that one section is on either side of the ridge thus formed If the bladder has been evacuated and washed before the introduction of the catheters, the urine will be drawn from the two sides unmixed, and the condition of the secretion of the two kidneys may then be compared After calling attention to the often almost vital importance of being able to thus differentiate the two kidneys, as to the character of their secretion, Dr Rigdon introduced a patient and proceeded to demonstrate the facility with which the instrument could be introduced and the urine obtained The greatest advantage which this apparatus possesses is that it may be used by any one not equipped with the great manual dexterity required for operating the cystoscope, and also this apparatus may be used in cases where the cystoscope is not available, on account of the abnormal position of the ureters or from profuse hemorrhage or some similar reason The bladder being empty, great care must be exercised in rotating the two catheters after their introduction into the bladder, for the reason that it is very easy to injure the bladder walls The demonstration was eminently satisfactory, and the members present were able to see for themselves both the ease of introduction and the rapidity with which the secretion of the two kidneys could be obtained and examined The patient complained of no pain or distress and seemed not to object in the slightest to the manipulation The curious fact was noted by several of the members that the rate of secretion did not appear to be the same for both kidneys, the right secreting more urine in the time of observation than the left Dr Rigdon expressed it as his opinion that this difference was more apparent than real, as he had noticed that in the course of a little time the other side would in turn secrete more and thus keep the two sides about the same Dr F B Carpenter suggested that an enlarged prostate might interfere with the proper adjustment of the curved catheters and thus prevent the proper application of the apparatus Dr Lane, in discussion, said that he was personally acquainted with two cases where the wrong kidney had been removed by mistake, one of the cases he had himself operated on, and in the second case he had been present at the operation, he therefore called attention to the great importance of differentiating the two kidneys in cases where there was evidently kidney disease but where the exact location of the affected kidney could not be ascertained by palpation or examination It was his opinion that the device under discussion promised well, and he would await further reports as to its efficiency in actual practice, with much hope for favorable reports

PUBLIC HEALTH

Tropon – This new cheap preparation of albumin, recommended as food for the masses (vide JOURNAL, xxx, 1304), is warmly endorsed by D Finkler of Bonn, after long and extensive tests It contains almost pure albumin, is well absorbed, and can be taken for months, even years, in various ways —*Munich Med Woch*, August 23

Hygiene for Children —The recent death of an eight months' child whose head was caught between the side bars of its iron crib, suggests the necessity of furniture better adapted to children How many unnecessary injuries would be avoided if for instance, sideboards, commodes, etc, were made with rounded instead of sharp corners '—*Gaz Méd de Paris*

Culinary Bacteriology —Jager of Konigsberg has been delivering a popular course of lectures on hygiene and bacteriology, in which he has applied laboratory methods to culinary matters and processes His jars with cotton stoppers like culture tubes, filled with cooked and uncooked meats, etc, kept unspoiled from five to fifteen days in the warm hall —*Journal de Hygiene*, September 15

Albumose Milk —A cheap and easily prepared modification of milk for infants has been prepared at the Gottingen University clinic, which has produced excellent results in the infants fed with it to date It is based on the fact that albumose will hold casein in an emulsion and cause it to be precipitated in fine flakes, very much increasing its digestibility They dilute cow's milk with water, add cream and sugar of milk, and finally a certain amount of caseose (casein albumose), according to age of the child —*Deutsche Med Woch*, August 11

Alcoholism in Russia —According to the *Progrès Médicale* of September 17, the authorities of the city of St. Petersburg have suppressed the 25,000 saloons where alcohol was sold, and established in their place 5000 shops under their control scattered a certain distance apart all over the city The alcohol is all tested and sold in bottles of a certain size, not large, sealed with a government stamp No one can purchase more than one bottle at a time in one of these shops and he must walk a considerable distance before he can obtain another, which is absolutely refused him if he shows the slightest indication of drunkenness

Parasites in Game —Megnin reported recently to the Paris Académie de Médecine that he had noted an epidemic among pheasants last year, caused by a tenia, and that he has found the same parasite again in partridges this year His investigations were made at Gueville where the game is raised in large numbers, and over 300 died last year He therefore names the tenia, Davainea Guevillensis, as it differs from the others known The *Bulletin*, September 13, contains descriptive cuts The parasite obstructs the intestines by its size and numbers, hundreds often being found in one bird

High Mortality in Chili —We notice in an article on the sanitation of Santiago in the *Revista Chilena*, that the death rate in Chili from 1885 to 1889 was 30 3 per thousand, and from 1892 to 1896, 31 2 The number of illegitimate births is also high in England the proportion is 1 to 13, while in Chili it is 1 to 3, and during the first quarter of the present year, 1 to 1 3 The natality is larger than in other countries, 45 per thousand, in Germany it is 40, England, 36 and France, 26 The infant mortality is correspondingly high, 37 74 per cent in Santiago

Contagion Among Nurses —Cornet states that two thirds of the members of the religious sisterhoods who work among the sick, die of tuberculosis Rumpel reports 114 cases of disease with 10 deaths, among the 300 nurses employed in the Hamburg hospitals, and 43 deaths among the 2349 nurses in the eighteen Red Cross hospitals in Germany, seven from typhus and sixteen from other infective diseases, during the last three years The total number of cases of disease acquired professionally amounted to 640, including 56 cases of typhus, 53 of diphtheria, 15 of scarlet fever, 6 of measles, 20 of wound infection and 118 of various forms of angina —*Vienna Klin Woch*, September 15

International Quarantine Service in Egypt —This service, established by the International Health Convention at Venice in 1892, now comprises an inspector general with a salary of $3,000 to $3,600, seven superintendents of the sanitary stations Alexandria, Port Said, Suez, Tor, Damietta, Souakim and Kosseir The salary of the first four is $2,400 to $3000, of the rest $1,200 to $1,500 The Tor station is not occupied except during an epidemic, the incumbent residing at Alexandria Besides these there are six quarantine officers with a salary of $1,600 to $2,400, with an indemnity when they are sent to Tor A laboratory for bacteriologic research has been established at Suez, and all the members of the service must be thoroughly trained and experienced in medicine and practical bacteriology with a knowledge of French, German and English at least The various nations interested are all represented, France with four, which includes the inspector general —*Presse Méd*, September 14

Yellow Fever —According to press dispatches since our last report (vide JOURNAL, p 868), the conditions in the South are as follows The total cases number 465 in Louisiana for the summer, with 30 deaths, and 351 cases in Mississippi with 35 deaths, 44 cases occurring in Jackson from September 27 to October 8 In Louisiana the distribution of cases reported to October 8 has been New Orleans, 62 cases, 11 deaths Harvey's Canal, 14 cases, 3 deaths, Franklin, 210 cases, 7 deaths Wilson, 247 cases, 4 deaths, Baton Rouge, 22 cases, 2 deaths, Houma 8 cases, 1 death, Clinton, 2 cases, Plaquemin, 3 cases Jackson 22 cases Bowie, 1 case

In the following parishes (outside of towns above mentioned) cases were reported Iberville parish St. Charles parish St James parish East Feliciana parish West Feliciana parish, Rapiden parish (Alexandria) East Baton Rouge parish On October 8, Hattersburg Miss, reported 20 new cases Jackson 10 Natchez 2 Madison 3 Starkville, 1 Fayette, 2, Hermanville, 1 Taylor's Station 1 Harriston, 1 Oxford 2 and 1 death The reports for October 9 add Poplarville, Miss, with 2 new cases, Lumberton, 2, and 7 new cases at Jackson October 10 reports give Canton, Miss, 3 new cases, Crystal Springs, 2, Waveland, 3, all towns hitherto uninfected

Smallpox in a Summer Hotel—It is not a pleasant event for a busy summer hotel to have to shut up in August or September, on account of an infectious disease among its guests or servants,-especially so when the proprietor knows or is told that the trouble and loss might easily have been prevented This remark applies with special force to smallpox Why would it not be a good standing rule for hotel people to refuse to employ waiters and helpers who have not the evidence of a recent and successful vaccination? The recent experience at a large house, accommodating several hundreds of guests, recites the old, old story of the first cases of variola being mistaken for varicella The mistake corrected itself, after a short delay, and this correction emptied the house Fortunately every effort was made to prevent the spread of chicken pox, while the disease was yet thought to be of that nature, but not soon enough to prevent exposures, in greater or less numbers Late in August the correct diagnosis was made and the usual preventive measures begun There were several hundred guests at the hotel, on August 28, who left on that day, scattering to the four points of the compass Twenty six cases of the disease, all among the servants of the house, were reported Of these twenty one were among the colored help, and nearly all of these hailed from Asheville, N C, in which State not a few cases of smallpox have occurred since January last There was one death The hotel was closed and no new cases have been reported since the quarantine was established Hotel reputations are so susceptible of lasting injury that their proprietors can ill afford to take unnecessary risks about smallpox among their employees They may with especial propriety keep a sharp lookout as to servants coming from those Southern states where a smallpox is known to exist and where sanitary boards have but little preventive authority It is almost as important for hotel servants to be well protected by vaccination as for nurses barbers, and railroad employees

NECROLOGY

Deaths Abroad—Professor Crocq of Brussels, in his seventy-fifth year, who has so ably represented Belgium in international gatherings and scientific achievements, founder of the *Presse Méd Belge*, president of the Federation Méd Belge, appointed professor in 1855, author of numerous articles "Lead Acetate in Pneumonia," "Study of the Penetration of Solid Particles Through the Tissues," "Application of Auscultation and Percussion to the Horse," "Treatment of Tuberculosis," etc——F Malanco, Mexico, a prominent physician, founder of the *Medicina Cientifica*, and a frequent contributor to other Mexican exchanges

Herman S Beahan, M D, Rochester, N Y, October 2——F P Bibby, M D, Coffeeville, Miss, September 27——J F Boyce, M D, Santa Rosa, Cal, September 30——John Burnett M D, Scranton, Pa, September 30——J B Curtis, M D, Somerville, Mass, October 2, aged 31 years——Hubert D Ensign, M D, Boone, Iowa, October 2, aged 55 years——J C Herrick, M D, Denver, Colo, September 30, aged 54 years——W F McLean, M D, Elyria Ohio, October 5, aged 65 years——S B H Nichols, M D, Corning, N Y, September 30, aged 63 years——James L Ord, M D, Washington, D C, October 3, aged 75 years——D L Paine, M D, Oregon City, Ore, September 30, aged 55 years——R R Ruff, M D, Pitnam, Ark, September 21, aged 67 years——C H Sevier, M D, Brownsville, Tenn September 30, aged 59 years——D W Whittaker, M D, Chattanooga, Tenn, October 3, aged 47 years

MISCELLANY

Personal—Dr Norval H Pierce has resumed his practice, at 31 Washington St, Chicago

Dr Michael Foster, who has just been elected president of the British Association for the Advancement of Science, has been professor of physiology at Cambridge since 1883 He will assume office next year, at the meeting in Dover Sir William Crookes, occupant of the chair this year, is a chemist, his immediate predecessor, Sir William Evans, is an archeologist, while Lord Lister was president in 1896

Requirements for the Practice of Medicine—We have received from Secretary Egan, advance copy of that portion of the annual report of the Illinois State Board of Health, relating to the legal requirements for the practice of medicine in the different parts of the United States, including the territory of Hawaii Its completeness is creditable to the energetic secretary

Higher Standard for Dentists—The Association of German Dentists passed resolutions at its recent annual meeting at Eisenach, urging the authorities to require higher educational attainments of students of dentistry, and a longer course in the university, raising the standard from the certificate of the first grade in the "gymnasium," as at present, to the diploma of a "gymnasium" or "real gymnasium" (high school)'—*Munich Med Woch*, August 23

Science Reveals Nature's Beauty—In his presidential address before the British Association, Sir William Crookes speaks thus brightly to those who are, with him, engaged in wresting the hidden secrets from nature "Steadily, unflinchingly, we strive to pierce the inmost heart of nature, from what she is to reconstruct what she has been, and to prophesy what she shall yet be ' Veil after veil we have lifted, and her face grows more beautiful, august and wonderful, with every barrier that is withdrawn"

Railway Casualties in 1897—In the year which ended June 30, 1897, 6437 passengers on American railways were killed in accidents, and 36,731 were injured A *New York Times* writer, with an arithmetic bent, has figured that only one out of 2,204,708 of the whole number of passengers carried was killed outright, and only one out of 175,115 injured With the total mileage as a basis, the statician figures that the traveler with average luck escapes injury until his journeyings amount to 4,385,309 miles, and not until his score is 55,211,440 miles is it his turn to get killed Traveling 30 miles a day, 300 days in the year, no one need begin to worry until he is 5,467 years old

Rush Medical College—Upon the first year of its affiliation with the University of Chicago Rush Medical College starts out with a class of over 700 students This is especially gratifying to its friends as it shows that physicians and students throughout the country favor higher medical education and appreciate the rigid requirements that are now being enforced As a result of the demands for ample preliminary education, many men have been shut out of the Freshman class, and the policy of sifting out the poorer men from the other classes has elevated the grade of those already in the college After the examinations at the close of the last term, eighty men were notified that they could not advance to the higher classes unless their scholarship could be brought up during the summer months Many of these have dropped out of the college Thirty have been required to take the work of the previous year over again, and the remainder have been given until the fifteenth of November to try to make up their deficiencies, at which time, unless they can remove the conditions, they, too, will be remanded to the lower classes

Oidomycosis—Besides bacterial infection and infection from the streptothrix, we must now make a place for infection from pathogenic blastomycetes, which has been experimentally and clinically established The best known of this group is the saccharomyces albicans, which usually is content to vegetate on a mucosa, but occasionally invades the entire organism and produces a fatal disease Busse reported a case of chronic pyemia caused by a saccharomyces, which produced similar lesions experimentally Curtis also has reported the case of a myxosarcoma of the thigh, containing a yeast fungus, and such cases are multiplying H Roger contributes an article to the *Presse Méd* of August 24, describing the lesions produced by rabbits inoculated with the oidium The granulations invaded the entire organism, and caused hypertrophy of the kidneys, etc (*vide* JOURNAL, pages 199 and 417)

Primary Tuberculosis of the Kidneys —In Professor Israel's operations on the kidneys 10 per cent have been on account of tuberculosis, and in sixteen out of twenty one it was evidently a primary affection He has found it more frequent in women than in men, and unilateral in chronic cases He removed the entire organ in twenty cases Three died from the immediate results of the operation, five deaths occurred later, after partial or complete recovery In regard to the final results Three of the uncomplicated cases died, but the remaining six were permanently restored to health (observations dating from nine years) None of the cases with complications were cured, although some were benefited to a remarkable extent He advises an early operation in simple primary tuberculosis, or if the bladder is but slightly involved He does not operate in secondary ascending tuberculosis, unless to relieve serious disturbances —*Vienna Klin Woch* , September 15

Neuralgia —A Eulenburg contributes a study of the pathology and therapeutics of neuralgia to the *Berlin Klin Woch* , No 33 He does not consider it a definite disease of the peripheral nerves, but attributes it to morbid conditions in the nerve cells, determined by various primary affections of the peripheral sensory neurons Essential neuralgia is distinguished by the characteristic attacks of pain, with intermissions and spots painful to pressure Excentric, that is, neuralgia affecting the roots and root fibers, is characterized by the brevity of the attacks, lancinating pains, while in topic peripheral algias the pain is generally continuous and there are no especial paroxysms He separates hemicrania from the neuralgias, and also asserts that what is called intercostal neuralgia is due to entirely different processes Many cases of ischias, he states, proceed from acute or subacute localized perineuritis of the ischiadicus, propagated *per continuitatem* by the lumbar muscles or primarily affected nerves He frequently arrests and cures ischias with deep injections of 2 per cent carbolic solution —*Munich Med Woch*

Ano rectal Actinomycosis —This is a rare affection, with only seven cases on record Poncet described another observation recently, illustrating his remarks with color photographs, the first application to pathology of the new photography of colors, which "opens a new field for medical iconography " The bladder was secondarily affected, with numerous calculi, some containing fragments of wheat grains—the patient confessed to having inserted a head of wheat in the urethra The ano rectal lesions might at first glance be mistaken for tuberculous, but their special aspect, their color varying from violet to a yellowish red, punctured with yellow points, the slowness in developing, and the presence of the characteristic yellow grains in the pus, soon differentiate it The prognosis is grave, although life may be prolonged many years If internal treatment with potassium iodid proves ineffectual, ablation of the masses and incision of pus pockets are indicated Extensive interventions are justified, as repair progresses rapidly in the tissues which appear to be so profoundly affected, although intervention rarely proves more than palliative —*Bull de l'Acad de Méd* , September 13

The English Tourist Dr Henry S Lunn —Dr Henry S Lunn, the English physician who is well known in England and America for developing the personally conducted touring system, is this year entering upon a decidedly novel plan He has decided to send a couple of sporting and scientific expeditions into the wild regions of Somaliland The cost of these expeditions will be about $3000 for each member, but this includes all expenses for three months a retinue of fifteen servants, twenty camels and two riding horses each, beside the tents and equipments Personally, Dr Lunn is most genial He has had a rather varied career In 1887 he left England for the Indian mission field as a medical missionary As correspondent to the *Pall Mall Gazette*, he attended the Indian National Congress, becoming intimately acquainted with the leaders of the movement, and lecturing to large assemblies of educated Hindus on the development of their national life The vigor with which he threw himself into his Indian work was responsible for a series of attacks of malarial fever, and he was ordered home only twelve months after he had entered the work Dr Lunn is not yet 40 years of age

A Lesson to the Unwary —Medical men in England are dissatisfied at the outcome of a libel suit brought by Dr Morgan Dockrell, physician to St John's Hospital, against the manufacturer of a medicinal water which the doctor had praised and occasionally prescribed The defendant printed and published a circular in which he declared "Dr Dockrell says nothing has done his gout so much good " The jury found that these words were in no wise injurious to the plaintiff's reputation, and hence the High Court of Justice refused to restrain the further publication of the advertisement Dr Dockrell's contention was that the circular conveyed the idea that he was a party to the advertisement, which would be a violation of professional etiquette on his part, and would have rendered him liable to expulsion from the medical societies to which he belonged The jury, however, refused to take this view, and evidently deemed the language justified by what the plaintiff had actually said in commendation of the mineral water in question —*N Y Sun*

School of Medicine for Women New science laboratories in connection with the London School of Medicine, have been opened The school was established nearly a quarter of a century ago, and during this time the work has been carried on in three houses, under most inadequate conditions The leases of these buildings having expired, the site has been obtained and cleared for the new building, which will be erected in three separate stages and is to consist of three blocks The first block, which has already been completed, contains the new laboratories The cost has been between £9000 and £10,000 There are adequate rooms for the teaching of chemistry, physiology, anatomy and physics At present women are enabled to obtain a degree or diploma from nine of the medical examining bodies of the United Kingdom, six of them being universities Since the school started, the students have obtained several gold medals at the London University and at the Royal University of Ireland At the present time the students number 170 Of those who have passed out of the school with a medical qualification some are engaged in responsible work as medical practitioners, some at the new hospital, others in workhouse infirmaries, in asylums, and in various provincial hospitals Others are in India, South Africa, China and Australia

A Defense of Chief Surgeon Girard —The many fierce, not to say brutal, attacks on Lt Col and Chief Surgeon Girard, who is well known to be one of the ablest and most painstaking officers in the army, has led many of his colleagues to write him their personal views of his services We are permitted to extract the following from one of the pleasant tributes thus presented It is from a volunteer surgeon, now mustered out

EXTRACTS FROM LETTER

'I desire to state that I have at all times enthusiastically approved your plan of Division Hospitals, and I am sure that the public mind seems to be gradually coming to its senses in this regard

'It is a probable and an [illegible] ance that t *great mass of the American people will perhaps never fully* realize the almost insurmountable difficulties met and overcome in organizing, harmonizing and equipping the medical corps of the *various regiments of your* command, and the endeavor to elevate their efficiency to something like the standard of the regular army As you know, many of these regiments were absolutely without arms or *equipment of any* kind, when they reached Camp Alger, and it has been truthfully said that 'in some cases there was scarcely cover for the nakedness of the men '

"It became necessary to immediately arrange for the care of the sick This was especially noticeable in the case of the But to return to the subject With a medical corps scarcely organized, some officers even without commission, with no hospital privates, other regiments but partially organized, none thoroughly equipped, and even if fairly well organized and equipped, the military requisites of subordination and discipline were lacking The spirit of opposition characterized by delay and general indifference manifested by some of the volunteer medical officers, as well as regimental commanders, is still fresh in my mind

"The rapidity and completeness in overcoming these obstacles *certainly points to the credit of your command,* and your many years of military training and business tact are the prime factors in its success

"It is true that some medical officers did at times complain of trivial delays and possible lack of equipment, but as a rule the basis of these complaints was groundless There never was a time when their requests were not promptly honored, if reasonable, and supplies promptly granted when circumstances permitted These complaints as a rule were voiced simply for effect, as a general disapproval of what certain volunteer officials considered an interference on part of the regular army officials with the rights of the volunteer

"That such harmonizing was necessary is evident, that it was accomplished is apparent in the present efficient management of these departments Having overcome all these difficulties with complete satisfaction to all, is certainly a glowing tribute *to your faithful* and *untiring efforts to excel* in the efficiency of your medical corps All these conditions I describe fully in my sanitary report which I am now preparing *for* the Surgeon General

"In conversation with a number of my friends shortly after I arrived at Camp Alger, I was frequently asked 'how I liked Chief Surgeon Girard?' It was the general opinion among them that you were the right man in the right place They said 'Girard is considered the best disciplinarian in the Medical Department of the U S Army ' To some this perhaps seemed a fault, but I consider it to be the highest compliment, and I congratulate myself upon being so fortunate as to have been under your medical direction, as I am fully aware that without discipline organization can not be maintained nor progress assured "

Hospitals

The new St Joseph's Infirmary, Fort Worth, Texas, was formally opened September 29 It is a fireproof, three story structure of brick, 170 by 150 feet ——The new hospital for the special treatment of tuberculosis at Dunning, Ill , was dedicated October 8 The cost of the building, three stories in height, was $54,200, with furnishings $64,200

Societies

The following recent meetings are noted

Illinois —Chicago Medical Society, October 5, Chicago Pathological Society, October 10, Will County Medical Society, Peoria, October 11

Indiana —Upper Maumee Valley Medical Association, Fort Wayne, October 6

Iowa —Cedar Valley Medical Association, Waterloo, October 11, Clinton County Medical Society, Clinton, October 4, Polk County Medical Society, Des Moines, October 4

Missouri —Jasper County Medical Society, Joplin, October 4, Medical Society of the City Hospital Alumni, St Louis, October 6

New York —Broome County Medical Society, Binghamton, October 4, Onondaga Medical Society, Syracuse, October 4, Orange County Medical Society, Newburgh, October 4

Ohio —Marion County Medical Society, Marion, October 4, North Central Ohio Medical Society, Marion, September 30

Pennsylvania —Lackawanna Medical Society, Scranton September 30

Vermont —State Medical Society, Brattleboro, October 13 and 15

Cincinnati

Hospital Internes —On October 10 the terms of service of four of the internes of the Cincinnati Hospital will expire, they are Drs H J Ware, Edward Francis, William Muhlberg and Percy Shields Drs H H Hines, C F Beeson and A H Smith will take their places Dr T S Morrison, the other successful candidate, is at present in Manila, assistant surgeon of the First Regiment, Wyoming Volunteer Infantry, a part of General Merritt's immediate command

Academy of Medicine —At the regular meeting, October 3, Dr C A L Reed read a very interesting paper on "Fat and Fecundity "

Dr Charles H Castle, surgeon First Ohio Cavalry, is in the city, waiting for the muster out

Dr S P Kramer writes from Camp Wikoff as follows "The *typhoids are very typic, but in many cases they are* associated with malaria One sees cases that are clinically undoubtedly typhoid, and in addition the plasmodium of malaria is found in the blood " In speaking of malaria he says "The malarial cases are not typic at all Very few are purely intermittent, *most of them are remittent,* and *many of a* pernicious nature In the latter cases the best results are obtained from the hypodermic administration of the double chlorid of quinin and urea " The dysentery prevailing, the doctor thinks, is largely due to malarial poisoning The yellow fever cases, he says, are few, and there is little or no danger of the infection spreading

Philadelphia

Pamphlet on Yellow Fever —As yellow fever prevails in several sections of the South, with the probability of its spreading still further, the State Board of Health has been energetic in educating the laity regarding the nature of, the disease and it proper prevention Looking to this end a pamphlet has been printed and is being *freely distributed throughout* the State, giving all of these necessary details and pointing out that the baneful effects are not so severe as is generally supposed

Dr Pepper's Successor Still Sub Judice —At a recent *meeting of the trustees of the University of Pennsylvania,* the subject of Dr Pepper's successor was again presented for discussion, but owing to the action taken at a previous meeting, distributing the work among four of the faculty, no definite action was taken Didactic lectures will be given by Drs Stenger, Musser, Packard and Fussell, while Dr James Tyson will have full supervision over both this department and the clinical lectures until the trustees take some definite action in the disposition of the chair The four years' course of eight months each demanded by this institution, has not kept down the number of matriculates, but, in fact just the reverse has occurred It is a matter of serious reflection why so many men go into the medical profession, whether it is due to the hard *times which impels them to choose something,* or whether it is from other causes

Public Schools and Diphtheria —From the fact that diphtheria has been so prominent in several of the public schools of the city, the Bureau of Health is using every effort to prevent the disease from spreading To this end, therefore, it is that suggested to keep down these local outbreaks that the *schools be thoroughly disinfected daily in the following* manner "The daily sprinkling of the floors before sweeping with a disinfectant solution, the use of individual drinking cups and the disinfection of pencils The attention of the Bureau of Public Education has been called to most of these unsatisfactory conditions, but it is doubtful if any special attention has been given to the matter It is work that can and should be done by the Board of Education The desk tops should be wiped off daily with a disinfectant solution and the hand rails should be treated in the same way *It would not be safe to* use a solution of bichlorid nor even carbolic acid " It is suggested that these suggestions be given to the janitor in order that they be carried out A paper was received and referred to the Board, asking that disinfectants also be put in the street sprinkling wagons in order to destroy the germs which make their habitat in the dust of the public thoroughfares

Dr Pepper Esteemed —It is stated that members of the International Advisory Board of the Philadelphia Commercial Museum very frequently receive letters of condolence from friends of Dr Pepper in all parts of the world These letters not only show that he was known as a physician of distinguished ability, but as a public spirited citizen In Mexico, where he presided over the deliberations of the Pan American Medical Congress, marked honor has been shown Delegates to the meeting held at the Philadelphia Commercial Museum also pay high tribute to his memory The Mercantile Confederation of the Republic of Mexico, at a recent memorial meeting, President Diaz being present, and at which time the national flag of that republic, with that of the United States, were entwined about the hall with a tinge of crape, gave a heartfelt feeling to the words spoken in honor of the name of William Pepper

Pay for Soldiers —The government has recently inquired of the hospitals of this city as to the amount required by each of them for the care and treatment of the sick soldiers brought here So far no definite arrangement has been made toward asking the government to defray the expenses for this trouble, and it seems the action of the government has been voluntary It is reported that those soldier patients now in the New York hospitals each receive pay at the rate of 93 cents a day The treasurer of the National Relief Association ackowledged receipts of money and supplies aggregating the sum of $107,511 48

Tuberculosis still Decreasing —In the annual report of the Pennsylvania Society for the Prevention of Tuberculosis, facts are tabulated showing a gradual decrease in the number of deaths from this disease In Philadelphia statistics are presented proving these claims In 1870 there were 2308 deaths, or 3 42 per 1000 of the population, in 1880 the percentage was 3 17, in 1890, 2.64, and in 1897, with 2385 deaths, the percent-was 1 96 A site at White Haven, Luzerne County, has been offered to the society for a sanitarium, and it is hoped that proper aid will be given by the State for the erection of a building suitable for the care of those suffering from consumption

Bequest of $400,000 —Through the death of Joseph M Bennett of Philadelphia the University of Pennsylvania will receive property to the value of $400,000 The provision making the bequest is as follows "I will and bequeath to the trustees of the University of Pennsylvania the property, 1021 Chestnut Street, adjoining the Chestnut Street Opera House, also the properties 3340, 3342, 3344 and 3346 Walnut Street, being east of the properties which I have heretofore donated at the corner of Thirty fourth and Walnut Streets, known as Bennett Hall to said trustees Now, my object in making this bequest is to further aid and encourage the said trustees in carrying out more practically and thoroughly the co education of women and girls in relation to the scheme which has been commenced in the said houses," etc

Mortality Statistics —For the week just closed the records of the Bureau of Public Health show that there have been 408 deaths, 137 being children under 5 years of age The following are the principal causes Alcoholism 2, apoplexy 17, nephritis 20 cholera infantum 8, cholera morbus 1, tuberculosis 42, membranous croup 4, diabetes 1, diarrhea 2 diphtheria 22, heart disease 27, typhoid fever 14, dysentery 4, homicide 1, marasmus 31, septicemia 3, suicide 1, tetanus 1 uremia 7, whooping cough 2

Hospital Train Sent Out —Jefferson Medical College recently dispatched a hospital train to Camp Meade, returning with fifty two patients It is stated that most of the patients were in a very serious condition The train was in charge of Dr H A Hare, assisted by Drs M H Williams, E H Wiggins, J L Scallinger and Hiram R Loux A corps of twelve nurses accompanied the train

Camp Meade —Dr Shakespeare, a member of the board appointed by the War Department to investigate the prevalence of typhoid fever among the different army camps, has been detailed to make report regarding the conditions existing at Camp Meade It is stated that in this camp the disease is mostly confined to the troops belonging to the Two Hundred and Second and the Two Hundred and Third Regiments of New York

The Jefferson and Medico Chirurgical Medical Colleges —During the week just passed both of these institutions began their sessions for the coming year At the Medico Chirurgical, exercises were also held in the dental and pharmaceutic departments, both of which have been recently established

Salaries of Prison Inspectors —A recent decision of Judge Pennypacker of Philedelphia, handed down in a contested case, states that the Board of Prison Inspectors of the county prison and not the city councils have the right to fix the salaries of officers of the county prison

Washington

Health of the District —The report of Health Officer Woodward, for the week ended October 1, shows the total number of deaths to have been 106—48 white and 58 colored The principal causes of death were Nervous diseases, 13 genito urinary, 7, circulatory, 4, intestinal, 10, typhoid fever, 4, diphtheria, 7, measles and whooping cough, 1 each At the close of last week there were 79 cases of diphtheria under treatment, and 44 new cases reported during the present week, 19 were reported cured, leaving 104 cases under treatment at the close of the present week There were 68 cases of scarlet fever under treatment at the close of the week Dr Woodward says there are a large number of cases of diphtheria in the district One year ago the number was 44, while this year, on the corresponding date, there are 108 cases, an increase of more than 200 per cent The cases existing at present are distributed among 79 places, while those of a year ago were located in 36 places He says the large increase in the number of cases is accounted for by the improvement in diagnosis Cases which formerly were called sore throat or tonsillitis or croup, are now known to be diphtheria, and after bacteriologic test, are reported as diphtheria The increase in the number of cases is of course accompanied by an increased death rate The disease is more prevalent among the poorer classes, and ignorance and carelessness on the part of these people is largely responsible for the increase of the disease I know of five cases where children were ill before a physician was summoned, one of whom being so ill that it died the day the doctor was called The opening of the schools is usually another cause for the increase of the disease, due probably to the massing of a large number of children We are doing all we possibly can to check the spread of the disease, but we are greatly hampered by the limited authority of the Health Department

Army Investigation —Surgeon General Sternberg, in reply to the questions relating to the Medical Department management, forwarded to him by the Investigating Commission, replied as follows

To President of Board to Investigate the War Department

Sir —I have the honor to submit for the Committee of Investigation, the enclosed statement relating to responsibility in the Medical Department of the Army I respectfully suggest that the commission as a whole or a sub committee, visit the office of the Surgeon General at an early day for the purpose of investigating the organization and methods of work which have been employed in my office during the war with Spain I have received a copy of the questions relating to the Medical

Department, and shall do my best to answer these questions in full at as early a date as is practicable, but considerable time will be required, owing to the enormous amount of important official business, pertaining to the regular administrative work of the office To neglect this would give just cause for criticism, and I am sure that the commission will agree with me, that my first duty is to provide for the proper care of the sick of our army, in the field and in garrison, so far as this lies in my power This has been my earnest endeavor from the outset of our short and glorious war with Spain Very respectfully,

GEORGE M STERNBERG, Surgeon General U S Army

MEDICAL ASSOCIATION —The regular stated meeting of the association of the district was held on the 4th instant The Standing Committee, who had been entrusted with the enforcement of the regulations governing medical charities in the district, reported that all the hospitals were carrying out these rules and regulations, both in letter and spirit The following were elected to active membership Drs Chas E Furgeson, Bernard L Hardin, Frederick M Hartsock, Harry Hurtt, L Fleet Luckette, C H Mechineck, W P Malone, Wm Gerry Morgan, John B Mullins, Wallace Neff, Edward D Perkins, T Lyman Perkins, John J Repetti and Stanley S Warren

DISTRICT MEDICAL SOCIETY —At the meeting of the medical society, October 5th, the following were elected to membership *Drs Isabell Haslup, Maurice E Miller, Jessie Ramsburgh*, John C Simpson and Victor E Watkins Dr James Kerr read a paper entitled, "Treatment of Colles' Fracture by Gordon's Splint" *He presented the splint of Dr Gordon* of Belfast, explaining its special advantages based upon the skiagraphic study of this fracture, and showed the disadvantages of *the other methods of treatment He said the use of* the Gordon splint had given universally good results in his cases An interesting discussion followed, pro and con, participated *in by Drs Hammond, Van Rensselaer, Hough* and Frederick In closing, among other things, Dr Kerr said facetiously, that the bad results reported by the speakers *occurred in the cases* where the Gordon splint had not been used The president, Dr Busey, announced the death of Dr Draughbaugh in the army at Santiago, and upon motion a committee was appointed to draft suitable resolutions to be sent to the family of the deceased

DR GALLINGER —Dr Ralph E Gallinger, son of Senator Gallinger, has resigned from the assistant staff of the Central Dispensary and Emergency Hospital, and has begun practice in Concord, N H

DEATH OF DR BREWER —Dr Madison M Brewer, one of the surgeons who recently returned ill from Santiago, died of typhoid fever at Garfield Hospital on the 3rd inst Dr Brewer was son of Dr John Brewer, U S A, was a graduate of the Columbian Medical College, and formerly resident physician at the Garfield Hospital

CHANGES AT THE EMERGENCY HOSPITAL —The term of service of Dr James D Fife expired on the 30th ultimo, and Dr W N Glover was appointed resident physician to succeed him Dr W H Mohart became first assistant, and Dr Thompson, of the University of Virginia, who recently passed the competitive examination, was appointed second assistant resident

REPORT OF COMMISSIONERS OF PHARMACY —Dr John T Winter, president of the Commissioners of Pharmacy, has submitted their annual report for the year ended June 30 The report shows that thirty applicants were examined during the year Eight of the applicants passed satisfactory examinations and were licensed, twenty two failed to pass after a second examination, and were refused registration, thirty seven graduates of chartered colleges of pharmacy were registered on the presentation of their diplomas

GEORGETOWN MEDICAL SCHOOL —The Medical Department of the Georgetown University began its session on the 2d, with a large increase in the number of its students The University Hospital is doing *excellent work* The Emergency Department is in charge of Dr W C Gwynne as resident, and Dr James J Kilran as extern Dr J J Kinyon was appointed Professor of Pathology and Bacteriology, D J D Morgan, Professor of Clinical Medicine and *Dr C L Allen*, Clinical Professor of Diseases of the Nervous System Dr J W H Lovejoy resigned the chair of Theory and Practice of Medicine, and was elected Emeritus Professor of Theory and Practice of Medicine Dr Samuel S Adams has been elected his successor Dr Lovejoy was one of the original faculty at the opening of the school in 1851, holding the chair of Professor of Chemistry until 1854 In 1880, after an interval of twenty six years, Dr Lovejoy re entered the faculty as Professor of Materia Medica and Therapeutics which he continued until 1883, when he was elected to the chair of Theory and Practice of Medicine, on the resignation of Dr Samuel C Busey

MEDICAL DEPARTMENT COLUMBIAN UNIVERSITY —The Medical and Dental Departments of the Columbian University opened their respective schools on the 3d instant Dr W W Johnston, Professor of Theory and Practice of Medicine delivered the address to the medical students, and Dr J Hall Lewis, Dean of the Dental Faculty, addressed the dentals Dr E A DeSchweinetz, Dean of the Medical School, announced the formal opening of the Columbian University Hospital

ADDRESSES

THE RISE, PROGRESS AND PRESENT NEEDS OF PEDIATRICS

Address of the Chairman of the Section on Diseases of Children at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10 1898

BY J P CROZER GRIFFTH, M D

CLINICAL PROFESSOR OF DISEASES OF CHILDREN IN THE UNIVERSITY OF PENNSYLVANIA

PHILADELPHIA PA

The honor which you have done me in electing me your chairman brings with it the duty of opening the session with an address I have chosen as my subject one of great importance to us, one in which I have felt great interest and to which I have given considerable thought during a number of years, and I dwell on it now hoping to awaken in you, if need be, an equal interest in the matter, and that together we may aid in advancing the position of the branch of medical science which we represent today The subject to which I refer treats of the rise of pediatrics as a specialty, its present position as compared with its past and its needs for future growth I can give you but an incomplete sketch, lacking in very many of the most important details

One is often surprised that our medical forefathers knew so much One is also surprised that they knew so little, and yet were undoubtedly useful members of society They had the distinct advantage over us that each man, if well trained, knew all of everything medical that there was to be known This was because there was not so much to know The enormous additions to medical knowledge which went on as years passed rendered the arising of specialties in medicine an absolute necessity, yet it appears strange that pediatrics should seem to have developed so slowly as a special department That no special teaching of it was given in any medical schools was probably due to the grave mistake of viewing the child only as a little man, of imagining that the teaching of the " Principles and Practice of Medicine ' gave ample preparation for the encountering and mastering of the infant's disorders, and later of making the curious assumption that because a physician understood the diseases of women he must therefore necessarily have special cognizance of diseases of children—a view still prevalent in some quarters but waning rapidly

But as a matter of fact the recognition of diseases of children as a specialty was developing long before the fact was appreciated The branch has existed always Every practitioner of every age had to learn it to some extent, although unfortunately this was accomplished often only at the expense of the lives of his little patients The urgent demand for post-graduate instruction less costly of life than this was followed naturally by the production of special text-books, by the development of journal literature on pediatric subjects, and finally, and much later, by the establishment of special hospitals for children, of special medical societies to study their diseases, and of special instruction given to undergraduates—a much better plan than that of trusting to that expensive teacher, Experience

Let us look briefly at the development of pediatrics in these different respects

Text-books —Many matters in the domain of diseases of children are treated of in the works of the ancients, but the first book devoted solely to the subject, as far as I can learn, was written by Demetrius of Apamia about 260 B C, and was entitled "De morbis puerorum " Then in the Middle Ages we find a work by El Rhazi, about the end of the ninth century, A D, called "De ægritudinibus puerorum " In 1472 appeared the work of P Bagellardus of Fiume, "De ægritudinibus et remediis infantum," and in 1473 Metlinger's book " Ein vast nutzlich Regiment der junger Kinder," which, according to Hennig, was the first printed book upon the diseases of children The first book about children written in England was by Th Payn, 1569, entitled "The Regiment of Life, whereunto is added a Book of Children " In 1653 Pemel wrote " De morbis puerorum," and some time before 1639 Harris published ' De morbis acutis infantum " Sydenham, in a letter to Harris said "Without flattery, you are the first man I ever envied and it is my belief that your little book will be more useful to mankind than all I have written "

Very many books in this department of medical science have appeared in Europe since these times, and, as years passed, the rate of appearance constantly increased In recent years, from the classic "*Handbuch*," edited by Gerhardt, down to the valuable "*Traité*," edited by Grancher and his associates, and just completed, the large number of books on pediatrics of all sizes and range which have been issued bears ample testimony to the great interest in the subject taken by writers and readers abroad

The development of text-book literature on diseases of children in the United States is even more interesting to us This matter was so exhaustively reviewed by Adams that I shall touch it only briefly, and refer you to his valuable paper for fuller details The first pediatric monograph appears to have been by Charles Caldwell written in 1796, and entitled "An Attempt to Establish the Original Sameness of Three Phenomena of Fever (principally confined to infants and children) described by Medical Writers under the Several Names of Hydrocephalus Internus, Cynanche Trachealis and Diarrhea Infantum " The first book especially devoted to children was published in 1790 This was written by a layman (or rather a lay-woman) and was called ' The Maternal Physician " The first book on pediatrics by a physician was entitled "Practical [illegible] on Diseases of Children, etc ," and was written by George Logan in 1825 In the same year the celebrated Dr Wm P Dewees, so well known as one of the earlier eminent American physicians, published his work on children's diseases From this date onward the American books upon pediatrics have been rapidly multiplying Among them may be mentioned the works of Condie, Eberle, Meigs, Lewis Smith, Jacobi, Rotch and Holt, not forgetting the "Cyclopædia of the Diseases of Children," edited by Keating the only work of the sort in the English language, and one of which we can justly be proud

Pediatric Journals —With regard to medical journals devoted to diseases of children, the first of which I can learn was one denominated *Archiv für die Geburtshilfe, Frauenzimmer und-neugeborner Kinderkrankheiten* This was issued in 1787 The first journal devoted exclusively to diseases of children appears to have been *Analekten über Kinderkrankheiten*, which was commenced in 1834 Neither of these journals is longer current Since this time there have been numerous journals started, some of them still existing I count at present four in German, the oldest being the well known *Jahrbuch für Kinderheilkunde*, begun in 1857 The other three are, in order, the *Archiv f Kinderheilkunde*, the *Kinderarzt*, and the *Centralblatt f Kinderheilkunde* There are four in French, of which the oldest is the *Revue mensuelle des Maladies de l'Enfance*, started in 1883, and the others, in order, the *Journal de Clinique et de Therapeutique Infantile*, the *Annales de Médecine et Chirurgie Infantiles*, and the *Archives de Médecine des Enfants* There are one in Italian, *La Pediatria*, two in Spanish, the *Anales de Obstetricia, Ginecopatia y Pediatria*, and the *Archivos de Ginecologia y Pediatria*, and one in Russian, the *Dietskaya Meditsina* All but the two Spanish journals are devoted exclusively to diseases of children Curiously, of journals published in English, there is not one owned and edited in England

The United States is well represented in journals treating in part or entirely of the diseases of children The *American Journal of Obstetrics and Diseases of Women and Children* was first issued in 1868 From the beginning it included articles upon the diseases of children, and later it set aside special pages for this department The *Archives of Pediatrics* was established in 1884, the *Annals of Gynæcology and Pediatry* in 1890, and *Pediatrics* in 1895.

It it evident, then, that journals treating specially of diseases of children, slow to start, show at present no dearth Certainly this indicates the rapid strides which the interest in the subject has made nearly everywhere in the medical world

Children's Hospitals —Regarding hospitals for sick children, I find that the first of any sort appears to have been the Dispensary for Sick Children, founded in London by G Armstrong, in 1769 It became extinct on Dr Armstrong's death It was intended only for out-patients, as was the one founded by Mastalier in Vienna in 1787 In 1802 the Maison de l'Enfant Jesus in Paris was changed, on the suggestion of Tenon, from an orphan asylum into a hospital for children of from two to fifteen years of age This hospital, still in existence as the Hôpital des Enfants Malades, was the first institution designed solely for the care of sick children within its walls It was not until thirty-two years later, in 1834, that the second hospital was founded—the Nicolas Children's Hospital in St Petersburg The development since then of similar institutions in different localities advanced at first only slowly, then moved rapidly In 1852 the Great Ormond Street Hospital was founded in London At that time, writes Dr Charles West, there was no other hospital in England or America for diseases of children

What a wonderful change since these early beginnings! Hospitals for sick children are scattered all through England, London alone having quite a number, and the cities of Continental Europe are thoroughly well supplied

The first hospital to be started in the United States would appear to be the Nursery and Child's Hospital in New York, founded in 1854 and still in existence Yet this institution was at first a maternity as well, and the oldest hospital purely for children is undoubtedly the Children's Hospital in Philadelphia, which was established in 1855 Now a glance at the list of benevolent institutions in the United States fills one with astonishment at the number of general and special hospitals for children, the homes, asylums, sanitoria, etc , throughout the country, to say nothing of the children's wards connected with nearly all the general hospitals for adults

Pediatric Societies —Next let us consider the subject of medical societies for the study of diseases of children All advance in this line has been very recent, leaving still much to be desired Although England has numerous other special societies, such as a Balneological Society, a Medical Temperance Association, two Dermatological Societies, a Society of Anesthetists, etc , I have not yet been able to learn of a single organization devoted solely to pediatrics, out of 79 Provincial medical societies and 71 in London itself! The British Medical Association generally has a pediatric section, but not always, as for instance, at its meeting in 1897 There is not in Germany or Austria, as I am informed authoritatively by correspondents, a single independent society devoted to the study of diseases of children The same has been true of France until within a few months I have read very recently in the *Journal de Clinique et de Therapeutique Infantile*, that the hospital physicians of Paris are about to start a society of Infantile Medicine and Surgery In Russia there appear to be two, one in St Petersburg, started, as nearly as I can learn, in 1885, and one in Moscow, started, I believe, in 1892 Each publishes volumes of transactions Of pediatric societies in other European countries I can not speak authoritatively, but I have heard of none The Gesellschaft der Naturforscher und Aerzte has its pediatric section established in 1883 and meeting annually The International Medical Congress has likewise a pediatric section There was started in France in 1897 a Congress of Gynecology, Obstetrics and Pediatry, which is to meet annually In Berlin, Dr Baginski holds every two weeks, for the discussion of pediatric subjects, an informal gathering of men who have been his assistants

This paucity of societies for the study of children's diseases in Europe, is in contrast with the manifestation of interest in this direction which the United States has shown, particularly recently The American Medical Association established the Pediatric Section, whose session we are now attending, in 1880, with Dr A Jacobi as its first chairman The amount of work done is instanced by the overcrowded program before us for our present meeting There are, as you notice, sixty-two papers announced, and we were obliged to refuse quite a number of applications on account of lack of time to have the papers read When we consider that the ASSOCIATION is meeting this year over two thousand miles from the more densely populated Eastern States, the activity and interest in pediatric studies which the program shows is really astonishing

In 1860 an attempt was made by the New York Academy of Medicine to form a Section for Diseases of Children, but after a few meetings it was abandoned Years later, in 1887, the present Pediatric Section was started, with Dr J Lewis Smith as its first chairman This organization contains many of the leading writers on children's diseases in the country It has always been a very active one and has issued a large amount of valuable matter

The American Pediatric Society was established in 1888, with Dr A Jacobi as its first president It has from its origin been an exceedingly active organization Its volumes of Transactions contain a large amount of valuable scientific work and are appreciated at home and abroad

The Pan-American Medical Congress was founded in 1893, with a pediatric among its other sections, and Dr John M Keating as the first chairman of this section

This covers the national pediatric associations Recently there have been established some State societies The Ohio State Pediatric Society, meeting once a year, held its first meeting in May, 1895, with Dr S L McCurdy as its first president, and the Indiana State Pediatric Society, likewise meeting yearly, was organized in December, 1897, with Dr P J Barcus as its first president, and holds its first meeting this year I know of no other State societies up to the present time

Of independent city societies for the study of children's diseases, there is in St Louis the Bethesda Pediatric Society, which was organized in the autumn of 1895 with Dr E W Saunders as its first president Its membership is limited to fifteen, but invitations to outsiders are extended for each monthly meeting The interest is great and the meetings enthusiastic

The Philadelphia Pediatric Society was established December 1896, and holds its meetings monthly It has proved a success beyond all expectation, has a large membership and interesting and well attended meetings at which much work is done Its proceedings are published regularly in several medical journals I feel greatly honored in having been its first president and in having had the opportunity to review the work of the first year in an address published in the *Archives of Pediatrics* a short time ago It is possible, and even likely, that there are other city societies of which I have been unable to learn Certainly they are to be welcomed

Public Teaching of Diseases of Children —Finally let us consider the status of the public teaching of pediatrics in medical schools An interesting and valuable contribution has been published on this subject by S W Kelley, which approaches the matter from another point of view, and therefore duplicates little, if at all, what I shall have to say

Dr Jacobi is my authority for the statement that Rosenstein, who wrote a text-book on diseases of children in 1752, and his predecessor, Roberg, introduced clinical instruction in diseases of children in Stockholm This would appear to be the earliest instance of the official special teaching of the subject As far as I can learn there was no other public teaching in Europe until about 1850, when Giraldès gave instruction in surgical and Bouchut in medical affections of children in Paris, while at about the same time Mauthner was teaching pediatrics in Vienna, and Hauner in Munich About 1858 Ehlers began lecturing in Berlin The branch now receives attention in nearly all of both the large and the small universities, and is represented in many of them not by a clinical chair but by a recognized full professorship In this respect Europe is still decidedly ahead of us although we are rapidly gaining

In England, however, the teaching of pediatrics would seem for the most part to be far from satisfactory According to a recent editorial appearing in *Pediatrics*, taking St Thomas' and St Bartholomew's as examples of what prevails in most of the London hospital schools, there are no special lectures on pediatrics given at all In Manchester, under the teaching of Dr Ashby, conditions appear somewhat more advanced In Edinburgh a lectureship on this subject has been established only within very recent years

How is it regarding the public teaching of pediatrics in the United States? Although Gunning Bedford, about 1850, taught diseases of children in a mixed women's and children's clinic in the University Medical College of New York, the first special chair in this department was established in the New York Medical College in 1860 and given to our distinguished fellow-physician, Dr Jacobi Since that time what a change! Yet the change came but slowly Dr Jacobi, writing in the Cyclopedia of the Diseases of Children in 1888—only ten years ago—says "To my knowledge there is no school in the country which lays the least stress on that branch of instruction No examination being required by those to whom the student looks for direction and enlightenment, he neglects the study, to find out too late the mistake he has made in doing so"

Now, as I said, what a change! How the profession throughout the country is awakening to the demands of the times! No need to ask longer whether pediatrics is or should be a specialty See only what the colleges are doing, for the proof that its position is being fully recognized In order to illustrate this point I have examined and compared lists of regular medical colleges in the United States and, with the assistance of our secretary, Dr Rosenthal, have applied to all of them for recent announcements and reports From the great majority these have been received, but for the information regarding a few I have been obliged to depend upon the schools' advertised list of teachers I find the names of 130 colleges, from which must be excluded 13 of which nothing whatever could be learned (The post-graduate schools are not included in the analysis, although all of them have full chairs of diseases of children) A study of the 117 remaining schools is most interesting In 64 of them, i e, 54 7 per cent, there is a special chair for pediatrics In 43, i e, 36 75 per cent, the chair is combined with some other department—not by any means always as the minor subject and never buried in it without mention of the title In 3 colleges there is only a lectureship In only 7, i e, 5 98 per cent, is there no announced teaching of diseases of children, and I have knowledge that in some of these 7 special instruction in pediatrics is given In all but 7, then, out of 117, the published announcements recognize the importance of pediatrics and advertise the teaching of it

Further, of the 64 colleges in which the department has its own independent chair, in 49, i e, 76 55 per cent, the title is that of "Professor of Pediatrics" or "Professor of Diseases of Children" In only 15, i e, 23 43 per cent, the title is a minor one, usually "Clinical Professor," sometimes "Associate Professor," and in one instance "Professor of Clinical Pediatrics"

No positive conclusions can be drawn from these facts, but from them, with a study of the catalogues, certain very suggestive inferences are justifiable It was clear in most cases where the title of "Professor" is given that the teacher is a full member of the faculty, and his department admitted as equal to any other This shows well the recognition which pediatrics has gained throughout the country Even in cases where this inference could not be drawn, another was evident, viz, that the Professor is not limited to clinical work alone, but has, if he wishes it, the option of giving a systematic course in his department In fact, this is distinctly stated in many cases In the smaller number of colleges where such a title as "Clinical Professor" is employed I know that in some instances at least the teacher has this option I dwell upon this point because my belief is that pediatrics should be taught both clinically and didactically, and I think the figures I give prove that this is now the commonly accepted opinion throughout the country

As to the numbers of hours given to pediatrics I can make no positive generalizations As far as it could be determined the number of hours varies greatly in different schools, and is often much below what it should be

Some more accurate details may be of interest About two years ago, with a special purpose in view, I addressed a series of questions to the holders of chairs of diseases of children in a number of the leading medical schools of the United States, selecting chiefly those in which an independent chair existed, and a number of others in which the department was combined with some other, but where active teaching in pediatrics was going on The questions were personal to a certain extent, and I feel authorized therefore in giving only the results in general, without mentioning the names of the institutions

I have accurate statistics of 28 colleges, not gleaned from the catalogues, but from the direct answers of the teachers themselves In 17 of the 28 colleges the department of pediatrics is represented upon the governing medical body of the school This does not represent the actual percentage which holds good for all the schools of the country, for it happens that the 28 schools selected had an unusually large proportion of *clinical* chairs In 14 out of 24 colleges suitable for comparison the professor of pediatrics receives a salary This large proportion does not fairly represent the true importance which is attached to the chair by most schools, since in certainly 5, and probably in nearly all of the remaining 10, circumstances compelled all or nearly all of the other chairs to be unremunerated also Therefore, in almost every one of the 28 colleges studied, the teacher in the department of the diseases of children is considered of sufficient importance to receive remuneration for his work In all but 5 of the 28 colleges there are a number of other officers beside the professor who are actively engaged in teaching diseases of children In 23 of the colleges didactic as well as clinical instruction is given, in a large number of the 28 ward class instruction is also used, while in a considerable number recitations are likewise held In at least 19 of the 28 the chair does not depend on dispensary patients alone for clinical material, but has ward patients also

All these facts are proof—if proof were needed—of the high estimation the medical schools have of the importance of pediatric teaching Finally, in all but three of the twenty eight colleges, i e, in 89 per cent, there is a required final examination by the professor of pediatrics In most of them this ranks with all other examinations Here is the evidence that most medical schools are alive to the fact that pediatrics is important enough to *require* their students to study it How different from the condition of ten years ago, as Dr Jacobi shows in the words I have already quoted

We have hastily reviewed the rise of pediatrics as a special branch of medical science, and the astonishingly rapid progress which it has made in very recent years What now are its needs? The little I have to say here can be said briefly

First, there is the need that the recognition of the importance of special teaching in diseases of children to medical students shall become universal Almost all of the newer and more progressive schools do appreciate this I am sorry to say that in some of our oldest and best known institutions, where one should expect the most advancement, the branch receives even yet by no means the recognition which it deserves, and which the schools of Germany and France are giving it Conservatism is good in its place, but when pushed too far it becomes merely "old-fogyism" It may be safely prophesied that not many years will pass before the demands of the times, the demands of undergraduates—for these fully realize the value of pediatrics to them—will force even our most conservative colleges to discard for the new garments of modern progress that shabby, threadbare mantle of antiquity and precedent which they have so long and so closely wrapped about them

Then, in nearly all of our schools there is the need that much more time be allotted to the study of children's diseases and that more clinical material be provided for practical personal study by the students In no other way can the students be given that actual knowledge of children's ailments which they are sure to need very early in their career as physicians Finally, there is a need not to be overlooked—that no attempt shall be made actually to dissociate pediatrics from the main branches This is equally true of all specialties, both in their teaching and their practice The effort so to separate can do only harm and can not possibly succeed Special teaching is absolutely required It is impossible now-a-days for the professor of medicine or the professor of surgery to cover the ground in the time at his disposal But for all specialties there must be the foundation of the main branches of medical science, and all special branches must be studied in their bearing upon these In one sense pediatrics is wider than general medicine It is different from all other special branches in one important particular These latter instance the application of general medical knowledge to special organs of the body Pediatrics, however, is special knowledge of disease as it expresses itself in the general system of the child The general physician need know little of children's diseases The pediatrist must not only know adult medicine but special child medicine as well

What must be our aim, then, as physicians interested in this great branch of medical science? To so study it, practice it, write of it, teach it, work for it, that we may fit ourselves and others to aid in the best way the most helpless and defenceless, the most attractive, the most appealing of our patients—the children

In closing I must express my indebtedness for valuable information obtained from the article by Rauchfuss on "Die Kinderheilanstalten," and that by Hennig on "Die Geschichte der Kinderkrankheiten," both in Gerhart's *Handbuch der Kinderkrankheiten*, Vol 1, that by Jacobi in the Introduction to the Cyclopedia of the Diseases of Children, that by Adams, on the "Evolution of Pediatric Literature in the United States," in the *Archives of Pediatrics*, June, 1897, and that by Kelley on "Pediatrics, Past, Present and Future," in the *Cleveland Medical Gazette*, September, 1896 Meissner's "Grundlage der Literatur der Pädiatrik", an editorial in *Pediatrics*, Jan 15, 1897, the Index Catalogue of the Library of the Surgeon-General's Office, Polk's Medical and Surgical Register of the United States, the Medical Directory for England, and the Bibliographical Supplement of the Cyclopedia of Practical Medicine, by Forbes and his associates, have all been of service I am also much indebted for information furnished in personal letters from Dr Guinon of Paris, editor of the *Revue Mensuelle des Maladies de l'Enfance*, Dr Frühwald of Vienna, editor of the *Archives für Kinderheilkunde* Dr Baginski and Dr Heubner of Berlin, Dr Saunders of St Louis, Dr Lambert of Indianapolis, Dr Rotch of Boston, Dr Adams of Washington, Dr Booker of Baltimore and Drs Brown, Adriance and Carr of New York Last, and especially, I am indebted to Dr Jacobi of New York for many useful suggestions and much valuable information given, both in personal letters and in conversation

---

THE LIMITATIONS OF MEDICINE

Address Delivered at the Opening Exercises of Rush Medical College September 27, 1898

BY FRANK BILLINGS, M D

CHICAGO, ILL

Medicine has for its object the relief of suffering and the prolongation of life There exist many limitations to the successful accomplishment of this object The limitations of medicine are less numerous today than in the past, and many of the obstacles to success in the prevention of disease and the healing of the sick will be removed in the future

Medicine as a whole is not a science Of some branches which enter into it our knowledge is exact of others our information is theoretic, while every day adds to our knowledge and removes many obstacles from the path of progress The chemic laboratory and the microscope have done much and will do more to make medicine a science Progress in knowledge of chemistry and biology has been wonderful in the last twenty years and this knowledge has removed many of the limitations of medicine Strange as it may seem, the limitations of medicine which man is striving to remove, are due to man himself

Man is the highest type of animal, endowed with a mind capable of reason, and gifted with a means of communication with his fellows, and yet man is the very source of his own undoing The original man was doubtless perfect in mind and body, the master of all created things Like all organic life, his span was made up of periods of birth, growth maturity and decay He was doubtless able to combat his foes and sink at last, in the fulness of his years, into euthanasiac sleep The history of man, since the fall, is like the repeated pages of a book Vicious habits mark his footsteps, whether civilized or barbarian, his habits of work and of rest, his food and drink, are not rational, he contaminates the air he breathes, the water he drinks and the food he eats The water-sources and the earth, contaminated by man, become soil for the growth of the germs which infest and sicken him His contaminated body begets a prototype, imperfect in mind and body From the cradle to the grave a degenerate being, he fights against a mighty host, bred of his own shortcomings Most of the infectious and contagious diseases may be classed as preventable, most of them are filth diseases, and they can not exist in the presence of perfect cleanliness

A proper observation of hygienic rules relating to cleanliness of the person, of food, and of the water-supply, renders a population free of typhoid, cholera and other filth diseases The example of the city of Vienna is sufficient to prove this Previous to 1878, Vienna received its water supply from the Danube river, which was contaminated by the sewage of the city While using this water supply, Vienna suffered from the constant presence of typhoid fever, and cholera was a frequent visitor The World's exposition of 1873, at Vienna, was practically broken up because of a visitation of cholera and typhoid fever In 1878 Vienna's new aqueduct was completed which brought pure water from the Semmering pass in the Carpathian Alps, a distance of seventy odd miles From that time until the present, typhoid fever and cholera do not exist in Vienna, except as importations There has been but one exception to this—which emphasizes the lesson of the value of pure water I think it was in the year 1888 a break occurred in the Semmering aqueduct The old water-supply was temporarily used until the aqueduct was repaired Typhoid fever again promptly appeared in the city, and continued until the pure water was again supplied

Ideal sanitation would free the world of all diseases due to filth What prevents ideal sanitation? Many things ignorance of the people, both rich and poor educated and unread an ignorance of what is real cleanliness of mind and body and of the drink and food they take Health officers and family physicians teach in vain the value of cleanliness, the best methods of removing the contaminations of food and water, and the necessity of precautions in the presence of contagious diseases Ignorance, prejudice and a love of dirt are often difficult to overcome Sanitation has done much to overcome the evils of self contamination of water, milk and other food Sanitarians have not only the ignorance and prejudice of the people to overcome, but also the avarice of commerce Air pollution by smoke and odors sewage increase and consequent increased pollution from the by-products of packing-houses manufactories, etc food adulteration to meet competition in trade, are conditions not easily overcome, because of the political influence the dollar commands, especially in our municipal governments It is the influence of politics which prevents the enforcement of the laws which exist for our protection Politics and greed are synonymous terms Sanitation and the prevention of disease and of death are disregarded if the enforcement of the law should interefere with the official life, pleasures and emoluments of the politician

Politics in this country not only limits the enforcement of sanitary measures, but politics has had a blighting influence upon the advancement of medical education We have no law governing the conduct of medical schools or fixing a uniform standard of requirements for graduation, before beginning the practice of medicine Each State has its own medical law, and no two have like laws But few place the standard of requirements high, and most of them have very minor requirements In many States a charter for a medical school may be obtained for a small fee by any body of men who may please to originate a diploma factory In this city alone are twenty or more medical schools In this, as well as in some other municipal matters, Chicago leads the world Other States and other cities boast of medical colleges galore The most of these are private institutions owned partly or wholly by the teaching faculty The expenses of the institution are paid from the fees derived from the students The result in most cases is what one would expect Students unfit to study medicine are admitted to the schools, while inadequate facilities for teaching prevent the proper and thorough education of the student He goes forth with a diploma, which is equivalent to a license to practice in most States, for in but a few States is an examination to obtain a license necessary Thus, the profession is crowded with physicians who are not prepared for the work they should do, the people suffer in consequence and scientific advancement is retarded thereby Again, once a license is obtained, the State authorities are in most instances powerless to annul it, even if the holder thereof viciously prostitute his practice In practice the law says all physicians are equal who hold a license to practice The one may strive by all honest means to conscientiously help suffering humanity, the other may be a fiend on earth Murder and lesser sins may thus be lawfully committed The criminal may write the death certificate which affords safe burial of the victim All medical practitioners are, however, injured and their influence for good is lessened by every evil-doer in medicine Comment is unnecessary The influence of politics has more to do than any other one factor in the retardation of medical progress and in limiting the possibilities of medicine

Science is gradually and surely overcoming this evil In some States excellent laws have been established, requiring schools to admit only students who are properly prepared to study medicine The curriculum must contain certain branches and the course of study must extend over four years State examinations are also required for a license to practice, to which the applicant for examination is eligible only upon the evidence that he has taken a college medical course extending over a period of four years All of the States will eventually be forced into the plan, not by law but by the people, who are slowly awakening to a better knowledge of things medical Our State, county and city medical institutions are usually misgoverned by politics, and the patient and scientific medicine suffer in consequence The use of anatomic material is so restricted by law in some States that medical education suffers It is only since 1885 —twelve years—that anatomic study has been untrammeled in Illinois It will surprise many of you to know that previous to 1874 the law of this State made no provision for the use of anatomic material, and at the same time made it a criminal offense to dissect or experiment surgically upon cadavers illegally obtained

Vivisection has been a means of research which has so enriched our knowledge of physiology, has so perfected operations in surgery and so broadened our knowledge of pathology that thousands of human lives have been saved Nevertheless, antivivisectionists have secured the adoption of laws in some countries, and in some States so restricted vivisection as to retard medical progress The charge of cruelty to animals without material addition to our knowledge is not borne out by fact No scientist worthy of the name is cruel No scientist desires or asks for unrestricted and general vivisection By authorized teachers and honest searchers after truth, no cruelty will be practiced The knowledge gained will, in the vast future, be the means of saving the lives and relieving the sufferings of many times more human beings than the number of animals sacrificed In the meantime the antivivisectionists will perform a real service and save much brute suffering if they will turn their attention and influence to the relief of the overworked, underfed beasts of burden which drag overloaded drays, tramcars, and carrettes about the streets, and the time they may spend in protection of our birds from the plume hunter will not be lost

Our knowledge of pathology has been enormously increased in the last few years The cause of disease is very much better understood There is now no longer a reason for the existence of the many theories of medicine of former years The scientific physician whose knowledge of anatomy, chemistry, general biology, pathology and clinical medicine is ripe, will therefore recognize the disease and its cause, if it is known In the attempt to relieve the individual he will use every endeavor to remove the cause or to neutralize it He will use anything and everything which his knowledge and judgment dictate for the relief of the patient Pathies do not exist for him A liberal and exact education in the foundation studies of medicine, teaches him to take a broad-minded view of all things pertaining to medicine The adoption of a theory with a pathy attached necessarily includes belief in and practice of a narrow dogma Recovery of the acutely ill, is frequent enough under all sorts of management to afford argument of a specific cure all The man who practices a pathy burrows in a ditch, his horizon of observation becomes narrower as he digs The existence of pathies is an obstruction to medical progress To day there is no reason for the existence of the word "pathy" The properly educated man can no longer ignore the existence of disease and treat the symptoms only He cannot affirm that only vegetable medicines should be used and that all metallic medicines are poisonous He can not affirm that water alone should be used and that it may always be applied without danger He knows that manipulations alone can not remove a disease He knows that electricity is not understood therapeutically, and ascribes much of its value to its moral effect He recognizes the fact that certain conditions of the mind and body are relieved by hypnosis and by hypnotic suggestion, whether it be induced by the incantations of the Indian medicine man, the Buddhist and the black man of Africa, by the laying on of hands of the mesmerist and faith healer, or by the prayer of the Christian scientist He may be willing to use any or all of these methods, in the proper and few instances in which they may be indicated I will not say that the average physician who possesses all the qualifications of a scientific man will try to induce a cure by the laying-on of hands or by prayer He would probably think that equally good or better effects would be produced by a good dose of calomel

In the United States but little scientific medical work is done under National or State expense and control The medical department of the regular army encourages the medical officers to make scientific investigations, and furnishes the necessary apparatus for such research A few medical officers of the army have distinguished themselves by excellent scientific medical work

The navy has not recognized its medical officers by proper rank, nor has it encouraged or even given opportunity for scientific medical investigation The marine-hospital service is composed of excellent medical men Upon this department has devolved most of the National sanitary work of the last few years Its powers and possibilities are, however, limited

A few States have universities with medical departments, and in some of them excellent biologic and chemic work is done at the expense of the State Most of the States have boards of health, some of them composed of excellent medical men, clothed with sufficient power to be of benefit to the people The boards of health of many other States are usually composed of medical men selected for political reasons With every change of the political party in power, the members of the board, whether good or bad, are also changed The boards of health of many of the States have done excellent sanitary work Many have done much also to rid the medical profession of unqualified men, and in a measure, to elevate the standard of medical education, by recognizing the diplomas of only those medical schools that fulfilled the requirements of the boards in reference to the medical curriculum and time of study The full usefulness, however, of the State boards of health, of the teachers in the State universities, and of the medical officers of the army, the navy, and of the marine-hospital service is prevented by political and commercial interests, or by environment inimical to scientific work The greater part of the real scientific work in medicine in this country is done by individuals working privately at their own expense, or by teachers in institutions supported by the contributions of private citizens Most of the good scientific medical workers are poor, and are obliged to earn a living by professional practice, a time consuming impediment to proper scientific investigation A mind full of anxiety, burdened with the responsibility of a life threatened by disease, is not as clear or as capable of unraveling the problems of medical science as that of the man whose whole time may be given to a special line of research

In many foreign countries the governments recognize the scientific workers by paying them living salaries and by providing apparatus and opportunity for special lines of investigation In this country the government maintains an agricultural department for the protection of the products of the farm, and an interstate commerce commission for the purpose of regulating and equalizing the interchange of the commodities of the States This is done for commercial reasons There is a commissioner of pensions—the agent of the government in the financial interests of the soldier There is reason and justice in the maintenance of these departments But there is just as much, if not more, reason, for the existence of a National Commission of Health—a commission with power to regulate the sanitary problems of the country and to adjust matters medical between the States as fully and definitely as the interstate commerce commission performs its duties

In law a human life is worth $5000 to the State Why should the National government and the State not establish laboratories, or support those already established by private institutions, for the purpose of discovering the means of saving human life? Commercially a human life is worth more than an ox or a horse, and yet the government is more watchful of the health of animals which go to the slaughter-house, or of the possible contamination of the farms by Canadian thistles, or by an invasion of grasshoppers, than of its citizens The probable explanation is that corn, wheat and animals have an immediate visible commercial value, while a human life is the principal which earns only a small visible annual interest

The limitations of medicine in the management of acute infections and contagious diseases has always been great The success in the prevention of these diseases has been greater than in the healing of those already sick The discovery of bacteria and the relation they bear to the infectious and contagious diseases has afforded a still better means of prophylaxis and made a more rational treatment possible We have looked upon these diseases as self-limited in duration—self limited to accord with the life cycle of the invading germ The materia medica does not furnish us a drug which will cut short the disease The drug strong enough to kill the invading germ is equally deadly to the host We modify the course of the disease only We attempt to carry the patient through the illness by hygienic measures, simple food, bathing to modify fever, and by measures to support the patient until the invading army shall disappear Specific medication is of no value except in the malarial diseases and in syphilis This limitation of medicine is pronounced But the microscope and chemistry have discovered a principle which has already worked wonders in the cure of some of the infectious diseases—a principle which appears to be applicable to many if not all of the diseases due to bacteria It seems that bacteria not only secrete a poison which is the agent producing the symptoms of the patient, but that, like man, the germs are the source of their own undoing, for they also secrete or excrete or manufacture a substance which deals death to themselves and may also neutralize the disease producing poison in the patient The chemist has been able to isolate the toxin and the antitoxin in a few diseases Furthermore, it has been found that an individual treated with the antitoxin, not only more certainly recovers from a particular infection, but that a well individual treated with the antitoxin may be protected for a longer or shorter time from bacterial invasion, or at least from the disease producing toxin The accidental discovery by Jenner of the relation of cowpox to smallpox, and the resulting protection against smallpox by bovine vaccination, the further discoveries of Pasteur, of the possibilities of immunization of animals by inoculation with the attenuated virus of a disease, and the final brilliant discovery of, and the possibility of the utilization of, the respective antitoxins in the cure of, and in the prevention of, some of the infectious diseases, establishes a principle which is so important as to eclipse almost any other event in medical history. The brilliant results obtained in that dreaded disease, diphtheria, alone, from the application of this principle, is enough to fix it as a truth and justify us in the hope that it may be successfully applied in the near future to many other infectious diseases. In that branch of medicine classed as surgery, bacteriology made possible a knowledge of true cleanliness which has enabled the surgeon to invade with impunity, every part of the human body. Hence the horizon of surgery is wide and its limitations now are few.

I have said that many of the present limitations of medicine will disappear in the future. By what means may we hope to remove the obstructions to medical success? We can help to modify, and perhaps in the future hope to see the disappearance of, the abuses of medicine due to politics. We should exert ourselves to influence the establishment of a non-political, National Commission of Health, with power to regulate the study and the practice of medicine by a uniform law in all the States, with power to command the civil officers of the States in the enforcement of sanitation in relation to the contamination of food and drink, in the dissemination of contagious disease, etc. We should try to influence the government, both National and State, to recognize the scientific workers in medicine and the allied sciences by offering inducements in the way of honors and money reward for the discovery of facts which are of use in prolonging life and palliating suffering. A student who enters the field of medicine should be so thoroughly prepared, should have the proper facilities for study, and should give such time to the study of the fundamental branches and of the principles of medicine that he may command every possible means of prolonging life and relieving suffering. So prepared, he will embrace no dogma and recognize no pathy. A physician, he will command the respect and love of the people, who will listen to and heed his advice and instruction. Every physician so educated will exert a wide influence in helping to remove the conditions of the people which tend to limit the usefulness of medicine.

In closing, let me say a few words of the possibilities and the needs of this school. If we add to the great influence which this school possesses because of the reputation gained by fifty years of progressive improvement in medical work, the advantage which must result from the affiliation with the great University of Chicago, we may hope for the ideal in medical education. The broad-minded policy of the University will be admirably executed by the splendid mind of the man who conceived the plan. Over the whole Northwest are schools academies and colleges that have shaped their courses of study to correspond with the curriculum of the University. Students will be piloted through the preparatory school the academy, the college and the University, their minds moulded, trained and disciplined with a forethought of the final life-work of the individual. So prepared, a student will begin the study of medicine. The foundation studies—chemistry, physiology, general biology, anatomy, pathology, pharmacology and materia medica—will either be completed or the principles thereof will be mastered in the first two years of medical study. Then must come the application of the knowledge possessed of the foundation branches to the study of disease in the living and the dead. In hospitals and dispensaries, in chemic and pathologic laboratories, must the student labor to recognize disease by the phenomena termed symptoms, physical signs, and by the changes which occur in the tissues, the blood, and the various secretions and excretions of the body in disease.

To accomplish ideal work in the last two or three years of a medical college course, it is necessary to have at hand a plentiful amount of material with which to work. Not only must the amount of material be sufficient, but it must be situated, in reference to facility of use, that all that is possible may be obtained from it. It is, therefore, necessary that proper buildings be had for both dispensary and hospital patients. The dispensary must be a clinical building, so arranged with rooms for clinical examination and for laboratory research, that all students may come in direct contact with the patient, and be enabled to make the examinations I have named above. A free bed hospital should also be accessible, to furnish examples of the acute and severer forms of disease, with laboratories and apparatus for thorough examination of everything of which analysis is necessary, in the recognition of disease and in the study of the action of remedies used in the attempt to heal. Facilities should be afforded, in an annex or building closely adjacent to the hospital, for the study of morbid anatomy. Here, under the proper direction of a pathologist, the student should be enabled to carry on the more practical study of pathology, the principles of which he learned in his first two years of medical college work. Here he should be able to trace the relation of the morbid changes to the symptoms, to the physical signs and to the alteration of the secretions and excretions of the body, which he was able to observe in the wards of the hospital. By this means he will be able, not only to understand the principles of the various subjects of medicine, when separately considered, but also their intimate relationship to each other. It is not too much to hope that this institution shall in the near future have a clinical building with all of the modern conveniences which architecture can furnish, including laboratories, with every means which shall afford the surest recognition of disease, and thus give greater comfort and surer means of relief to the sick. It is absolutely necessary that this school shall have a free private hospital governed entirely by its faculty, with all of the laboratories for the recognition of disease, and the examination of the morbid changes which occur in the human body. With a clinical building, and with a hospital such as I have attempted to describe so briefly, this school, possessing as it does, the present means of obtaining students thoroughly fitted for the study of medicine, and with almost perfect facilities for the study of the fundamental branches of medicine, will soon attain an ideal medical course. With such an institution in the West, medical education will be so stimulated that other institutions, even though they have lesser facilities, will attempt to keep in line.

The medical man of the future will thus be, not only better prepared to meet, but will also be better equipped to further lessen the limitations of medicine

THE ESTIMATION OF URIC ACID IN URINE

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10 1898

BY HENRY C C MAISCH, PH D

PHILADELPHIA PA

While connected with the Stetson Laboratory of Hygiene, my attention was called to the fact that it was desirable to make a study of the conditions under which there was an increased, and other cases in which there was a decreased, elimination of uric acid Intimately associated with this would be a physiologic study of tissues and probably also cell metabolism, in other words, determining the place occupied by uric acid in the chemistry of the animal body The purely physiologic study being out of my line, I determined, on the recommendation of two of my former colleagues, Dr Judson Daland and Dr Frank Massey, to take up the purely chemic side of the question

The first step in the investigation would be to determine on a method for the estimation of uric acid which would be comparatively simple in its application and which would in the different operations be accompanied with the fewest sources of error In looking over the literature on the subject we found many contradictory statements as to the accuracy of one and the same method It is possible that a method under certain conditions will give accurate or fairly accurate results, while in other cases the same process will give results which vary considerably from the truth It is not absolutely necessary for our purpose to study the cause of variation, but an examination of the methods under various conditions would be sufficient and from the data thus obtained determine on a method which would be used in the principal investigation

It would seem fairly simple to determine on an accurate method by taking the simplest case possible and trying the different processes on this one I refer here to making a standard solution of uric acid of known purity and applying the different tests But from the very start we have to contend with the ready decomposition of uric acid while in solution It is a well known fact that uric acid in an alkaline liquid is more or less rapidly decomposed into a number of distinct compounds which form at the end carbon dioxid, ammonia and oxalic acid This decomposition is due to oxidation and hydration on the addition of oxygen and hydrogen in the form of water, H_2O, to the molecule of uric acid, $C_5H_4N_4O_3$ A similar change takes place also in urine when exposed to the air without sterilization or preservation in some manner or other It is necessary, therefore, that a urine should be examined for uric acid as soon as possible after voidance

The results obtained in estimating the amount of uric acid in a simple solution of uric acid can not be taken as applying with like force to the estimation in urine as I will show later on The difference is due very likely in the organic and inorganic compounds found in the urine, which among other properties show a peculiar solvent action toward the urates, this peculiar behavior residing principally in the phosphates and the urea

In estimating uric acid in a sample of urine it is decidedly preferable to use that passed in twenty-four hours, as this alone will give a criterion as to quantity and assist very materially in computing the results obtained It is possible that when the urine usually passed is rather concentrated under the influence of alcoholic beverages, the quantity of water excreted is materially increased, the urine becomes diluted, and if a sample of this latter urine is used the proportion of uric acid is diminished

For the work in hand it was necessary to apply the tests to the same urine throughout, but it being impossible to obtain the necessary quantity from one person at one time, it was thought best to collect a lot of urine from different persons and then make the estimations on the collective urine I therefore sent a large vessel to one of the departments of the J B Stetson hat factory, and had it filled without paying any attention as to whether persons using the same were in health or under treatment for any disease The quantity obtained amounted to about four gallons, and was furnished by eighty persons

The urine showed the specific gravity of 1 021, and contained neither sugar nor albumin Before taking the quantity for each estimation the urine was thoroughly mixed each time In reporting on the different methods I will begin with the one first recommended, and which to all appearances would be the simplest, taking into consideration the slight solubility of the uric acid From this I will continue through the other methods applied, becoming gradually more difficult in application, and ending with the process which I have adopted as being the one which unites accuracy and ready applicability

The first method we would have to consider is that of Heintz, in which the uric acid is set free by means of hydrochloric or other acid, and after standing for at least forty eight hours, collecting the precipitated uric acid and weighing When applying the rules as they pertain to ordinary solutions it would be expected that only a small quantity of hydrochloric acid would be necessary to complete the precipitation It has, however, been shown that a solution of urea has a solvent action on uric acid, probably forming therewith a chemic compound which, however, is not soluble in a highly acid medium It is, therefore, usual to add 20 c c of strong hydrochloric acid to 100 c c urine, which is a considerable excess, but even with this excess a complete precipitation does not take place, uric acid being soluble in water in the proportion of 1 to 16000 According to this the correction would only be slight, and it is given as 0 0038 gm for each 100 c c of liquid in use *Salkowski found* that after treating 200 c c of urine as above, he could still isolate from the filtrate thus obtained from 0 014 to 0 07 gm of uric acid by supersaturating with ammonia and precipitating with ammoniac silver nitrate solution I applied this test with hydrochloric acid and also with acetic acid, and found

With HCl 1, 0353 2, 0349 3 0369—mean 0 0357 per cent.
With $C_2H_4O_2$, 1, 0338 2 0375, 3 0407—mean 0 0373 per cent.

What surprised me somewhat was that I obtained with the acetic acid macroscopic crystals of uric acid which at first were perfectly transparent and of a reddish color, but on drying became opaque

The second method is that of Guerin and Thorion, who propose to precipitate the uric acid as the magnesium ammonium urate—to which they ascribe the formula $(C_5H_2N_4O_3H)_{10}(NH_4)_8 Mg+45H_2O$—by means of the magnesia mixture as used in phosphoric acid estimations It would be impossible to simply filter off the precipitate and regard it as this compound, on account of the magnesium ammonium phosphate also formed They therefore incinerate the precipitate, *forming magnesium pyrophosphate and magnesium* oxid, and estimate the amount of the latter produced The magnesium oxid is formed from the uric acid compound, as the only incombustible portion present is the magnesium

In applying this test 100 c c urine were used, and after incinerating the precipitate, the amount of magnesium was estimated volumetrically The residue was taken up with 25 c c decinormal sulphuric acid, and when titrating with decinormal sodium hydrate it was found that it required 22 c c to bring the liquid to neutrality, leaving 3 c c saturated by the magnesium

3 c c , n/10 H_2SO_4=0 014673 gm H_2SO_4=0 003645 gm Mg

According to the formula we have 10 molecules of uric acid (167 8) to one atom of magnesium (24 3), and consequently we have the proportion

24 3 003 645 x (24684 gm uric acid)

In a second determination the result was even more unsatisfactory The quantity of decinormal sulphuric acid saturated by the magnesium amounted to 4 2 c c , consequently giving even a higher result

Third Uric acic forms an insoluble barium salt, and it is on this property that Geelmuyam bases his method He adds sodium hydrate to the urine in such a quantity that litmus paper remains blue when dry and then precipitates with barium chlorid Besides the barium urate he also has formed here the barium sulphate, and to separate the two he boils the washed precipitate with dilute hydrochlorid acid, filters off the barium sulphate while hot, and evaporates the filtrate to a smaller bulk On standing, the uric acid separates, is collected on a filter, washed, dried and weighed The results obtained with this method are

1, 0 0425 , 2, 0 0439 , 3, 0 0393—*mean* 0 0419 per cent

With this urine the results were fairly satisfactory, but on applying it in another series the amount of crystals obtained was so small that they were not weighed

Fourth On boiling urine which does not contain any sugar with Fehling's test, we find a decolorization and a precipitation of flocculent masses—cuprous urate—part of the uric acid reducing the copper to the cuprous oxid, which then combines with the uric acid present, forming the cuprous urate Arthaud and Butte add the copper in the form of cuprous hyposulphite to the urine and precipitate the cuprous waste direct without losing any of the uric acid through oxidation They have arranged it as a volumetric method, using the following solutions

1 Copper sulphate, 14 84 gm , tartaric acid, trace (I use, following Ducong, five drops of sulphuric acid), distilled water sufficient to make 1000 c c

2 Sodium hyposulphite, 80 gm , rochelle salt, 160 gm , carbolic acid, 5 drops , distilled water sufficient to make 1000 c c

For estimating, 2 parts of 1 are mixed with 8 parts of 2, giving a solution of which 10 c c precipitate 2 cgm uric acid

The manner of applying this test is as follows 100 c c urine are made alkaline with sodium carbonate, warmed to precipitate the phosphates and then filtered A portion equivalent to 50 c c urine is treated with the above solution, drop by drop, until no more precipitation occurs As it is very difficult to notice when sufficient of the cuprous solution has been added, the authors propose a few methods of determining the end reaction The first and simplest, but not very satisfactory, method is to filter off a small quantity and add a few drops to it from the burette, when, if no precipitation occurs, the titration is complete The second method depends on oxidizing a possible excess of the copper to the cupric state and noticing the color produced with ammonia, they propose to take some of the above filtrate, add ammonia to it and shake in a test tube, permitting the oxidation to be done by the oxygen of the enclosed air The third and preferable indicator is a 10 per cent solution of sodium or potassium xanthogenate By adding a drop of the filtrate to this solution an excess of copper shows itself by the production of a yellow color

The first series in which this method was applied gave the following results, determining the end reaction by the precipitation method

1 Required 20 c c for 50 c c , equivalent to 0 04 gm in 50 , 080 gm in 100 c c

2 Required 21 c c for 50 c c , equivalent to 0 042 gm in 59 , 082 gm in 100 c c

3 Required 16 5 c c for 50 c c , equivalent to 0 033 gm in 50 , 066 gm in 100 c c

In this last the ammonia method was tried, but did not prove to be satisfactory Having some of the liquid remaining it was thought best to try the other indicator, potassium xanthogenate With this, results were obtained more closely conforming to those obtained with other methods

1 Required 12 84 c c for 50 c c , equivalent to 0 02568 gm in 50 c c , 0 05136 gm in 100 c c

2 Required 13 2 c c for 50 c c , equivalent to 0 0264 gm in 50 c c , 0 0528 gm in 100 c c

3 Required 10 8 c c for 50 c c , equivalent to 0 0216 gm in 50 c c , 0 0432 gm in 100 c c

With sufficient practice this method may be made to do the work admirably, but the objection to this, like all processes requiring volumetric solutions, is the extreme care and exactness necessary in its use

Fifth Uric acid, like many organic compounds, will take up a certain amount of iodin, or in other words, reduce a certain quantity of iodin solution I Kreidl endeavors to make use of this property of uric acid in estimating its quantity He draws attention to one peculiarity in this respect, viz the variation of the power of reduction according to the length of time the uric acid and the iodin solutions were in contact If standing only a short time the amount of iodin consumed appears to be greater than it does at the end of three quarters of an hour, at which time 2 3 atoms of iodin correspond to one molecule of uric acid The application *of this process is as follows* A moderate excess of normal potassium hydrate solution is added to the urine and followed by a considerable excess of thirtieth-normal iodin solution After standing *three-quarters of an hour the liquid is acidi*fied with hydrochloric acid, some starch solution added, and the excess of iodin titrated with thirtieth-normal sodium thiosulphate (hyposulphite)

The *results obtained by this method, paying strict* attention as to time for standing, were as follows

1 Consumed 39 5 c c iodin solution, corresponding to 0727 gm in 100 c c

2 Consumed 39 c c iodin solution, corresponding to 0717 gm in 100 c c

3 Consumed 38 5 c c iodin solution, corresponding to 0673 gm in 100 c c

Comparing the results thus obtained showed them to be higher than by the other methods The titration being made in the order here given showed that the time allowed is too short for the proportion as stated by Kreidl It is possible also that exposure to light has a reducing effect on the iodin solution, which disappeared Iodin would consequently be estimated as being caused by uric acid On the whole, the method is unsatisfactory, principally on account of the instability of the solutions used for titrating

Sixth The inaccuracy of the Heintz method was first shown by Salkowski by precipitating the balance of the uric acid with ammoniacal silver nitrate solution On this he based this first method, estimating the uric acid with hydrochlorid acid and the silver solution Ludwig simplified this by simply using the latter, and following him, Salkowski proposed a similar but more round-about process The Ludwig or as it is called, Salkowski-Ludwig, method is possibly the one most applied, and is here used The solutions required are

Ammoniacal silver solution —26 gm silver nitrate are dissolved in sufficient water, then ammonia water added to dissolve the precipitate first formed, and lastly the whole diluted to 1000 c c with water

Magnesia mixture —100 gm magnesium chlorid crystals are dissolved in the necessary amount of water, ammonia added in excess, and lastly sufficient ammonium chlorid to dissolve the precipitate The solution is then diluted with water to make 1000 c c

Solution of an alkaline hydrogen sulphid —15 gm potassium hydrate or 10 gm sodium hydrate are dissolved in sufficient water to make 1000 c c One-half of this solution is saturated with hydrogen sulphid and the two again mixed

The estimation is made in the following manner· For every 100 c c urine taken mix 10 c c each of the ammoniacal silver solution and the magnesia mixture and sufficient ammonia to dissolve the precipitated silver chlorid This solution is then added to the urine and the whole thoroughly shaken After standing about one hour the precipitate is collected on a filter, and washed two or three times with water to which a few drops of ammonia have been added During this time we have taken 10 c c of the third solution, mixed it with an equal volume of water, and heated to boiling This hot solution is then poured on the filter, which has been placed in a beaker, 40 c c hot water added, and the whole then heated to boiling The mixture is stirred repeatedly while cooling and filtered into a porcelain dish, the filter being washed two or three times with water After slightly acidifying with hydrochloric acid the filtrate is evaporated to 10 or 15 c c and allowed to cool The uric acid as thus obtained usually contains some sulphur, which must be removed After collecting the precipitate on a filter it is washed with water, alcohol, ether, carbon disulphid, and this then removed with ether, the filter dried and then weighed

In the experiments I used 200 c c urine for each trial and obtained these results

1 0793 in 200 c c. , 03965 in 100 c c
2 0936 in 200 c c , 0468 in 100 c c
3 0958 in 200 c.c. , 0479 in 100 c.c

The cause of the first result of the series being so low was that a portion of the liquid was lost

Seventh As shown above, working by Salkowski-Ludwig, the uric acid is estimated, but there is a possibility of the same reaction being made use of in another manner and arriving at a result which conforms fairly well with the above Haykraft's method depends on a consideration like this, and is based on the supposition that the precipitate, as obtained by the above method, is of constant composition, containing one atom of silver for every molecule of uric acid It must be possible to estimate the amount of uric acid present by determining the amount of silver in the precipitate Haykraft proposes to do this as follows The precipitate, as obtained by the Salkowski-Ludwig method, in the urine is allowed to settle and the clear liquid is run through a glass wool filter Before pouring on the precipitate the surface of the filter is covered with lumps of sodium bicarbonate and on top of this the balance of the liquid, with the precipitate, is poured The vessel in which the precipitation was carried on, and also the filter, are washed with ammoniacal water until the filtrate gives no precipitate either with silver nitrate and nitric acid, nor with hydrochloric acid The residue on the filter is then dissolved in concentrated nitric acid and titrated with a solution of ammonium sulphocyanate, using a solution of ferric alum as an indicator The solution of the sulphocyanate is of such a strength that 1 c c is equivalent to 1 c c 1/50 normal silver nitrate solution and represents then 3 36 mg uric acid

The results obtained by this method did not prove so satisfactory, being considerably higher than those obtained by the other

1 1213 gm in 200 c c , 0606 gm in 100 c c
2 1391 gm in 200 c c , 0695 gm in 100 c c
3 1509 gm in 200 c c , 0754 gm in 100 c c

An objection to this method which, however, is good in theory, is that there is a certain amount of reduction of some silver compound other than that of uric acid This silver compound is not washed out with the ammoniacal water, but will go into solution with the nitric acid, and consequently increase the amount of silver reckoned as combined with the uric acid Furthermore, a filter pump is a necessity in carrying out this process, otherwise a much larger quantity of a black compound will be formed

Eighth Some years ago Fokker made use of the slight solubility of the ammonium urate for estimating the amount of the uric acid The want of accuracy induced Salkowski to alter the process to a certain extent This altered process is as follows 200 c c urine is made alkaline with 20 c c solution of sodium carbonate and after one hour 20 c c saturated solution of ammonium chlorid is added to it This mixture is allowed to stand for forty-eight hours, then the precipitate collected on a filter and washed two or three times The precipitate is then repeatedly treated while in the funnel with dilute hydrochloric acid until all the ammonium urate is decomposed The filtrate is then set aside for six hours and the uric acid which has separated transferred to the remainder of the acid on the filter, which is then washed first with 30 c c of water and lastly with alcohol until the acid reaction has disappeared The acid can now be weighed, but a correction of 0 03 gms must be added to obtain a definite result

The objection to this process is that the ammonium urate is not entirely insoluble in the urine, varying amounts remaining in solution Another objection is the time it takes to finish one estimation, taking in hispidus contains only about two-thirds as much The amount of contained strophanthin is partly dependent upon climatic conditions It is a well-known fact that the physiologic activity of digitalis leaves varies within wide limits from year to year

Strophanthin, having the formula $C_{21}H_{48}O_{10}$ (Arnaud), is believed to be the only active constituent of strophanthus hispidus and strophanthus Kombé Some investigators, however, claim that strophanthidin also is found Fraser and others oppose this view, believing that strophanthidin is merely a decomposition product of strophanthin Strophanthin, like other glucosides, is easily decomposed by acids It is readily soluble in water and alcohol, but almost insoluble in ether and chloroform Pure or impure strophanthin, or pharmaceutic preparations containing the glucoside, when brought in contact with sulphuric acid, a trace of ferric chlorid being present, yield a bright green color This reaction is not conclusive, however, since ouabain can not be recognized in the presence of strophanthin Holmes who has given this point much attention, claims that only by purchasing the seeds in the follicle and testing a seed from each follicle, can a reliable preparation of strophanthus be made An assay based on the amount of extractive contained in a given tincture of strophanthus, or other preparations of the heart tonic is of little value to the physician, since the extractives consist largely of chlorophyll and other inert substances

After a careful consideration of the difficulties preventing a chemic assay of the heart tonics, and of the great importance to the medical profession of some means of standardizing them, I decided to experiment on living animals, believing that data might be obtained whereby the physiologic activity of the crude drug, its pharmaceutic preparations and active constituents might be ascertained Since it could not be taken for granted that every sample of strophanthus seeds or digitalis found on the market was active, it eemed best to adopt methods for determining first of all, whether the specific action of the heart tonics was manifested by the sample of drug, and second, to find methods for standardizing them

QUALITATIVE REACTIONS

Very extensive pharmacologic researches have shown that the several heart tonics act in much the same manner, differing mainly in degree, upon the factors concerned in the maintenance of the circulation of the blood The most important phenomena observed are slowing and strengthening of the heart-beats and increased blood-pressure I believe only two series of experiments are necessary in order to show whether a given sample of drug possesses the specific action desired, viz, the application of a solution of the crude drug or active constituent to the laid-bare frog's heart, noting the slowed rhythm, the less and less perfect diastole, increased systole and finally, systolic standstill of the ventricle, and the intravenous injection of such solutions into dogs or rabbits, observing the variations in blood-pressure and heart beats, as shown by graphic tracings recorded on the kymograph Other reactions might be obtained in addition, but are not necessary The physiologic activity of each sample of drug examined should be compared with a standard sample of known strength

QUANTITATIVE ASSAY

A quantitative estimation by pharmacologic methods of the activity of the heart tonics is a much more difficult problem than is a qualitative assay Many series of experiments were necessary in order to decide what method or methods were best suited for this work Too great variation was exhibited in the results obtained from blood-pressure experiments on dogs, rabbits, etc, and such experiments are, moreover, quite complicated and difficult to carry out I found that fairly accurate data could be obtained from the application of a solution containing strophanthin, digitalin, etc, to the laid-bare frog's heart, comparing the action of the drug thus tested with that of a sample of known strength This method, however, was finally abandoned for a simpler one, which gives much better results It seemed to me quite probable that the strength of the heart tonics could be determined from their killing power when administered to the lower animals Accordingly, rabbits, guinea pigs, rats, frogs, etc, were employed for determining the minimum fatal dose of the drug I finally chose frogs as being best adapted for this purpose Different species of frogs vary considerably in reaction to the poisons, but the same species behave much alike I have found it best to employ frogs of a nearly uniform size for the standardization of any particular tonic Since it is impossible to obtain on the market frogs of exactly the same size, it is best when one has a large number of samples to standardize, to have the frogs separated into lots by weight, those in each lot not varying over three grams, then we can use those weighing 10 to 13 grams for strophanthin, those weighing 14 to 17 grams for tincture strophanthus, those of 18 to 21 grams for tincture digitalis, etc Frogs weighing less than 30 grams can be obtained at a very reasonable price from fishermen, as they are too small for the table However, it is necessary that from the moment of capture they be handled with great care and kept in wet moss, etc, until they arrive at the laboratory, when they should be at once transferred to suitable ponds

The method of administering the poisons and observing results may be briefly stated as follows Dissolve the strophanthin, or tincture of strophanthus, in normal saline solution The strength of the medicated solution should be such that the total quantity to be injected shall not exceed 5 c c The fluid should be measured by means of very slender pipettes, graduated into hundredths, into round-bottomed capsules of about 1 c c capacity, from which the last drop may be taken up in a narrow pipette having a long slender point, and the injection then made through the frog's mouth into the abdominal lymph-sac Great care should be taken not to puncture the skin, as this will allow a portion of the injected fluid to leak out After injection the frogs should be placed in wide-mouthed frog glasses, the plates containing about a quarter of an inch of water It will be necessary to inject several series of about five frogs each for each sample of the drug to be assayed, a first series to be injected with drug of known standard strength After testing a large number of tinctures of strophanthus I found that *0 00015 c c per gram body-weight, represented* fairly well the toxic activities of an average sample of tincture prepared from strophanthus (Kombe)

The minimum fatal dose of tinctures strophanthus prepared from various lots of drug obtained from the American market was found to be as follows

1	00015	4	00012
2	00026	5	00013
3	00015	6	00015

7	00010	11	00016
8	00015	12	00015
9	00022	13	00025
10	00017	14	00033

The several tinctures were prepared by one process and with the same menstruum

The second series are to be injected with doses varying considerably in size The third series are to be injected after the approximate dosē of poison has been found from the second series From the third series we may almost surely fix the minimum dose A fourth series should finally be injected, which will fix the limits of strength very closely The minimum fatal dose should kill at least three frogs out of five If a less number die it is best to inject another series with doses one point greater

One very important advantage of the method above outlined for the assay of the heart tonics, is the fact that various kinds and sizes of frogs may be employed at any season of the year, the only essential being that at the time the assay is made the standard and unstandardized preparations should be tested at the same time, the frogs being of exactly the same species and kept under exactly the same conditions, comparative results only being necessary, since the standard solution maintains its activity almost entirely unimpaired, as shown by tables III A and III B

A standard tincture of strophanthus retains its strength very well, as is shown by the following tests, made on the first standard tincture I employed

TABLE III A.

	Minimum fatal dose
July 6, 1897	00015
Oct 19 1897	00015+
Dec 23, 1897	00015
Feb 23, 1898	00015—
April 25, 1898	00015

The loss in strength was so little in nearly one year that it came within the limits of error Similar results are observed in regard to the permanence of a concentrated tincture of strophanthus

TABLE III B

	Minimum fatal dose
July 28, 1897	0000037
Nov 10, 1897	0000037

The ease with which we may always keep on hand a standard preparation of the heart tonics greatly facilitates the carrying out of the test and the accuracy of the results as compared with those obtainable with diphtheria toxin or antitoxin, both of which latter lose their active properties in a comparatively short time

TABLE IV

		Minimum fatal dose
Strophanthin	No 1	000009
"	No 2	000001
"	No 3	000001
"	No 4	00000062
"	No 5	0000001
"	No 6	0000001

The foregoing table shows the variation in the strength of different samples of strophanthin which were obtained from three of the best manufacturing chemists in the world They were supposed to be pure strophanthin, yet one sample is ninety times as strong as another, the others varying between these limits The digitalins also vary greatly in strength, but much less than strophanthin Both strophanthin and digitalin are given daily in tablet or pill form, the amount of active ingredients being apportioned by weight A splendid opportunity for a sudden termination of a favorably progressing heart disease, should the patient be obliged to have his prescription refilled from a fresh bottle The only way that such remedies can be taken with any degree of safety is to have them prepared from stock of known physiologic strength I will not dwell upon this subject longer at present, but desire to say in conclusion that the method of assay herein described is put forth in the hope that others will experiment along this line I do not claim it is the best method of pharmacologic assay that may be devised for this group of therapeutic agents, since I have not yet satisfied myself that it is applicable to every one of the members of the group, but I do claim that some method of assay should be employed

---

THE GREAT THERAPEUTIC IMPORTANCE OF A RATIONAL ADAPTATION OF CATHARTICS TO THE PHYSIOLOGIC FUNCTIONS OF THE GASTRO-INTESTINAL SYSTEM

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10, 1898

BY E D McDANIEL, M D

MOBILE ALA

The skin or external integument may at first thought seem to constitute a much greater surface than the more hidden part known as the internal integument, but the latter really represents much the greater area This is due to the smaller number, size and depth of the openings and duplicatures existing on the skin for absorbent, secretory and excretory purposes, while the internal integument possesses much more numerous and larger duplicatures, with more numerous, larger and longer glandular and absorbent structures The part of the internal integument that pertains to, the respiratory system being excepted, the remainder, reaching from the margin of the lips to the verge of the anus, constitutes, with its appertaining or collatitious viscera, what is designated in this paper "the gastro-intestinal system"

By function is to be understood a work or process accomplished in a living part by the operation of chemical, mechanical and vital laws We shall therefore regard function as synonymous with process Our allotted time would not suffice for a consideration of all the processes or functions that may take place in the long course and many parts of the gastro intestinal system Many such processes may be yet undiscovered and none of them, in the present state of physiology, may be fully understood Our task will be more feasible, more simple and more useful if we restrict our consideration to six leading processes whose existence may be assumed to be admitted These processes are the digestive, the secretory, the absorbent, the excretory, the peristaltic and the disinfective It will doubtless be further granted that these processes, when existing in true relationship, regularity and harmony, contribute a large and essential contingent to human health that whenever their correlation is disturbed or destroyed there follows a corresponding amount of disease that this disease with its cause or causes demands remedy, and that a proper application of the needed remedy constitutes the proper therapeutics Moreover, it seems obvious that whatsoever process or processes—whether digestive, secretory, absorbent, excretory, peristaltic or disinfective—be primarily or paramountly disordered in any actual case, the same must indicate the special remedy or combination of remedies needed in that case

As analogy easily places all classes of remedies under this general rule, and requires of physicians the use of a like wholesome discrimination in the employment of all remedies, our thesis, abstractly viewed may be regarded as established, and the query may be raised Why is it proposed to apply to the class of cathartics alone a rule applicable to all classes of remedies? Or why is not the rational adaptation of other classes of remedies as much to be enjoined as that of cathartics? The answer is clear and easy The fact that the rule applies to all classes of remedies does not remove all cause for specially emphasizing it in regard to cathartics, but really furnishes strong reason for its rigorous enforcement in the use of remedies so continually resorted to, so speedy, and so satisfactory in action and so nearly unapproachable in most essential, extensive and beneficial results

The contents of the gastro-intestinal canal are related to the body as the soil is to the plant, and as the life, growth, and vigor of the plant depend essentially upon the nature and condition of the soil, so do the life and health of human beings depend upon the character and management of the contents of the alimentary canal And as the cultivation of the soil is tantamount to the cultivation of the plant, so the wise management of the contents of the gastro intestinal system is a leading instrumentality in the conservation of human health, and while, in this work, the worth of a proper diet, control of the appetite, occasional fasting, massage, etc, are recognized helps, yet in all urgent or grave conditions, the main dependence must be upon the more thorough work of cathartics or purgatives, which are here used as synonymous with each other, and may be defined as that class of remedies therapeutically used to cleanse the gastro intestinal system by increasing the frequency, copiousness and fluidity of the alvine discharges and otherwise modifying the quality of these discharges In whatever mode administered, whether orally, hypodermically, epidermically, by enema or by suppository, they serve directly or remotely, primarily or secondarily, to unload the bowels, to deplete the general system, to promote absorption, to produce revulsion, to eliminate morbific matters from the blood and tissues, to modify favorably local action by stimulation, sedation or alteration With so wonderful a range and power of action, it is no wonder that cathartics are indispensable in virtually all diseased conditions as

1 Fevers—intermittent, remittent, continued, eruptive, ephemeral, or traumatic
2 Inflammation—acute, chronic, cerebral, thoracic, abdominal, pelvic, or neuritic,
3 Constipation—acute or chronic, colic of the various kinds, dyspepsia
4 Dysentery and diarrhea
5 Hemorrhages—active and passive epistaxis, hematemesis, hemorrhoidal menorrhagia, metrorrhagia, hematuria
6 Neurotic disorders—hysteria, chorea, epilepsy, tetany, neuralgia, lumbago and sciatica
7 Dropsies—active and passive, acute and chronic
8 Intestinal worms, all varieties
9 Intestinal obstruction—impacted rectum, impacted colon
10 All diatheses, cachexiæ, and dyscrasiæ, and the hosts of skin diseases

Thus the cleansing action of cathartics, beginning primarily and conspicuously in the gastro-intestinal system, proceeds steadily and surely advancing step by step and from part to part, until it pervades the entire body, penetrating even the external integument and showing itself indispensable in the treatment of all cutaneous diseases It must, therefore, be clear that without the great gastro-intestinal system, *on and through which to act*, and the great class of cathartics *with which to act*, the medicine of the past could not have made its great history, the medicine of the present would not possess its mighty power, and the medicine of the future could never accomplish its meditated glorious projects

May not the great body of representative physicians congregated here today, within one hundred miles of a peak from whose sublime summit one can look down in rapture upon a panorama of forty thousand square miles, in full view, around and below, be pardoned if, centering their thoughts upon the one predominant basic class of remedies and realizing its crowning pre-eminence, they seem to see all other classes as lying far away and far below? And knowing that man's nature is such that, in the end, he accomplishes most by doing one thing at a time, may we not hope that while exercising careful and constant discrimination in the use of that class of remedies which most contributes to our satisfaction, our success, our usefulness and our reputation, we may be making a forward step in a happy habit of like care and discrimination in the use of other classes of remedies?

It may be well here to point out the difference between *rational medicine* and the *rational adaptation of medicine* Unfortunately an invidious controversy has sprung up in favor of what claims to be *rational* as opposed to *empiric* medicine And in the literature of the controversy the words "rational" and "empiric" are used, each in two different senses In one of these senses 'empiric" implies recklessness, ignorance and aimlessness, in the other, confidence of cure based solely on former experience or observation of cure of like cases by the same remedy, without any comprehension of the mode of cure So the word "rational" as opposed to "empiric" generally refers to the effects of remedial agents upon healthy human beings or upon lower animals, these effects, though admitted to be purely physiologic, being considered a basis upon which to found the expectation of curative action in disease All knowledge, in whatever justifiable way acquired, is useful and desirable, but as all actions and reactions in nature are the outcome of conditions and relations and must vary accordingly, the only sure and reliable basis of therapeutics is clinical experience, or *trial upon the sick*, and therefore, in its origin, *empiric* Remedies suggested by physiologic experiments, by sanguine reports of credulous or interested persons, by extensive popular use, by aboriginal tradition or other similar insufficient grounds, need not always be sneered at, but must be first tried in the great court of clinical experience before they deserve to be duly accredited The rational medicine recognized in this paper is that which, tested for an adequate time by a satisfactory number of competent persons, on multitudes of patients, in varied localities and climates, and in ascertained doses and modes of administration, has been found to relieve the sick most surely, most quickly, most pleasantly and most permanently And the selection and use of individual medicines and methods so tested, and their careful adaptation to each varied case and condition is what is meant by *rational adaptation*

Among all the vast multitudes of human beings that have lived, that now live, or that ever will live, no two faces have ever been found, are now found, or ever will be found, with every feature, part and point precisely alike, so, and much more, in the relatively small number of cathartics, it can not be expected that any two of the number will be found completely one in effect Indeed, there are not now known, in the whole compass of materia medica, any two different substances of perfectly identical action In this, no doubt, is found the reason why, in our generation of authors, the alphabetic order is so much followed in the text-books on materia medica—any satisfactory classification being despaired of—and the names of the classes used being compared to "a row of pegs on which to hang ideas" But class names and subclass names of remedies, indicative of their most conspicuous, constant and regular action, are as old as medical literature and will never cease to be used in our language, our colleges, our hospitals and our homes "Cathartics" or "purgatives" will continue to be the name of a class, and its subclasses will be differentiated as laxatives, aperients, salines, cholagogues, hydragogues, drastics, etc, according to the characteristic degree or variety of action produced Their rational adaptation to the functions of the gastro-intestinal system will consist in such selection, combination and employment as may best tend to secure the desired degree or variety of action

It may be regarded as obvious that *cathartics must counteract and diminish the digestive and absorptive processes* by accelerating the contents of the alimentary canal in their course, so as to allow insufficient time for these processes to be duly accomplished It must also be obvious that *they must increase secretion, excretion and peristalsis*, as the increased size, number, frequency, fluidity, and other characteristics of the alvine discharges clearly demonstrate

It is hoped that sufficient has now been said to lead the practicing physician to consider the gastro-intestinal system, not as a single long, homogeneous organ with a single function, varying merely in its progress and stages, but rather as a chain of many distinct organs linked to each other, each organ in succession being the part in which some special process takes place, and to regard the remedies of the great cathartic class, not as all of substantially the same effect, but as each endowed with some individual virtue or combination of virtues, and fitted to accomplish some special purpose, and instead of telling his patient to "take a purgative," to prescribe definitely the particular remedy, time, dose and mode of administration

It may be well, however, to append a few practical facts, rules and reports illustrative of the importance of what it has been attempted to inculcate

1 By excessive or prolonged use of certain cathartics, the gastro intestinal system may have its susceptibility to their action so increased or diminished as to forbid their use

2 Different cathartics, for various reasons, act differently on the different portions of the gastro intestinal system, and should be prescribed in accordance with this fact

3 Certain cathartics are specially repugnant or otherwise unsuited to certain persons, and should not be administered to such

4 In case of cathartics, as of other remedies, overaction is apt to be followed by torpor the special irritability of the part affected becoming exhausted and thus acquiring immunity toward the special remedy used, this immunity being of longer, shorter or even permanent duration

5 Mercurial cathartics are regarded as antisyphilitic, germicidal and disinfectant, as regulating the flow of bile, increasing this when deficient, moderating it when excessive, restoring it when suppressed and correcting it when morbid They are specially useful in warm, moist climates and in acute malarial infection, less so in chronic malarial cachexia, in tropic and sub-tropic dysenteries, in sclerosis of the liver and in obstruction of the common bile duct This great variety and seeming contrariety in their action may be due in part to the doses, combinations and modes of administration used or to some existing condition of the patient

6 Drastic or irritating cathartics should be avoided in cases in which there is already irritation of the stomach or bowels, or a tendency thereto

7 In obstruction, in spasm or in great pain in the bowels, the less irritating and most surely acting cathartics, such as calomel or castor oil or the purgative salins, should be selected and combined with opium, hyoscyamus or other efficient analgesics

8 In numberless conditions of disease the purgative waters of the great fountains of health—too numerous here to mention—wisely, beneficently and widely distributed over the earth, or the pure artificial purgative salts, whether as cholagogues, hydragogues, deobstruents or alteratives, are more safe, sure, prompt, pleasant and efficient than other cathartics Such are effervescing magnesium citrate in the obstinate nausea and vomiting of bilious and other forms of malarial fever, sodium hyposulphite in hemato-globinuric fever, magnesic sulphate or sodic sulphate in the dysenteries of the warm climates, in dropsies, etc

Case 1 —V M , male, about 17 years old Sick of bilious fever, nausea distressing , vomiting almost constant restlessness extreme , thirst insatiable , fear of dissolution pitiful, and thought of delayed relief worse than the fear of death

Treatment Effervesing citrate of magnesia, improvised by stirring two teaspoonfuls of powdered magnesium carbonate in two ounces of water in one glass and adding to one half ounce of water in another glass the juice prepared from a fresh lemon, then suddenly adding to the suspended magnesia the lemon water, rapidly stirring, and applying hastily to the eager mouth of the patient At the same time a solution of soap in a half gallon of warm water was being made ready for lavement of the rectum and lower colon and was thoroughly used as soon as practicable This line of treatment, pursued as required, and supplemented by sinapisms or ice to the epigastrium, forehead and spine, speedily quieted the nausea, vomiting and restlessness, secured thorough cleansing of the alimentary canal and made ready the patient for the reception of quinin sulphate, 4 grains, at four hour intervals—all that was further needed in the remedial treatment of the case Sometimes morphin or other anodyne is an invaluable adjunct in the treatment of such a case

In Dallas, Wilcox and some of the other counties of Middle and Southern Alabama, visitations of pernicious dysentery occurred for several years—appearing and disappearing about the same time of year Most of the visitations occurred in June, when the days were hot and the nights cool So great was the fatality that a panic would seize a community whenever the disease would break out and this happened here and there almost annually from 1848 to 1858 The treatment was calomel and opium by mouth, and solution of silver nitrate by rectal injection With rare exceptions the termination was death About 1859, what is now known as the "saline treatment," was generally introduced This consisted in first giving in solution magnesium sulphate or sodium sulphate, with the addition of sufficient tinct opii or tint opii camphorata to lessen the atrocious tormina and tenesmus, until copious, soft, semifluid "actions from above" took the place of the scanty daubs of bloody mucus, that are so strikingly characteristic of dysentery Great good generally resulted from adding to the above treatment pellets of ⅛ grain of extract of belladonna every four hours, to allay the great irritation about the anus and to relax its sphincters In a few instances 30 grain doses of powdered ipecac, with one to two grains of powdered opium to each 30 grains of ipecac were given in pills at intervals of two to four hours as a substitute for the saline treatment Since the adoption of the saline treatment in the localities above mentioned, dysentery is seen mostly in sporadic cases, has a small death-rate and has ceased to excite any great popular dread

Case 2 —L W J , practicing physician, age about 40 years, a constant but not very excessive alcoholic drinker, became subject to spells of pain in the region of the gall bladder, for which he resorted to the use of blue mass Regularly in a day—less or more—after taking blue pills his skin and conjunctivæ would become deeply jaundiced, his pain increased and his alvine discharges were paler and more adhesive This succession of symptoms became so frequent and regular that he was advised to abstain from mercury, on the theory that he was suffering from biliary obstruction, and that the mercury, without relieving the obstruction, was increasing the secretion of bile and thus poisoning and staining his blood and tissues He was also advised to resort to a saline treatment, by using early each morning before breakfasting teaspoonful doses of magnesium sulphate, sodium sulphate, magnesium citrate, artificial Carlsbad, or some other purgative saline In a short while he was much relieved of his troublesome spells, and remained so until he passed from observation

Case 3 —E P , a little boy of about 5 years, who had been from tender babyhood, scratching and crying, day and night, with itch, was brought to me by his mother—one of the neatest and best of women and of housekeepers—for treatment Under the prescription given, the patient improved considerably but now and then, for months, I would be sent for to see the case At length, the dear woman sent for me, and meeting me at the door, with streams of tears flowing down her soft cheeks, said 'Doctor, I want you either to *cure Edgar or kill him*'" "Oh' madam, you don't mean what you say" "Yes, I do," she replied , 'I would rather see him dead and in his grave than to have him suffer longer as he does" In deep sympathy for the parent and the patient, and in deeper humiliation and discouragement at the utter failure of all the vaunted unguents, lotions, antiparasitics and [disinfectants that had been applied to skin, to clothing and to bedding, I sat pensively down and wrote the following

℞ Sulphur flores	℥i	31	103
Potass bitart	℥ii	62	206
Molasses	fl ℥iii	93	309

Mix and put in wide mouth bottle

Sig —Shake or stir well before using, and give one teaspoonful morning, noon and night, or sufficiently often to keep the bowels regularly loose

In due course of time the case was satisfactorily cured, and the grateful mother so valued the prescription, that to the day of her death, she would furnish a copy of it to such of her acquaintances as suffered from cutaneous eruptions

This report illustrates how remedies acting through the gastro-intestinal contents, pervade the whole body, pass through the skin and saturate and disinfect the very clothing of the patient

The parasitic worms, such as tape-worms, lumbricoids and ascarides, have their habitat, not in the human body itself, but in the contents of the gastro intestinal system, and such vermicides as destroy them are generally injurious, and many of them, highly dangerous to the patient They, therefore, require to be combined with cathartics, which, *by preventing absorption and increasing peristalsis*, hurry on out of the alimentary canal the deleterious anthelmintic substances, the disabled or destroyed worms, and the other morbid and morbific contents of the canal In this way, oil of turpentine and santonin, not only do better service by being all directly applied to the worms, but being kept from being absorbed and out of the blood, do not produce painful strangury, dangerous irritation of the urinary organs, suppression of urine and fatal nervous intoxication

This report is made from no particular case, but fairly represents many that actually occur, and aptly illustrates the great therapeutic importance of the rational adaptation of cathartic remedies to the physiologic functions of the gastro intestinal system

---

ACETANILID ITS USE AS A PREVENTIVE MEASURE IN PREMATURE EXPULSION OF THE OVUM

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY STEPHEN HARNSBERGER, M D

CATLETT VA

Squibb tells us that antifebrin and acetanilid are identical This latter drug, under the title of antifebrin, was discovered by Gerhardt in 1845, but it was left to Cahn and Hepp in 1886 to bring it before the medical profession as a remedial agent Acetanilid is a neutral chemic body, produced by the addition of glacial acetic acid in excess to anilin It should be a white crystalline powder, slightly soluble in hot water, sparingly so in cold water, and quite easily dissolved in alcohol, strong wine or ether To detect acetanilid in the urine the latter is shaken with chloroform, and the residue left on evaporation is heated with mercurious nitrate, when an intense green color develops

From the published clinical reports on the subject, it is plain that its clinical application has been confined principally to its use as an antipyretic, and to a less extent, to its sedative action in various nervous disorders and for the relief of pain, but so far as I am informed, Dr J H Wolfe, of Elkton, Va , and myself are the first to find acetanilid a serviceable remedy in threatened premature expulsion of the ovum During the past few years I have used this drug in varying conditions of advantages and disadvantages, in a considerable number of cases, and with decidedly encouraging results At no time have I witnessed unpleasant symptoms, and from its favorable action heretofore I am naturally led to believe it to be absolutely safe, and injurious only when administered without regard to reason or prudence

Formerly I had resorted to viburnum prunifolium, alone or combined with potassium bromid, to meet the pelvic symptoms, and to opium, in one of its forms, for its general quieting effect upon the system But the success of any treatment depends upon the power which the remedies employed exercise over the expulsive efforts of the uterus Some of the preventive measures used formerly, though they very often restored the disturbed function, at other times excited the uterine action by indirect stimulation, and thus defeated the final object. Opium, which was of old considered our sheet anchor in assisting to arrest uterine contractions, in its ultimate results, gives unquestionable instances of not being a trustworthy remedy. It must be noticed that its use too often produces a marked aberration of the functions of the stomach and bowels, and sometimes of the kidneys as well, secondarily at least, exciting the uterine contractions to uncontrollable effort.

Of course in administering acetanilid, as with many other drugs, it might be well for those not accustomed to prescribing it, to consider individual susceptibility and begin with small amounts, 5 to 7½ grains—0.32 to 0.50 grams. But even where the dose has been large, 10 to 15 grains—0.65 to 1 gram—and repeated at short intervals (one to two hours), I have observed no objectionable symptoms, certainly no alarming ones. It seems to possess a special relevance in such cases. Though I have frequently seen it pushed almost to the border-line of cyanosis, I am clearly of the opinion that one of the most striking advantages is the absence of any real unpleasant or dangerous effects. I have never had it produce nausea nor vomiting, collapse nor cardiac depression, in fact, I have seen it act seemingly as a cardiac stimulant in weak heart and as a systemic tonic in protracted nervous insomnia, neither cutaneous eruption nor ringing in the ears. The cyanosis of the lips and cheeks, which sometimes appears, is a symptom of no consequence. I have witnessed no marked action upon the secretion of the kidneys, occasionally an increased flow of urine and this only when the drug manifested a bracing influence upon the heart and pulse. Neither have I observed any evidence of its cumulative action. It does infrequently produce a rather profuse perspiration, but this in no wise interferes with the successful progress of the case, for, contrary to the belief of Dulácska, and perhaps of others, that the drug may, through the powerful action on the vascular system, induce dangerous hemorrhages, the close observer must admit that copious sweats cure hemorrhages. This has been determined too often to be laid down as a mere coincidence.

It is not in keeping with the title of this paper to enter fully into the causation of interrupted pregnancies, but to better illustrate the action of the preventive measure I advocate, I think it may serve a good purpose to make a brief suggestion in this connection. I am inclined to believe that when more reliable statistics shall have covered two or more decades a notable increase in the number of interrupted pregnancies will become apparent. From the result derived from a careful study of the circumstances surrounding such cases, I am also of the opinion that the disorder is not due to a great extent to single causes, but to a combination of several. And, in considering the causes, though it may be in conflict with authorities on the subject, nevertheless, I am constrained to believe that the great underlying cause is an inherited or acquired instability—a systemic and nervous depreciation brought on by the early operation of overstrained and other sinister influences incident to modern times and modern modes of living. By directing proper attention to the predisposing first cause, the tendency to abortions and premature labors can be notably limited. This plan certainly suggests itself to the mind as the only rational way, and at the same time, as we all recognize, it is the way not often left to the physician to follow. The great majority of cases of interrupted pregnancies are sprung upon us suddenly. Then what is to be done but to meet the emergency presented? Certainly we can not go back to undo the ravages remote to conception! The remedies at all serviceable heretofore have required adjuvants which have been frequently attended by evil sequences. In using acetanilid, adjuvants are never or seldom necessary, thus avoiding all reactionary phenomena. This, if for no other reason, should recommend its further trial as advisable in the treatment of threatened premature deliveries.

Whether affections of the endometrium are primary or secondary to mechanic or pathologic changes outside of the uterus, the fact remains that the functional integrity of this membrane is vitiated and that its potency as an essential factor of intrauterine life of the ovum is greatly compromised and natural fetal existence constantly jeopardized. During the course of the first two months and perhaps including the third, even where the symptoms are strongly suggestive, it is no easy matter to forecast the probable pregnancy with any measure of certainty, but with grounds for a fairly correct diagnosis and where nature seems too dilatory or unable to accomplish a *restitutio ad integram*, acetanilid, 5 to 8 grains—0.32 to 0.51 grams—repeated in one, two or four hours, can commonly be relied upon as a helpful procedure. We frequently see women, who are usually regular, pass over a catamenial period. Their suspicions may be aroused, but at the appearance very soon thereafter of the menstrual flux, though it should be accompanied by an increased discharge and more pain, it is looked upon as only a delayed period—they being unaware that one of the clots which has been expelled contained the immature ovum. In just such cases, by the judicious administration of acetanilid a little before and continued a little beyond the usual time at which the monthly flux occurs, the vigor of the uterus seems to be increased and the staying qualities of the ovum strengthened. Again, in those cases of ovarian irritation, where there seems a tendency to the separation of the ovum at what would have been a menstrual period, I think most decided benefit will be found to follow the use of viburnum prunifolium and potassium bromid, with more or less regularity, and of acetanilid at the time of each periodic disturbance. The pain in the back during pregnancy is a nervous susceptibility, and all such patients should be specially careful and on every accession of pain should promptly seek rest and be put upon a few doses of this drug.

Acetanilid has proved of no less benefit in habitual than in simple threatened miscarriages. In a few cases of women who bore histories of habitual loss of the ovum during previous pregnancies, even where the symptoms were alarming—rhythmical uterine contractions, considerable hemorrhage and accompanied with more or less pallor and vomiting—a state of calm was quickly reached under the administration of acetanilid in doses of 10 to 15 grains—0.50 to 1 gram—at intervals of one, two or more hours.

But I will desist from the temptation to refer to every clinical aspect in which acetanilid might be used to advantage, neither will I enter into a discussion of the treatment of the endometritis, nor of the many other pathologic conditions which tend to contribute to interrupted pregnancies—these will occur to the thoughtful physician. It may be well, however, before leaving the subject, to call attention to the fact t [illegible] eir [illegible] symptoms are minimized by administering acetanilid with alcohol, strong wine or ether

I was requested to prepare a paper for this meeting of your association and have presented this one, in order, if possible, to have acetanilid more widely used and its virtue as a preventive measure in premature expulsion of the ovum more fully appreciated

After I had completed my paper, I received a letter from Dr Wolfe, in which he gave me the following brief notes of three cases

Case 1—Was called in August, 1891, to see Mrs E H W, of Elkton, Va, She had on previous occasions aborted three times and said she was confident such would be the case that time I gave her three powders of acetanilid of 10 grains each—one to be given every hour, if required, until relieved She took one at 4 P M and one at 10 P M, the third she never took, as the first two were sufficient to quiet every symptom Patient was delivered three months thereafter of a fine girl baby

Case 2—Mrs E H H, sent for me Dec 10, 1895 Pains every ten to fifteen minutes and rather severe I at once gave her 10 grains of acetanilid Spent the night No more pains No relapse for three months, when, after washing some house hold goods, sent for me in great haste Found her quite sick Repeated prescription with the same result

Case 3—Mrs Wm D, of Elkton, Va In August, 1895, was called to see patient Suffering very much, labor pains every ten minutes Had had ten abortions in succession and no living children Patient was terribly alarmed Gave her 15 grains of acetanilid every two hours, with complete success She went her full time, only taking some dozen powders during that period

In concluding this letter, Dr Wolfe says "No unfavorable effects and but little sweating I might add that I have used the medicine in many other cases with success"

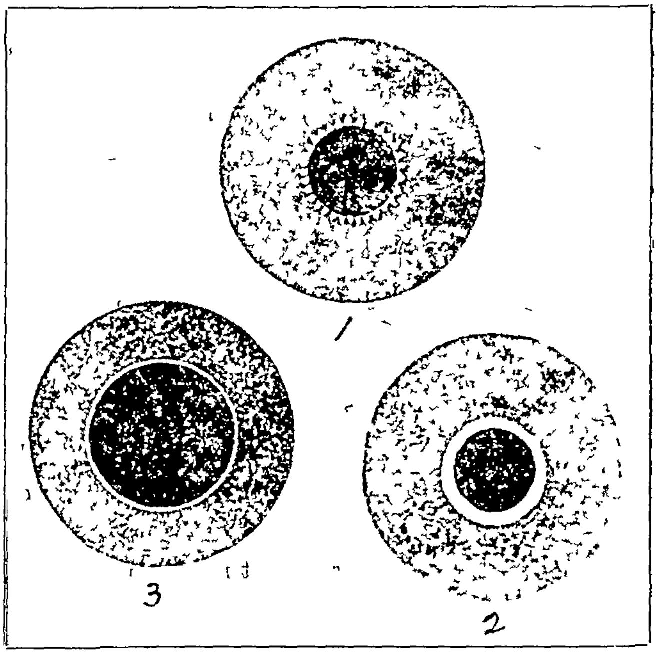
INTESTINAL OBSTRUCTIONS FROM GALL-STONES, WITH REPORT OF A CASE

Presented to the Section on Surgery and Anatomy at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo, June 7-10 1897

BY JOHN PRENTISS LORD, M D
OMAHA NEB

Sunday, March 14, 1898, I was called in consultation to see a man, aged 70 years, who was suffering from acute intestinal obstruction, and suffered from vague gastro-intestinal symptoms for about one year, which had caused him to take medical treatment most of the period, without relief, he had been reduced in general health and strength, although he had maintained a very fair degree of vigor, and had filled his place as clerk uninteruptedly until the previous Thursday, when he was attacked, while at breakfast, with a sudden acute pain in the left side, midway between the umbilicus and the spine of the ileum He left his breakfast uneaten and went to the office where he continued to suffer from pain and nausea, had an evacuation of the bowels and vomited At ten o'clock he saw his physician, Dr Malster, who prescribed and sent him home The pain did not continue to be troublesome, though the vomiting did, and became stercoraceous on Friday Large doses of calomel and salts, together with frequent enemas, had not moved the bowels, and on Sunday it had become apparent that relief must be obtained by other means Vomiting was now frequent and distressing, markedly fecal, and his strength was waning His temperature was 101 and pulse 120 The tympanites was moderate and palpation produced little pain A tumor-like mass was recognizable in the pelvis, below and internal to the sigmoid, and it was thought to be most likely a volvulus, with a loaded loop of bowel producing the tumor, which would account for the suddenness of the attack An operation was recommended as the only recourse promising relief, its dangers, in our aged and enfeebled subject, were fully set forth to the family, who having lost three relatives following surgical operations, during the preceding two years, did not give their immediate consent Lavage of the stomach was thoroughly performed at 1 30 P M, and no vomiting had taken place when he reached the hospital, a distance of two miles, at 5 P M The stomach was again irrigated before the operation, which immediately followed

The bowel containing the obstructing body was readily brought through a two inch median incision, and while surrounded by gauze and the intestinal contents controlled by the fingers of an assistant, through the usual longitudinal incision, a mass of material was removed The mucosa was approximated by Czerny sutures, then a continuous of the serosa, when the line of union was finally fortified by Lembert sutures



Inspection of the gut revealed a considerable deposit of fibrinous lymph upon its surface, which gave the serosa a rather ragged appearance One particular portion of a rough, grayish character, excited my attention, but resembled the other portions so closely that the gut was considered in condition to return

The patient was forty minutes upon the table, suffered little or no shock, had no vomiting after operation, and within a few hours took salts hourly until bowels moved repeatedly The patient's condition was ideal, pulse 85 and temperature 98 Strychnia had been used hypodermatically, since before the operation No food was allowed by the mouth for forty eight hours, but nutrient enemata with alcohol were administered All went well until the third day, when, after a repetition of the saline, evidence of peritonitis manifested itself The following day the wound gave evidence of infection and the retention worm-gut sutures were removed and on the fifth day the wound margins were separated and a thin pus with a distinct fecal odor escaped, after which there was an improvement in both local and general symptoms, which had become quite marked, and from this time convalescence rapidly followed The fecal odor and discharge disappeared with no apparent ill consequences, and the patient has made a complete recovery, he now being better than for more than a year previously

The specimen removed was of about the size and shape of a small hen's egg, but more sharply conical near its lesser extremity, which had the appearance of having sustained loss of its substance by fracture of its apex The body was, for the most part, smooth with the exception of a small irregular elevation on its side, which I now believe to have been the cause of the spot of questionable vitality referred to in the history, and which gave way on the third day, producing the small perforation, which by rare chance terminated most favorably

The lesson from this should be to inspect carefully even apparently smooth solid objects removed from the gut, that their damage to its integrity may be estimated at the time, for the pressure effects from within from even a small elevation upon the surface of the obstructing body, may be very considerable, with but slight evidence upon the serosa, which may be easily overlooked or underestimated

Section of the specimen shows it, without a doubt, to have a gall-stone for a nucleus, the central portion possessing the characteristic radiation of cholesterin crystal, together with the salts from the decomposition of mucous The concretion of material about the nucleus is largely composed of biliary sediment, but in the absence of a complete analysis, I am unable to say whether it is wholly of gall-bladder formation or not A partial analysis shows that it is composed for the most part of biliary sediment and fat The bile contains a considerable proportion of fat, so that this does not preclude the possibility of its being wholly of gall-bladder origin There being an entire absence of a history of gall-stone, colic or jaundice, it is probable that this entire body, or the stone represented by the nucleus, found its way into the bowel by ulceration While the common duct is capable of much distention, yet all will agree that it would not give passage to a stone of the dimensions of this specimen, and certainly not without pain, of which there was no history The statement of the old-time authors that stones as large as hen's eggs are passed by the duct, must not be credited, and we are forced to the conclusion that their belief in their passage through the duct, was by inference, and mistaken for their exit by ulceration, which process can no longer be in doubt, fistulæ, or evidence of their previous existence, having been shown between the gall bladder and duodenum in thirty-three out of fifty one autopsies as well also, were fistulæ found between other organs "Few stones large enough to produce obstruction come from the duct" is among the conclusions arrived at by Roth Literature and weight of evidence, however, would seem to indicate that most of these cases of obstruction from gall stones are developed after the gall stones have remained in the intestine for a considerable time and had their size augmented by the concretion of fecal matter upon their surfaces, which is a possibility in the present instance That single stones of this size do form within the bladder is true, they having been found at autops [illegible] and also having been passed within a few days a[illegible] symptoms of local inflammation, [illegible] ceration [illegible]

obstruction had taken place The bowel may become dilated or sacculated to accommodate the stone, or it may become lodged in Meckels diverticulum, in any of which instances it may become dislodged at any time to form a more or less complete obstruction While *obstructions from gall stones form about* 2½ per cent of the cases of intestinal obstruction, according to Leichtenstern's figures (which are now far from recent) it is probable that with a closer analysis of cases in these later days, when these conditions are much better understood, the percentage will be considerably increased This inference does not appear unwarrantable when we consider the statement of Bevan that cholelithiasis exists in from 8 to 10 per cent of individuals from 30 to 60 years of age, and after 60 years, in the surprising number of 25 per cent of cases examined postmortem Of the cases of intestinal obstruction from gall-stones, 80 per cent are womem This affection is very rarely met with in those under middle age, the great majority being well advanced in years

The manner in which obstruction takes place most frequently is by mechanical obstruction of the intestine from the interrupted passage of a large stone, the stones of less size than the caliber of the intestine are capable, in some cases, of bringing about obstruction, which would seem to be due to an early stimulation and contraction of the circular muscular fibers always found in this as well as in other forms of obstruction Mayo Robson classified three other varieties of obstruction resulting from the effects of the pressure of gall-stones, which he described as the paralytic form, dependent on local peritonitis in the region of the gall-bladder

Volvulus of the small intestine depends either on the violence of the colic, caused by an attack of cholelithiasis, or on the contortions induced by the passage of a large concretion through the small intestine, and obstruction depending on adhesions or on stricture the result of past gall-stone attacks, or of healing fistulæ

From the foregoing, as well as the fact that gall-stones may exist for years without knowledge of their presence, it can not be said to be a reflection upon us if we are unable to make a diagnosis previous to operation, though with a previous history, causing the straws in the stream of events to point toward the gall-bladder, we may be guided to the source Then, too, it is usual that pain is sharp and sudden, though not protracted Vomiting is early and quickly stercoraceous, usually within twenty-four hours, except in chronic or subacute cases, when it may be delayed several days, and distention is not a prominent symptom, for the stone may be, and usually is, above the ileocæcal valve—the lower ileum in half of the cases The nearer the stone to its origin the less the tympanites The cases of greatest abdominal distention, it will be remembered, are where the obstruction is in the rectum, sigmoid, or some part of the large intestine The passage of flatus or feces amounts to no more than a possible evacuation of the bowel below the obstruction, which is most likely to take place during the height of the pain and tenesmus, accompanying the onset of the attack Palpation may reveal the situation of the stone in subjects not too fat The possibilities of s [illegible] n [illegible] s relief by the passage of [illegible] is pro [illegible] m 30 to 50 per cent of [illegible] e [illegible] 80 per cent will die [illegible] ortality from operations hitherto has almost equaled these figures, so that these cases which should be naturally favorable for successful operative relief, present difficulties which leave it an open question when to interfere, and how long to wait before operation is resorted to Delay can not be said to be a safe rule in any form of intestinal obstruction It is my belief that if all cases were operated upon within the first twenty-four hours the mortality would be reduced We must therefore impress the general practitioners with the necessity of earlier reference of these cases to us, as we must in all cases of intestinal obstruction We must lessen the number of last resort operations More of the unfavorable results in operative cases are due to the condition of the patient and the parts involved, than to the fault of the operation

The general practitioner may treat a case upon rational lines, in absence of, or because of unobtainable skilled surgical aid, and present statistics will justify him in his course But under what we may consider favorable surgical circumstances, I believe that fecal vomiting should be the signal for operative interference in gall-stone or any other form of obstruction, where proper and adequate measures have been tried without relief

The measurement of this stone soon after removal was four and one-half by six inches in circumference, and was two and one sixteenth inches in length Marshall of Glasgow reports a case measuring one and three-quarters inches, by three and one-quarter inches in circumference Smith and Fagge report a stone two and one half inches, by four and one half inches in circumferance Conglomerate stones, or those formed by the union of several stones, have made larger bodies than single stones Enteroliths and pure concretions become larger, but these are almost always formed in the large intestine

Lavage of the stomach was referred to in the history, which is a treatment of great value in both the medical and surgical treatment of intestinal obstruction, in my experience And I will here say that it is my usual practice to precede operations for the relief of intestinal obstruction with this procedure and, while it may be the practice of many operators, I do not recall having seen, nor having heard it recommended, it having occurred to me by witnessing patients of mine almost strangle from vomitus in the larynx during anesthesia Indeed, effort at vomiting does not have to take place to cause the stomach contents to overflow in many of these subjects, over-distended with physic and feces The lowered head and a final palpation of the abdomen by the operator are quite sufficient to cause a flood of the fluid to embarrass the anesthetizer and endanger the patient, immediately by suffocation, and remotely from the inspiration of the highly infectious intestinal contents The good results from this practice are always gratifying, not only during anesthesia, but following it There was no vomiting in this case, which enabled the patient to retain salts as soon as consciousness was restored

If the vitality of the gut is not free from suspicion it should not be returned until the proper protection has been afforded against subsequent leakage A few Lembert sutures would have prevented the very dangerous mishap in the case reported Omental grafts are an additional security to the line of union, and should doubtless be more frequently employed

---

THE USE OF ELECTRICITY BY THE GENERAL PRACTITIONER

Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo, June 7-10 1898

BY CALEB BROWN, M D
SAC CITY IOWA

In the successful prosecution of any line of work it is necessary to have good tools to work with, and in no calling is this more important than in the treatment of disease, the relief of suffering and the prolongation of life, which are, or should be, the aim of every physician Were we to examine the armamentaria of the general practitioners of medicine, we would find that where they had electrical apparatus it would, as a rule, be the farthest from up to-date of any appliances they might have The reasons for this are twofold first, the market is flooded with, so far as treatment of disease is concerned, worthless but not always cheap electrical appliances, the fancied merits of these machines being constantly paraded before the medical profession by manufacturers and selling agents, second, physicians are not sufficiently well informed as to what they should or should not buy Were we to ask every general practitioner in this country Do you use electricity in your practice? many of them would answer yes, but should we examine their apparatus we would find in a very large per cent of cases that their electrical outfit consisted of a so-called family or physician's battery, a box containing one or more cells, with a coil attached for the faradic current and possibly an arrangement for the galvanic current, but absolutely no reliable means of regulating the dosage No rheostat, no milliampéremeter, none of the modern appliances

While I do not say that such a machine is of no possible use in the treatment of disease yet I would most emphatically say that it is not what we want if we are going to do good, scientific work As galvanism and faradism are the forms of electricity most used by the general practitioner I will confine my paper to this part of the subject, the electro-cautery being used principally by the specialist, and static electricity, while it is one of the most useful forms of electric energy in the treatment of disease, yet is employed as a rule, only by those who use electricity quite extensively and are, to some extent at least, specialists in electro-therapeutics Let us see then what apparatus is necessary for the proper use of galvanism and faradism First is the cell for generating electric energy Let this be a cell with carbon and zinc immersed in a solution of ammonium chlorid For the galvanic current we will need from five to sixty or even more cells, connect these to a proper switch-board so arranged that any number of cells can be switched into circuit and also any cell or cells can be examined at any time as to their working capacity It is then necessary to have a rheostat for controlling the current and a milliampéremeter for regulating the dose The last named instrument is the most important, for without it no accurate work can be done, as we can only estimate the dose used by the number of cells in the circuit or the sensations of the patient, both of which are very unreliable I will not attempt, for space will not permit, a description of a good faradic apparatus, suffice it to say we must have two to four or six cells like those in our galvanic battery, and a series of coils varying in length and fineness of wire according to the condition we wish to treat, and with an interrupter that can be regulated to give slow or rapid vibrations

A full description of the proper use of the positive and negative poles in galvanism can not be given in this paper but is better learned by a study of individual diseases in text-books on electro-therapeutics While polarity of the faradic current has been denied by some yet there is certainly a difference in effect produced by the application of the separate electrodes We may say as a rule that the most active polarity is the negative and should ordinarily be placed nearest the affected part Or in general faradization the current should be directed with the blood-current

In studying these two forms of electricity—galvanism and faradism—in their physiologic effects and therapeutic uses we must remember that the galvanic current is of large ampérage or volume and small voltage and its action is chemic or electrolytic, while the faradic current is electro-mechanical, having a low ampérage but a very high voltage Having these two thoughts firmly fixed in our minds we have made a start in the right direction in the study of the effects of electric energy on the animal organism

If we also understand the pathology of disease and have proper electric apparatus we are ready to begin the practice of electro-therapeutics, but to carry it out successfully we must understand the subject of electricity as a physical science, we must know our anatomy, physiology and pathology perfectly, we must learn to use it where indicated and dispense with it when it is contraindicated as we would any other means of combating disease I am not of those who think electricity a panacea for every ill or that it should be universally made use of, but when intelligently used it makes our medicinal treatment more effective

First among diseases treated by me in which I have found electricity beneficial I would place goiter I have treated this subject more fully than the limits of this paper will allow in a paper read by me last year at Harrisburg, Pa , before the American Electro-Therapeutic Association In that paper I gave results of treatment in quite a large number of cases of this disease I will not devote space to describe the various forms of goiter further than to say that, aside from a true tumor growth, goiters are hard, soft, vascular or cystic, according to amount of fibrous tissue, fluids or blood-vessels entering into their structure And we may state, in a general way, that the harder and firmer a goiter the less curative effect as to reducing its size will electricity have, yet on the other hand, although but little may be done in reducing the size of a firm goiter by electricity (aside from electropuncture), yet it will relieve to a great extent the nervous symptoms and pain, and even in exophthalmic goiter we may do much to slow the heart, calm the nervous system and improve the general condition of our patient

The proper form of electricity in this disease is galvanism placing one pole on the back of the neck, or behind the angle of the jaw, the other on the tumor a very strong current is not necessary . Reverse the poles, placing first one then the other on the back of the neck or one on each side of the tumor, shifting them often enough that too great irritation of the skin will not result Give medicine if condition of system demands it I have never used electricity in this disease that the case was not benefited both in decrease of size of gland and relief of nervous symptoms Many cases are cured, in some the gland has again enlarged, others have remained cured But when we remember that latent embryonic cells may be stimulated by an enlarging thyroid body and a true tumor result, amenable to surgical treatment alone we see the importance of curing these cases in their early stages, and for this, one of our greatest aids is undoubtedly galvanism

We who do a general practice often have patients come to us who complain of pain in various parts of the body, muscular soreness, lame joints and a general worn-out condition I remember seeing a statement by some medical writer that when you have a patient with a pain you can not account for in bones, joints or muscles to give iodid of potassium, I usually go one step further and use, in conjunction with the iodid or any other proper medication, general faradization, and with happy results

In neuralgia we often have great benefit from the use of electricity If the pain in a nerve is caused by neuritis, electricity is perhaps not our best remedy, but the further we get from the acute inflammatory condition and the nearer to the chronic inflammation or purely functional trouble the better effect we will have from this agent, and in all such cases it is indicated and is very helpful This is markedly so in sciatica In using faradism in this disease use a high tension induction coil with negative pole on sacrum using an electrode four to six inches in diameter, connect a smaller electrode with the positive pole and place over the course of the nerve

To use galvanism in the same disease place a large electrode, five to nine inches in diameter, connected with negative pole over the sacrum, a somewhat smaller one connected with positive pole firmly over one of the most painful points of the nerve, increase the current from zero until a feeling of warmth is produced, hold it so for a few minutes, decrease it gradually and treat each painful point in this way The current will need to range from five to ten, fifteen, twenty or even more milliampéres, according to the effect

The range of diseases in which electricity may be used to advantage by the general practitioner is very wide and new uses will suggest themselves to him as his experience increases Where I have found it most useful is in functional nerve troubles, subacute inflammations, such as chronic rheumatism, in neuralgias, lumbago—and here it is particularly useful—also as a general tonic, and last but not least, in goiter, when used in appropriate cases

In conclusion I would say that when we use electricity let us use it intelligently and with care, let us study it as a physical science, let us study it in its physiologic manifestations on the animal organism, but above all let us study the pathology of the diseased conditions we are to treat Then if we will get good apparatus and use it with as much intelligence as we would give any drug, we will find electricity to be a most potent factor and a strong ally in our battle against disease

But let us not make the mistake of considering electricity a cure-all, but ascribe to it its proper place, believing that a force that can propel cars, run the heaviest machinery, light a city or enable us to talk across miles of space, or break up molecules into their ultimate atoms, must have some effect, when properly used, upon the metabolism of the human organism

CONSERVATIVE TREATMENT OF INTESTINAL OCCLUSION BY INTERNAL ELECTRICITY

BY R P JOHNSON, M D
OAK PARK, ILL

In reviewing the different means of relief recommended and practised by American medical men for the cure of intestinal obstruction, the investigator is led to believe that what is regarded in some of the European medical centers as safe, successful, not interfering with the employment of the more radical procedure — laparotomy —is entirely ignored, or in fact, not even considered here From a fair amount of investigation of the subject I am convinced that the American practitioner is neglecting to employ therapeutic means that have been satisfactory for years to many of the most eminent men of Europe

The physician who is called to see a patient, whose most prominent symptom is one of non-movement of the bowels, may have a very obscure but serious case to contend with Cathartics and enemas have been ineffectual, so it is a case of obstruction What is to be done? A surgical operation may be the proper thing If there is hernia, a stricture or lodgment of foreign body, a knot or a loop in any way strangulated, it will be the proper thing and should be done at once But how are you to determine? Some say that a laparotomy must be performed, but the operation is too serious as a means of mere diagnosis If the condition is the result of an intestinal concretion, an impaction of fecal matter, a paralysis, producing some dilation of the walls of the bowel and many other conditions that go to make up the pathology in these cases, laparotomy would be a failure The last enumerated cases are not to be relieved by surgery We have excellent authority for saying safer and better means are at hand

I here quote from a recent article from the pen of Dr J Larat of Paris, France Dr Larat's experience and standing in the profession are sufficient guarantee Dr Larat says, in speaking of the good results of the electric injection as used in the hospitals of Paris "In cases of intestinal obstruction let us see what the therapeutic results are Dr Boudet of Paris, in statistics taken from 50 cases, reports the successful operation of 70 per cent" In speaking of himself, he says "I have now applied the injections in 250 cases I have obtained a clearing of the intestines in 101 cases Thus my successes are less than those given by Dr Boudet However, they still remain satisfactory All my cases have been seen by my colleagues, who called me in to assist their patients, and at least one half of them are doctors of the hospitals Thus my statistics have been well tried, and it would be easy for me to secure the testimony of my colleagues and masters When called to see a case, and after having tried a purgative and an enema without any result, do not insist any longer but immediately administer the galvanic injection In twenty four hours it will be recognized successful, or not In cases of failure, propose a surgical operation to the patient"

If the above statements are trustworthy, they leave no doubt as to the positively curative effects of electric injections on cases of obstinate constipation, where there is great torpor of the nerves supplying the muscular coat of the bowels The condition of the semi-paralysis is fully proven by the great want of response to cathartics and also food that is inclined to keep the bowels in a soluble condition Nothing has so decided an effect on nerves partly paralyzed from a functional condition as electricity, and especially of the form of galvanism, where the muscular fibers are non striated, as in the bowels and other hollow organs Dr Larat's conclusions are worthy the consideration of every physician and surgeon In the advice which he gives in the management of these cases he certainly shows a fairness and professional dignity worthy of the eminent physician he is He in no way tries to belittle the grand results obtained by surgery To further substantiate what may be regarded as an unwarranted and unjust statement that the American practitioner is neglecting to employ therapeutic means that have been satisfactory for years to many of the most eminent men of Europe, I here append a list of sixteen printed medical documents that can be found in one library of Chicago on the obstruction of the bowels cured by electric injections Of this list of sixteen medical articles, which are generally in the form of reports of different cases, only three are from American writers For the collection of the above articles I am greatly indebted to Dr Mangus Moreneus, who has charge of the department referring to electricity, in the Newberry Library Dr Larat of Paris, France, gives a list of printed reports on this subject by twenty-four different authors, not one of whom is American Beside the forty articles above referred to, I have the names of title and authors of thirty other printed articles on intestinal obstruction and constipation, treated successfully by internal electricity, not one of which are from American writers They would make my article too tedious to give them all here

It would appear that surgical interference is sometimes resorted to rather rashly I here quote from the pen of Dr Mathews, in his most excellent work on "Diseases of the Rectum" Dr Mathews is president of the American Medical Association, and is recognized authority In speaking of the obstruction by fecal matter, he says such accumulation has ended in the death of the patient Obstruction caused by fecal matter in the cecum has been confounded, time and again, with appendicitis, and operations have been done, looking to the removal of the appendix, which were unwarrantable, and right here begins the much discussed subject — whether these cases belong to the surgeon or the physician Dr John Ashhurst, editor of the International Encyclopedia of Surgery, in a recent article on "Intestinal Obstruction," says "I very much fear that at the present day, the hasty resort to operative measures, encouraged by the much vaunted modern triumphs of abdominal surgery, is responsible for the loss of a good many lives which might, perhaps, be saved by more rational if less brilliant treatment"

From the statement I have quoted from Larat, it would appear to the unbiased mind that where the pathology is obscure, therapeutics in the form of internal electricity should be tried first If this treatment will relieve the cases where surgery is not suitable—which are fully 50 per cent of the whole—and in no way preclude the knife in surgical cases, certainly the mortality can be greatly reduced The statistics of cures by surgery would be very much better if cases not indicating surgical assistance were treated as here advised No fair-minded physician or surgeon is so enthusiastic in his own specialty as to desire professional work where his efforts will be unsuccessful I think you will find no other disease in which the per cent of cures are so evenly balanced between the efforts of therapeutics as here described and surgery A monopoly in either department of the science and art of medicine and surgery in these cases can not fail to greatly increase the rate of mortality, and when you consider that the use of electricity need not require more than twenty four hours to give it a fair trial, it can not be objected to

The electric enemas not only assist in removing the obstruction by inducing a normal peristaltic action, but impart tone to the vasomotor nerves which supply the non striated muscular fibers forming the muscular layer of the intestines

It is a well established principle in electrotherapeutics that the active pole of the battery should be as near the tissue to be treated as possible What I mean by the active pole is the one in nearest proximity to the diseased tissue Convinced that strict observance of this principle was important in order to have success, and having some cases of obstinate constipation to treat, about one year ago I had constructed a special rectal tube inclosing an electrode The electrode is so constructed that it supports the caliber of the tube, thereby preventing its kinking or doubling, which enables the operator to pass it into and beyond the sigmoid flexure In this way the colon can be thoroughly flushed, and by connecting the cord-tip of the battery with the binding-post of the positive electrode, and the sponge of the negative electrode over the abdomen, or some other part of the body one can administer a thorough and real electric bath to the mucous membrane of the colon Peristaltic action is generally set up in from one to five minutes Certainly no other therapeutic remedy is half so potent, with no danger nor pain

As to the amount or intensity of current to be used If the battery is not supplied with a milliampéremeter or galvanometer, it will be safe to rely on the sensibility of the patient Commence at zero with either a galvanic or faradic current and slowly advance to the degree of considerable warmth with galvanic current If you use the faradic current a greater degree of sensation from the current will be required After the current is continued for a few minutes, turn back to zero and again slowly increase to the former intensity If at this point of procedure the patient expresses a desire to go to stool, at once discontinue the treatment If the desired results are not obtained repeat the treatment in from three to six hours

As to the kind of electricity to be used, Dr Larat of Paris, whom I have freely quoted in this article, says the galvanic current has the most decided effect on non-restricted muscular fibers, such as compose the muscular wall in the bowels, bladder and other hollow organs, nevertheless, in the list of printed articles and authors I have here mentioned, the faradic current has been the most generally used As to the fluid to be injected A 1 or 2 per cent salt solution is more efficient than mere warm water, on account of more thoroughly dissolving the mucus covering the membrane, and also, of about doubling the strength of current of electricity imparted to the mucous membrane In speaking of my own success with this form
of treatment for the past year I will only say
pectations have been more than realized The
ments that I have been using and

most satisfactory to several specialists can be found at the Hydro-Electric Instrument Co, Chicago

If in the large list of authors I have referred to, only three are of our own country, does it not indicate that we are a little slow to investigate this very important matter? Can it be that omissions like this have anything to do with sending so many to European centers to complete their medical education? I do not assert that it is so, but suggest it for the reader's consideration I would not refer to this so much at length if the remark, in substance, that the virtues of internal electricity in the treatment of intestinal obstruction and constipation have not as yet been fully demonstrated, had not been made to me many times by physicians in the last year

Some who read this article may suppose it is from the pen of an electrotherapeutic enthusiast and one not having had experience in surgery To disabuse the minds of such, I will say that when quite young I was an assistant-surgeon in one of the Ohio regiments in the War of the Rebellion, since which time I have had many years of experience in railroad and general surgical work and am by no means faint-hearted I could not if I would, and would not if I could, cast a shadow over the grand achievements of American surgeons In a humble way I am one among the many But in the van for professional preferment, for which we are all striving, let us not lose sight of the fact that he stands nearest head who does the greatest good to the afflicted, even though it be with the simplest means

FORMATIVE NUTRITION

Presented to the Section on Diseases of Children, at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY H W SCAIFE, M D
CHICAGO ILL

As defined by Webster, nutrition is an "act or process of promoting the growth, or repairing the waste, of animal bodies," from which it appears there are two divisions of nutrition The first is a "*process of promoting the growth*' And it is to a
c leration of that paper is devoted, and
lle trition'
en for counsel,"
n the face of

disease and death which formative nutrition gives to the young It is then at its best, its capacity for repairing the waste has attained its maximum, and then the frame ceases to be augmented

On an inquiry into the process of forming and building animal tissue, the first point of importance is to find the seat of nutrition, which is easily determined by reducing tissue to its simplest factor, that we find to be the cell, and the cell, according to classic plan, consists of envelope, protoplasm and nucleus Each of these has its part to perform That of the nucleus is unimportant and can be dispensed with in some instances, the protoplasm seeks out and chooses the food, the nucleus, devoid of mobility, presides over the building up process The nucleus will replace any part of the cell that has been removed by the knife, and hence we have only to infer that the process of formation is effected by the same agent as that of reformation, and the conclusion is the seat of formative nutrition is the cell nucleus Binet says "The nucleus is the essential factor of the plasmic vitality," and "if, to use an old comparison of Aristotle, we compare the protoplasm to the clay, we must compare the nucleus to the potter that has fashioned it" From which simile an inference is to be drawn which may affect the question as to which parent the child should most resemble The mother supplies most of the material, the vitelline protoplasm, but this exerts no formative influence, this is food, while the formative impetus is given by the nucleus By the rapid segmentation of the cell, in which the nucleus always divides first, the being is increased in size and takes on form, it augments in substance, cell arranging itself with the other cells, and appropriating for each organ its separate function

Another phrase, "As the twig is bent, so the tree inclines," indicates the importance of getting a good start It emphasizes the responsibility of the physician whose duty is as the husbandman's, in whose care so many young trees are placed for cultivation To his judgment the future welfare of many infants is committed He is the adviser of the young parents as regards tending and feeding their infant offspring, and often is forced on him a dreamy speculation as to the method nature employs to make a normal figure or one abnormal, a plain man, a vigorous giant or a puny dwarf On either hand that which is abnormal may be considered the cause of a disease, depending on the function of some obscure organ, as the pineal gland But apart from causes, he knows nutrition is the chief thing for him to understand, to enable him to advise wisely what food to give to form muscle, bone, nerve or brain, according as to what is needed when his advice is asked He thus is compelled to think at times of the deep secret nature has hidden in formation of animal figures

In the first place we observe that this process is rhythmic, as all other things in nature, and that we have not to expect the same results at different epochs, but varied success At one time one kind of food is needed, at another, another kind, and as the seasons and circumstances vary, the food should vary accordingly The ovum has its time to mature, the embryo its time to quicken, the fetus its time to be born So the infant has its time to grow chubby and its time to grow lank As a plant, the child will increase in height between April and August, and in weight between August and December To learn more of these variations, and to explain cause of the changes as we do the phases of the moon, or the ebb and flow of tide, is desirable, to take them into account in studying what to do for individual cases is necessary But as yet, food is the only thing we can understand and control to any great extent, and is therefore the all-important subject to consider in regard to nutrition It controls the destiny of every child born, and determines whether they shall be great or small It is said fishes in a small fish-pond are small in size, but if you enlarge the size of the pond the fishes grow larger, which shows that size is often determined by the quantity and quality of food which is available The change of food from the solid substance to the nutrient fluids, and the internal secretions by which this change is accomplished, are fairly well understood Its reduction to chyme and chyle, its osmosis and final arrival and reception into the blood-vessels is told us in every physiology And now the secretions of the ductless glands and their effect on nutrition is being studied by specialists, and new and interesting discoveries are being made They are found to be necessary to health, their several defects have been found to bear certain relations to diseases of special malnutrition, as, for instance, the relation of defect in the pineal gland to that disease of acromegaly But when we arrive at the point where assimilation occurs, when we come to the functional physiology of the cell, our task becomes difficult and largely partakes of the character of guesses The nutrient fluid of the blood passes through the cell If the cell be one of the salivary glands it comes out ptyalin, if it be one of the peptic glands, pepsin If it be some other cell it may come out as a white or red corpuscle of the blood, and be ready for building up the organism by growth, or for repairing the waste when growth has ceased

The process beginning with the act of eating, and going on up to assimilation, is called digestion, and as I have said, is fairly well understood That beginning with assimilation and ending in excretion is called metabolism It embraces, 1, pabulum, 2, a substance actually in contact with life, and 3, excretion This process is again divided into two parts the first half, in which the cell substance, the cytoplasm, is coming in contact with the living principle and is being builded into living substance, is called anabolism, and the second part, belonging to excretion, the breaking-down process, is called katabolism That is the process evolving animal heat Now, when anabolism is greater than katabolism, we have growth, which takes place in two ways, either by multiplication of cells or by individual enlargement Minot has pointed out the difference between a growing and a matured cell He says that "the proportion of cyto plasm to the nucleus" was less in the latter So the cell arrives at maturity when the matter of the cell and its nucleus bear a certain proportion to each other in size And if the time taken for this be constant, the duration of its existence can be deduced by aid of another proposition

The normal duration of life of animals is, some think, five times the time it takes that animal to mature Observation, however, seems to have shown that some animals of the fish species grow as long as they live Geology shows us animals in earliest ages of enormous dimensions Mythology tells us of serpents that would measure one hundred feet We read of the remarkable ages of the patriarchs, and sometimes also of their enormous size In the plant kingdom we still meet with remarkable longevity The common bracken fern never dies of old age The oak tree may live a thousand years Nature is in no hurry to separate life from organism, but leaves it in its environment till a purpose in evolution has been accomplished for it It begins with a growing point in a unit or cell, the arca germinativa or nucleus This commences to grow From it radiating lines are sent out through the cryptoplast by which every part of the cell is reached This in animal life is regarded as the basis of the nervous system It grows till we get a spinal system, a sympathetic system and a brain, each exerting continuously, severally and combined, an influence on nutrition as at their inception "It may be," says Halliburton, "that all nerves have power of transmitting trophic impulses" He means the nerves are the builders of the body, and what is behind them is food

Professor Holt says "In building up the cell the proteids are first in importance, the carbohydrates second, and the fats the third" And under the head of the mineral salts he says "they are of greater importance in infancy than in later life, because we find that they are stored up in the system at that time more than later on" Is that all? In Parkes' Hygiene we learn something more on mineral salts They are food for vegetables The lowest forms of life will not grow without earthy phosphates "The growth of wheat is more quickly checked," he says, "by the absence of phosphoric acid than any other constituent from the soil" But the mineral salts which are necessary for plants are changed when incorporated in plant substance for food for animals It was said so when organic chemistry began to be studied, and though chemistry has had many triumphs, as for instance the manufacture of uric acid, it is almost certain that minerals that have not been prepared for our use by being incorporated in vegetable organisms are not food Therefore it is a misnomer to call those that have been prepared as proper foods mineral salts, or at least it is misleading, unless exception is made of the chlorid of sodium, of which Foster, p 840, says "200 grams a day are essential for the discharge of metabolic function" In which instance we may regard it as a necessary environment for the living principle, not a pabulum It assists in the elimination of excreta which the life principle is constantly throwing back into the blood, and which, by the help of sodium chlorid, can be excreted from venous blood through skin, kidneys and lungs The other salts, and chiefly those of the phosphates and acetates, are given to us for food through the vegetable kingdom, and their absence produces the highest form of acute malnutrition, called scurvy It is well we emphasize the importance of these salts to the young, but not well to emphasize the adjective mineral Neither minerals nor mineral waters can be recommended for infants or for the young The salts they need are those furnished by vegetables, and in point of importance should stand first on the list as tissue-builders in formative nutrition Protoplasm is the material used in construction of the body, the carbon, the nitrogen and the hydrogen are the brick, the wood and iron of protoplasm Oxygen is the workman's tool, the hammer and saw, while the builder, the force regulator, is phosphorus

In plant elevation the process of nutrit
thetic, accomplished by sunlight through
of chlorophyl By its action the rays is stored up and becomes potential Nutrition in the animal requires a further "very remarkable psychologic process," and constitutes a method by which this potential energy becomes active and is used up or expended, so the animal receives its energy as it should do its substance, from the plant directly, or indirectly through the body of some other animal Sunlight may be absent from its growth, though it can not be absent from plant life The glowworm will give up the light absorbed by day in the darkest night, so may sunlight be faintly replaced in animal growth, when building in darkness, by the phosphorescent element derived from plants

But with writers on biology it is usual to acknowledge that we do not know how a living substance builds itself up And that means we do not know the process of formative nutrition A writer on micro-organisms says that "simple cellular psychology is a conception of the mind, rather than a study based on observed facts" Now we have viewed a few facts on which we may try to base our conception of cellular psychology The fact of long-continued life and gigantic forms in early eocene ages gives us an association of small minds in big bodies And in giants we have now we do not see higher development of mind attending larger bodies We expect to find it otherwise, as if the body can be developed at the expense of impoverishing the brain Consequently the alternative may be true, that the body can be stunted by abnormal development of brain and nervous system If, then, formative nutrition be arrested, it may be either debility arising on the one hand from improper food, or on the other hand from an insufficient supply Or it may result from too much mental exercise, too many studies, or too many cares of life If it be the former, improper or insufficient food, the result is anemia, marasmus, scorbutus or rickets, or if it be the latter, we have precocity Suppose we take it to be the former condition, then we must remedy conditions

In house plants we sometimes see luxuriant growth and yet no flowers The anxious owner knows not what to do with her plants Accidentally she sees a "plant-food" advertised, buys it and gives it to the soil—marvelous change! The plant ceases growing and begins blooming That plant-food was perhaps nitrogen in a form that could be assimilated by the plant Hence the sudden change Many children are like house plants, in need of a particular change of food They need phosphorus Their cartilages must be changed to bone, the phosphates of sodium into the phosphates of calcium, and the phosphates in the food are needed to effect this The anxious parent inquires, Why is it that my child does not grow? He fills it with medicines that have the best reputation for remedying these troubles, and still no change will come—no improvements But pure air and poor living would get it, if by poor living we mean brown bread, skimmed milk peas, cabbage, pork and beans, oatmeal, and less white bread and butter, less tea and coffee, less medicine and fewer school studies

Now, as to the expression of opinion touching the importance of phosphorus in formative nutrition, we find it supported in the standard works of physiology Of the ide od for infants, M Foster
p 61 milk consist of phos-
process of curdling
tes appear to be

absent And, beside the phosphorus in the actual form of phosphates, milk contains further considerable quantity of phosphorus in the proteids and in nuclein " To the child who is not fed on milk, with so many factors necessary in nutrient-food, one may fail to be supplied by its artificial product Hence, we may find that a diet prescribed with scientific skill, will fail sometimes, when success attends the other regulation of diet by an untutored mind One mother says "my baby did well on Eagle Brand," another, "that brand was no good for mine" One prefers Horlick's malted milk, another, Mellins', some try them all without achieving any success Why? Because the ingredient phosphorus is not given in sufficient quantity, while in the instances where prepared food succeeded, it may have been supplied from an independent source, as for instance, by the addition of good cow's milk For M Foster says, p 630, "from a biological point of view, the phosphorus is no less important than carbon or nitrogen "

Manufacturers do not put up a food for the market devoid of carbon or nitrogen, these are blended in exact proportions, but no account is taken of the salts One says, when cow's milk is properly diluted the salts may be dismissed from separate consideration, and yet the same will acknowledge that an infant may thrive on one woman's milk and suffer immediately from indigestion if put on another woman "It has sometimes been necessary," he says, "to try a dozen " "It is possible," he says, "to vary the percentage of fat, sugar and proteids in milk to almost any degree desired, and to do this with very great accuracy ' "At present," the same author says, "a separate modification of inorganic salts is not attempted " Though this style of preparing food may be of great value, when other important things are not overlooked, it is nothing to be relied on when the salts are regarded as being impossible to regulate It only teaches the parents and physicians indolent reliance on manufactured articles in false security, instead of studying and practising the proper cooking of natural foods And we need not believe that accuracy of proportion of carbon and nitrogen a positive necessity, for what was the anus given us if not for the elimination of unproportioned elements? Better leave it with a burden of work to do, rather than omit a small article of diet that is necessary for the proper performance of assimilation

The numerous prepared foods for infants may all of them be useful for a change, though they may not contain the salts in the proper kind and quantities, for the carbon and nitrogen which they do contain But life and health can not long be supported by them exclusively, and when the child is healthy we never think of using them

In general, it is best in directing the diet of children to discard long courses of medicine, or drugs and prepared foods, and to try and select their diet from such foods and condiments as are generally found on the table, for we are then liable to get all those elements of food that constitute the body Then we shall stand a good chance of succeeding in improving malnutrition of any description, and of proving the benefit of our profession to a needing part of the community

Physicians' Book keeping —The courts in Paris recently decided a case on the principle that a physician's books were sufficient evidence of his claim, unless there was manifest exaggeration

---

SOME THOUGHTS ON THE CARE OF INFANTS AND CHILDREN

Presented to the Section on Diseases of Children, at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo , June 7 10 1898

BY J A WORK, M D

ELKHART IND

Of all the young of God's vast creation of animated nature, none are so helpless as the *newborn babe* The young of the lower order of animals can all early help themselves to their furnished food, not so with the human species, thus the demand for especial tender care, and how generously the mothers with natural affections bestow their aid and sympathy to the little weakling Though perfect in its anatomic construction, yet as soon as breath enters the heretofore functionless lungs, the whole animal machinery of many members moves into new activity, and we can now declare, surely, that a new life exists The first care that the infant's helpless nature demands is at the hands of the accoucheur and nurse, the responsibility largely resting on the former The proper start in life, as in every other great undertaking, is an important factor to success

It is fitly asserted, from a moral standpoint, that the beginning of the child's moral culture should precede its birth at least two generations, no less should be required of its physical training Heredity should receive due consideration as to offspring The very tender, pliable brain cells become arranged very early in life, in accord with its environments, habits of system, whether good or bad, become soon fixed and it becomes extremely difficult to change them How deplorable to find a mother ignorant of and not competent to understand the first principles governing the physical interests of her offspring This condition of mother, together with a careless or perchance impractical, inexperienced medical or physical adviser and nurse, presents anything but a flattering future for the helpless little creature of circumstances, however, we will take a more hopeful view and assume that all parties concerned in the well-being of the infant are adequate for the occasion

With a mother ordinarily endowed, physically, morally and mentally, an accoucheur of good judgment, ever ready for emergencies, if any should arise, a nurse capable of obedience (at least) to all the details given her by her superior, the doctor, we are in a proper condition to safely assist the little personage to his new and unexplored realm, suited to his wonderful possibilities However, not a few infants are injured for life (and a miserable life, too) just at the last stage of the labor that gives them an existence Sometimes this commiserable event is unavoidable, I refer first to the effect on the cranial viscera due to the employment of forceps, which injury of the brain the child scarcely, if ever, recovers from, second, the cervical portion of the spinal cord is often injured, or at least sometimes, by severe traction by the head and twisting of the neck, with or without instruments, when the shoulders are difficult of deliverance, this occurring usually after the head is delivered, and can be avoided by the accoucheur hooking his index finger into the axilla of the child, and thus employ traction which does *not* strain or injure the spinal cord

All things being equal, the first care of the infant's body is to cleanse the surface of all extraneous or precipitate substances by the employment of some oleaginous agent, rich in glycerin Fresh aseptic lard is the most efficient for this purpose of any substance I have yet employed After the surface has been thoroughly anointed and the precipitate thus dissolved, then wipe with a soft cloth with as little friction as possible, and by not employing any kind of soap, the normal oil of the skin is preserved, and the above procedure adds to, rather than takes from, the normal condition of the surface, and renders it less liable to chafe

The umbilical cord should be dressed in surgeon's aseptic cotton, and thus treated, as a rule it need not be disturbed, neither will it disturb, until it sloughs

I do not recommend washing the infant's body oftener than once in two or three days, but during the interim of washings, gentle friction of surface of body with a soft cloth or hand, is good treatment In washing, soft water should be employed

Bands around the body should not be too tight, but should be snug enough to support the walls of the abdomen in case of distention Clothing should be of the softest texture, and its conducting or non conducting properties should be according to the conditions of the atmosphere If mothers were taught and impressed with the importance of changing their children's clothing with the change of the atmosphere, I daresay many precious lives might be saved to the home and society, and much grief prevented The child's clothing should be of equal warmth—that is, if possible, the surface temperature of all parts of the body should be the same and so maintained, and it is important to have clothing so constructed as to have equal pressure This latter proposition should be also required of grown-up babies, and upon equal pressure, or, rather no pressure, depends equal circulation and warmth, to a greater or less degree

Face and hands should early be habituated to the atmosphere, not forgetting the self-evident fact that the infant is a new and separate being, and must do its own breathing, and should have a living chance to do it The atmosphere should be of the purest quality, and not from under the bedcovering of the mother Temperature of the nursery should be from 85 to 95 degrees at first, and gradually lowered to 75 degrees however, several days should elapse before reaching the lower temperature Each individual case demands its own peculiar care, and the successful accoucheur must be an efficient nurse, or at least he must be competent to instruct his nurse efficiently, according to the needs of each particular case The nurse is the physician's agent, or orderly, and should be so instructed as to readily know what constitutes a normal anatomic and physiologic babe, so that she may instantly discern any deviation from the standard, thus the need of trained and educated nurses in general obstetric and nursery practice

The first few days of the infant's existence will reveal any anatomic or physiologic defect or weakness, and it is within the province of the nurse to notice any defect which has escaped the casual and hurried scanning of the busy attendant physician and she should report at first opportunity An effort should be made early in the child's life to correct defects, whether they be structural or functional, with a reasonable hope of success in a majority of cases

One of the most irrational procedures in child culture is to neglect the physical while developing the mental, in fact, a proper development of being requires a strict observance of all the immutable laws governing development or evolution It is a sad mistake to withhold any of the vital stimuli from the *feeble*, whether it be of either body or mind Pure outdoor air for the feeble infant or child, even at an expense of warmer clothing than is required for in doors, is a wise investment, and will in time count on the credit side by bringing color to the cheeks and vigor to the priorly lax muscles, especially where the child is properly nourished And I will note right here, that this department of the nursery is attended with more disaster than any other There is a great diversity of toleration of food and powers of digestion and assimilation This being true, it requires greater wisdom than is usually manifested to manage successfully the average child's larder

If mothers can know the first symptoms of indigestion and take warning, know what to do and do it, if their sympathy did not overcome their judgment, much trouble could be averted We must institute training schools for mothers, as we have for nurses, or else compel doctors to take time to instruct the young mothers, with authority to enforce obedience to the instructions The deleterious results arising from the mistakes in the feeding of children are greater than in any other department pertaining to their physical culture All things being equal, the mother's milk is the best suited to properly nourish the infant Too often infants are weaned from their natural food too soon, without a reasonable cause, and substitute foods employed suddenly are dangerous The proper and rational procedure in weaning a child, as a rule, is to wait until we notice an insufficiency of the natural food, and then *gradually* add the artificial, commencing with the smallest possible addition and increasing until we reach a sufficiency The child will usually wean itself As a rule, the Creator has wisely and abundantly provided nourishment for the infant, and substitution is unwarranted and is next to criminal Next to the mother's milk, at our command, is fresh cow milk, if carefully and wisely administered

Some contend that cow's milk should be sterilized If it is not properly collected and contained, it is well to sterilize it, but if milked into sterilized containers and used soon after, there is no more necessity of going through the process of sterilization than there is to sterilize the mother's milk In either case the *fresh milk* is sufficiently sterile, if the source is healthy

DISCUSSION

Dr William C Hollopeter Philadelphia—First I would emphasize the fact that the first cleansing should be done with oil An infant should not have water applied before several days after delivery Several years ago I had occasion to study this question particularly in reference to premature infants I had two patients with deformed pelves, and I have delivered them each of three infants, one at six months and twenty three days The care of that infant consisted simply in keeping it in an equitable temperature with oil and not touching it with water, except about the nates with a cloth wrung out of hot water Such an infant may have its death insured by improper treatment Many infants die in the winter season by gradual cooling of the extremities, especially after being washed with water I had a case two or three years ago in which I am sure the infant died from that sort of exposure, although it was in a well to do family in the country On the second or third day after its birth, at the beginning of the seventh month, it was being nursed by a trained nurse before a warm fire, wrapped up in a great wad of cotton on a cold bleak day The cold draughts of air from the windows and doors going toward the fire, the side of the child from the fire was thoroughly chilled while the other side was warm I was called out to bring my incubator on the third day After the incubator was raised to a temperature of 85 degrees, on unwrapping the baby I found it cold and stiff While the side toward the fire was red, the side away from the fire was cold and blue Many infants born at full term after being washed with water are then put in a cradle, and especially in houses heated with a grate, we will get a chill of the side away from the fire, and bronchial trouble and other affections will arise which will cause its death If the day is cold and chilly, I intend to insist upon keeping the infants in a box, or any way so they are comfortable and will not chill

Dr **Mary E Green**—Some one has said that two thirds of the diseases of after life are due to the malnutrition of the first two weeks of infancy I think that probably is largely true One man has made the statement that nine tenths of the children are fat starved In view of all these statements that have come to us as practitioners, it behooves us to consider what the diet whould be The Doctor very correctly said that the mothers should be educated along this line I have so often noticed the patent foods recommended during the first two months of life I believe that it is wrong to give the child any starchy food for the first six months of its life at least I believe the child's food then should be cream, or the upper part of the milk, with water one-half I like what the Doctor said about the sterilization of milk No child can remain healthy for a long time upon sterilized food There is a lacking principle, so the child does not thrive on sterilized food I think sterilization is unnecessary if perfect cleanliness is carried on in the preparation of the food Some experiments have been carried on in giving children modified milk But in all those laboratories absolute cleanliness is observed, and if as much cleanliness is practiced in preparing the usual food for infants, as good results will be obtained All the attendants are obliged to wear duck suits, and perfect cleanliness is observed The question of food is a very serious one up to the age of school life

Dr **E Stuver**, Rawlins, Wyo —I believe it was Holmes who once remarked that the education of a child ought to begin about two hundred years before it was born The child ought to have a strong healthy mother, a mother who can provide an abundant supply of the nutriment that nature has intended the child should have during the first year of its life I believe one of the most important points in securing good healthy children is to pay particular attention to the health of the child's mother, and after the child is born, if the mother has a disclination to nurse it, try to show her that is one of her duties as a mother to assume that responsibility Furthermore, I believe most of the patent foods do not supply what they should supply for the infant Take for instance our condensed milks A child may grow plump and apparently strong on condensed milk, but it is much in the same condition as the old beer drinker Let him contract a serious disease and he has four or five times as many chances to die as a person in good health The flabby, condensed milk baby stands a good many more chances to die than the baby that has been fed on good natural mother's milk

Dr **Brown** of Illinois—The problem which I think especially interests practitioners in regard to feeding infants has occurred in the smaller towns where we are without milk laboratories and where it is absolutely impossible to have any form of modified milk We are called into houses where children are dying of marasmus and malnutrition, where there is no ice in the house in the hottest summer months, where the milk is obtained from a milkman, carried several miles in hot cans on hot days before it reaches its destination To make a modified milk out of that is entirely out of the question I am in the habit of giving my better patients a formula for making a modified milk But in the poor and ignorant classes it is impossible to give any instructions they can follow We have to resort either to the patent foods or condensed milk In choosing one of the two evils I choose condensed milk, because it is the only way to get a food in the smaller towns I am in the habit of adding cream, because even if you get cream from milk in an unhealthy condition, carried around in tin cans three or four hours in the cities, the cream is less likely to be infected

Dr **Mary E Green**—I was going to make a remark about condensed milk There are condensed milks and condensed milks Some of those put up with sugar I think are objectionable, but there are condensed milks put up without sugar, and to those there is little objection I have seen children brought up on such condensed milk and they have done well Recently I attended the health exposition in New York Three hundred cows were presented by Dr Brush It was an exhibition of the care of the cows and the milk Dr Brush furnishes the milk at 14 cents a quart It is not sterilized or modified in any way The only thing about the dairy is absolute cleanliness That is the one thing I think we should advocate more than anything else Not long since I attended a dairy convention and I heard a dairyman make the statement that he did not believe there were any dairymen furnishing milk to the cities in the summer who did not use some antiseptic, especially boracic acid or some form of borax If that is so, I think it is something physicians should know and we should fight against it Whenever antiseptics are used they render the milk unfit for children We want milk from a herd of cows rather than from one cow, but let it be clean

Dr **R B Gilbert**, Louisville, Ky —The consideration of artificial food is secondary If the child can not have its mother's milk, then we have to use something else One thing is the condition of the mother furnishing the food for the infant There are many times her milk is injurious In a great many samples of milk this will be found to be true, if you examine it from day to day, and the doctor should do so continuously The same thing may occur in the cow that furnishes the milk I am glad to hear the statement that the milk should be taken from the whole herd rather than from any one cow Not only that, but the food the mother eats has much to do Food that contains pickles or anything of that kind, or food such as onions, will affect the milk Mental anxiety will often modify the milk for several hours so the infant can not digest it I do not know what the process is, but there is an excess of the casein and a diminishing of the peptones in a fit of anger or anxiety of any kind, or grief, as from a misfortune, for instance It goes without saying that alcoholic stimulants all modify the milk One case in particular comes to mind, of a child 6 months of age, that died while under my care The mother went over in another part of the city to do a day's washing On her return home she smoked an old strong pipe more than two thirds of the distance home Immediately after nursing the infant became limp, decidedly feeble, and I could hardly understand why it was so It looked like it had been poisoned On inquiry I found she had used two or three pipefuls of strong tobacco in smoking, and I attributed the death of the child to that In reviewing the whole subject, you can not find any food, in my estimation, that is equal in any respect to the mother's milk

COLPOPERINEORRHAPHY AND THE STRUCTURES INVOLVED

DEDICATED TO DR THOMAS ADDIS EMMET AND MR LAWSON TAIT IN RECOGNITION OF THEIR LABORS IN THE SURGERY OF THE PERINEUM

BY BYRON ROBINSON, B S, M D
CHICAGO ILL

Concluded from page 925

Relaxed vaginal outlet, concealed lacerations or deep musculo-fascial tears of the pelvic floor, can not be too forcibly brought to the notice of the physician as an important diagnostic indication for colpoperineorrhaphy Kelly calls such, concealed relaxation

This is a condition of loose, gaping vulva, compared to the mouth of a bag without its puckering-string by Dr Emmet If the patient lie on the back the fork of the buttocks looks flattened, the anus appears everted, and one may observe the vaginal mucosa bulging out above or below The condition is frequently described as rectocele or cystocele, or both Others call it perineal laceration Some will write that it can not be perineal laceration, because the skin perineum is longer than the normal one The skin perineum is longer than normal because, when it was stretched at labor, it never returned to normal (subinvolution) Occasionally one can introduce the four fingers of the hand and put the long relaxed perineum on a stretch It is in these long, lax skin perinei that physicians disagree as to conditions, the one asserting that the perineum is plenty large enough and does not require an operation, while the other rightly asserts that the perineum is but a small part of the support of the sexual organs The fact is, the whole vagina and sphincter apparatus has become deficient, the vulva pouts, the anus everts, and the floor of the pelvis flattens out If the patient is requested to bear down, the anterior and posterior vaginal walls will roll outward, often to an astonishing degree By the act of straining, the cervix can be felt descending The patient has utero ptosis The sacro pubic hernia is more marked if one examines the patient in the standing position By careful inspection and palpation while the patient lies on the back, one may feel the retracted cicatricial stump ends of the lacerated levator ani muscle, and by irritating the little cicatricial elevated or depressed stumps we can see the contractions and relaxations in them Sometimes the perineum or lower posterior vaginal wall is so [illegible] that it is large enough to close up the

The horseshoe loop of the levator

the resis

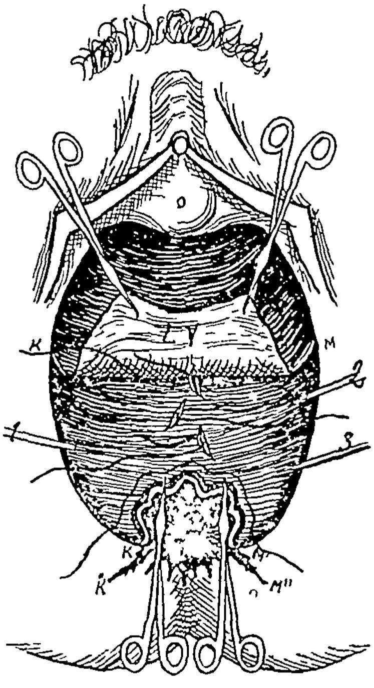

Fig 46—Advanced stage of the flap splitting operation L, V anterior vaginal flap held up by forceps, the posterior rectal flap is held backward by forceps the most posterior suture is placed along the margin of the torn rectum other sutures are being introduced by being threaded in the median line and drawn out Note that the needles do not penetrate the skin or mucosa

in the middle one feels an irregular sharp edge of narrow dimensions Also the loops of the levator are more displaced to the side of the vagina Though the patient can generally control stool, yet the vigorous elasticity of the muscular loop is definitely impaired With the patient on the back and the two index fingers in the vagina, one can quickly test the degree of deficiency of the sphincter vaginal apparatus by pressing downward and backward The vulva may pout with perineal skin intact, and the same may be said of the rectum The fascia and levator ani may be quite defective on one side and intact on the other side In very sensitive women, made worse by long-continued irritation, the examination is occasionally delusive, because reflex irritation puts parts on a tension

We may classify the operations for colpoperineorrhaphy into three general divisions, viz posterior median colpoperineorrhaphy, posterior bilateral colpoperineorrhaphy, and the posterior flap colpoperineorrhaphy Some of the principal originators and advocates of posterior median colpoperineorrhaphy were Dieffenbach, Langenbeck, Baker-Brown, Osiander, Simon, Hegar, Hildebrandt, Jobert, DeLambelle, Le Fort, Schroeder, Werth and Reamy

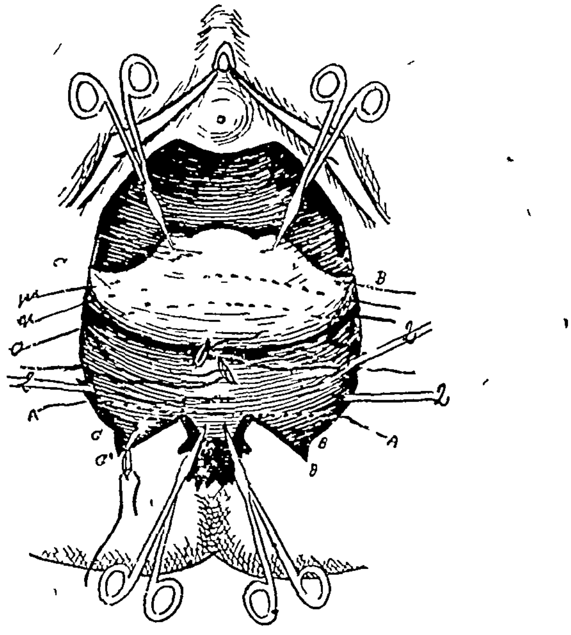

Fig 47—Another stage of flap forming Observe that the most posterior suture is being introduced by the needle passing from one side of the denuded wound to the other because the space is short but the denuded surface under the flap is generally so wide that it is most practical to pass the handled needle from the lateral margin of the wound to the median line where the needle is allowed to emerge and become threaded Thus the sutures are passed through half of the wound at one time

The chief originators and promoters of bilateral colpoperineorrhaphy are Emmet, Staude, Freund, Martin, Bischoff, Goodell and Kelly Some of the pioneer originators and advocates of the posterior flap colpoperineorrhaphy were Langenbeck, Duncan, Tait, Jenks, Voss, Simpson, Marcy, Colles, Sänger

Whatever the apparent differences of the above three classes of procedure, all the advocates practically agree that definite denudation (flap or otherwise), exact approximation of wound surfaces, and d[illegible] sutures (without tension), based on anatomic

prerequisites of success Methods

are not so important as attention to

l principles The physiology of

d by an overstretched perineum or elongated supports (enteroptosis), it must be restored by reproducing as near as possible anatomic integrity.

The relaxed tissue must be corrected with deep sutures and dissection, the blood-vessels must have a definite supporting bed in which to functionate, the peripheral nerves must be protected against continued repeated trauma, and the organs must assume a normal position, all of which belongs to the domain of colpoperineorrhaphy. The genius of Emmet established the utility of surgical procedure in the vaginal sulci. The grand operations of Bischoff sparing the posterior vaginal column (or median vaginal surface) foreshadowed and aided Emmet, as well as the scholarly labors of Schatz on the pelvic floor. As a pupil of A. Martin in 1884, I saw the contemporaneous and independent development of Emmet's operations in the vaginal sulci, in the hands of the most skilled gynecologic surgeons of Germany.

It may be remembered that the Emmet and Tait operations are alike valuable in operations for relaxed vaginal outlet, with the advantage in the Tait operation of a flap to protect the wound. The reason Emmet's operation is about of equal value is that healing in the vaginal sulci is almost certain, hence but little danger of loss of valuable tissue by non-healing. Nothing is gained by denuding an area of vagina over retaining that same area intact, for it will contract to its original size shortly after the tension which produced it is removed.

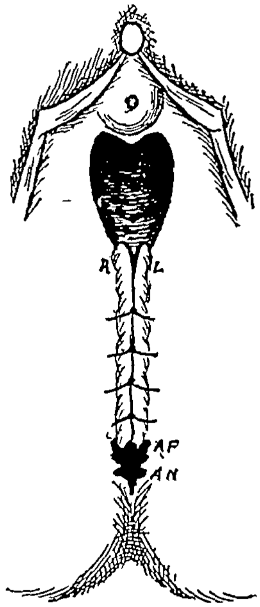

Fig. 48.—Finished operation in a case of complete laceration. R, L, anterior end and A. P. posterior end of newly built perineal raphe. A, N, ossus ani is a little patent.

The rational symptoms resulting from lacerations requiring colpoperineorrhaphy are very numerous and varied, but they follow a logical sequence. In general the chain of symptoms is as follows. A local point of irritation—an infection atrium, reflex irritation which unbalances the other viscera (abdominal and thoracic). The irritation, from a focal point, travels up the hypogastric plexus, the ovarian plexus and the lateral chain of sympathetic ganglia to the abdominal brain and thoracic plexus, which aids in disturbing the visceral rhythm. Anatomic facts must be inspected. We find on each side of the uterus a large ganglion, a massive collection of nerve cells which has been termed the cervico-uterine ganglion. We may call it the pelvic brain. An enormous mass of nerve-cells—the abdominal brain—is found at the root of the celiac axis, just behind the stomach. Three great ganglionic masses of nerve-cells are found in the neck (superior, inferior and middle cervical ganglia), and a vast, intricate network of nerves in the heart—Wrisberg's plexus. Each of these large ganglionic nerve masses is in intimate and close communication with the genital organs. Many strands of nerves connect each ganglion with the pelvic viscera.

It is the numerous nerve strands which play the important rôle, because many strands, tracts, will carry many messages, and a few ganglion cells can take care of innumerable peripheral reports. A few ganglion cells will receive and dispose of many messages from many lines. Now the ganglion cells—the thoracic, abdominal and pelvic brains—assume a certain control over the rhythm of their respective viscera. Hence the viscus which is the most intimately connected to those three brains by many nerve strands will exercise significant power over the rhythm of the organs. One of the chief functions of a viscus is rhythm. If this be disturbed the organ becomes defective and fails in its final object.

Let it be remembered that the irritation from a diseased organ is emitted at all times, without regard to

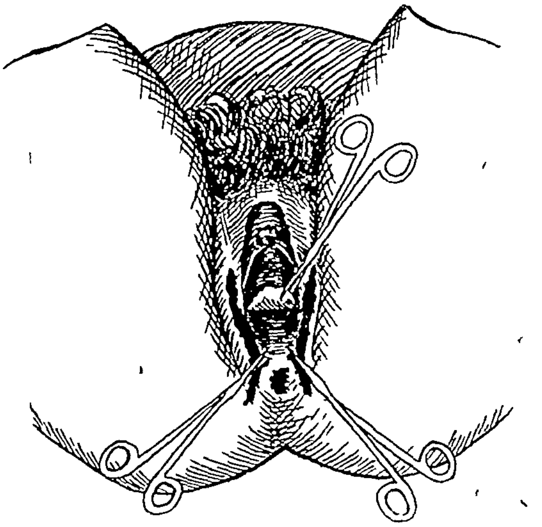

Fig. 49.—(Author.) Method of forming the flaps with a non complete laceration with anterior and posterior "cuts" and vaginal flap.

physiologic rhythm by which the organ accomplishes its mode of life. The occasion of rhythm is the natural stimulus of an organ, as food for the digestive tract, air for the lungs, blood on the endocardium, urine in the urinary tract, a fetus in the uterus, fluids in the Fallopian tubes, and food material in the liver, carried to it by the portal vein. If we follow a diseased message emitted from the pathologic genitals up to the abdominal brain over the lateral chain—the hypogastric ovarian plexus—where it is reorganized and emitted to the digestive tract, we may observe the following disturbances. Excessive secretion in the digestive tract, deficient secretion, disproportionate secretion. Excessive secretion may induce diarrhea, deficient secretion, constipation, and disproportionate secretion may produce fermentation (bloating), the continuation of such reflex factors institutes indigestion. The reflex irritation, passing from the diseased genitals to the abdominal brain, is reorganized and transmitted to the liver over the hepatic plexus. This pathologic irritation produces excessive, disproportionate or deficient secretion in the liver The liver secretes bile, glycogen and urea It has a rhythm, just as the heart or lungs

The transmission of pathologic irritation—reflex irritation—to the liver unbalances its rhythm and disturbs its secretion If the rhythm of any organ be disturbed its function will soon become defective For example, the rhythm of the small intestines is governed by the superior mesenteric ganglion, which induces a rhythm four to six times daily, according to food indigestion Improper foods, disturbing the regular rhythm, soon induce indigestion The descending colon, sigmoid and rectum (the fecal reservoir) is controlled by the inferior mesenteric ganglion, which makes a daily rhythm The superior mesenteric ganglion has a four- to six-hour rhythm, while the inferior mesenteric ganglion has a 24-hour rhythm Any one knows that disturbing the rhythm causes constipation, and eventually many neurotic symptoms arise Long continued indigestion produces malnutrition Pathologic irritation passes to viscera at all and any times, in season and out of season, day and night, while organs are attempting to rest or to pass through a rhythm, always causing disturbances Organs secure rest and repair between rhythms

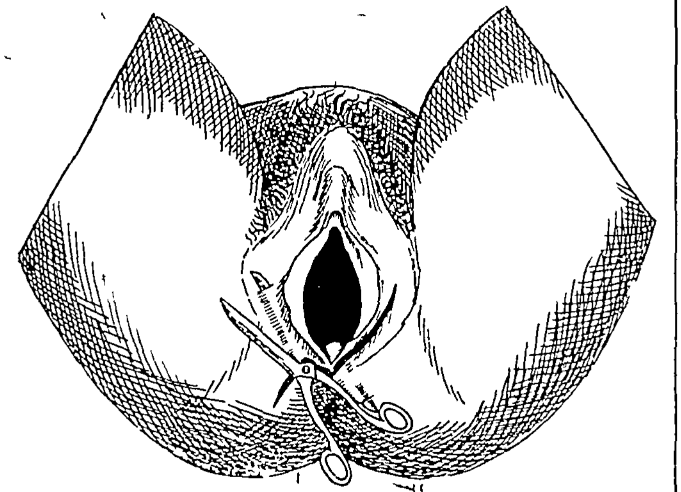

Fig 50 —(Robinson Scholer) The flap formation On the right the scissors are shown forming the anterior cut on the left the blade of the scissors only is shown forming the posterior 'cut ' beside the rectum

Malnutrition is followed by anemia—a disproportion between the blood vessels and plasm Long continued anemia is followed by neurosis The numerous ganglia are bathed in waste-laden and irritating blood Innumerable local and distant neurasthenic conditions are manifest We have, then, as a train of evil symptoms following genital defects 1, local irritation—an infection atrium, 2, reflex irritation to the abdominal brain, where it is reorganized and sent out to the various viscera, 3, indigestion and malnutrition, 4, anemia, and 5, neurosis

In the incomplete cases of laceration the disturbance is attributed to gaping of the vulva and the consequent favoring of rectocele and cystocele This condition is followed by uterine prolapse, endometritis and metritis The patient suffers from ill defined pains while standing and walking These patients complain in a manner similar to that of those who are afflicted with enteroptosis When the lacerations become complete, not only a physical defect of control of feces and g exists but a train of mental symptoms follow co plete lacerations or serious lesi ly aff life, both and

easily fatigued, neurotic constantly, liable to exacerbation of infectious processes

One of the most unfortunate results of extensive laceration of the rectovaginal septum is diarrhea When the sphincter muscles have been so far drawn apart at the ends that they are almost a straight line, the rectum has lost all control of feces A straight sphincter is a symptom of complete laceration, the diarrhea accompanying the straight sphincter is very exhausting The amount of separation in the sphincter muscle tells the story of the degree of laceration When one can find the deep dimples in the skin, on each side of the gaping vulva, due to the cicatricial ends of the muscular bundles contracting it may be estimated that the vaginal sphincter is extremely defective and that over half of its arc is wide open Only a carefully planned operation can relieve this condition The widely gaping vulva is exposed to much trauma and consequent infectious processes The congested genitals and rectum produce excessive glandular secretion, which furnishes a culture medium not only to the pathogenic bacteria, but tends to multiply the regular residents of this locality into excessive number, and in all probability dangerous kinds, for doubtless bacteria rapidly change from one kind to another by change of food and temperature It would be strange indeed if all the scores of uterine tubular glands could long remain normal with frequent congestions and decongestions Excessive bacteria in any locality must produce their dangerous toxins, which become absorbed and carried away by the veins and lymphatics The rectal veins are known to stand in direct communication with the liver by way of the valveless portal system Hence may be observed the vicious circle established by the defective sphincter apparatus of the vagina Again, consider the innumerable reflexes which must necessarily arise from the infected, frequently congested, occasionally acute, inflammatory invasions of the genitorectal organs These reflexes arise in all degrees and conditions, and the patient almost imperceptibly passes through the stages of indigestion, malnutri- nia and neurosis Again, many of these operated on by inexperienced surgeons, t imperfect results Then a conflict as to the perineal defect being the

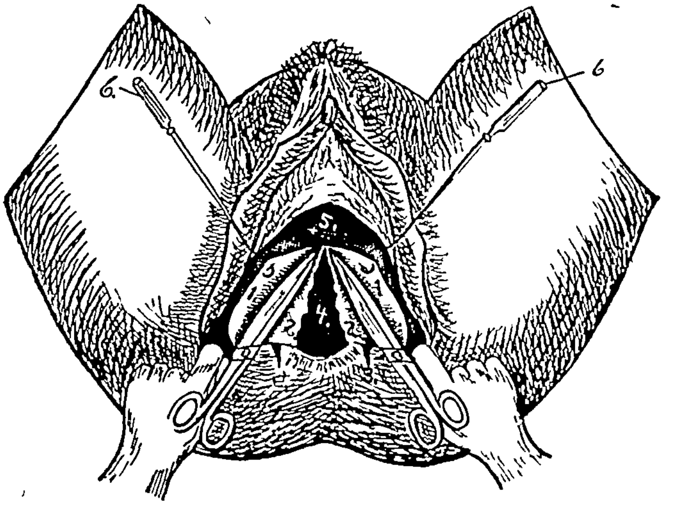

Fig 51 —(Robinson Scholer) Flap formation with the scissors at the bottom of gutter between rectal and vaginal flaps 1 1 vaginal flaps held aside by the shepherd s crooks 6 6, 2 2 rectal flaps 3 3 back cuts ' 4 rectal lumen 5 outline of cervix This represents a complete laceration high up into the rectum

cause of the trouble or whether the etiology is to be located in the nervous system, for one of the evils of today is the confounding of nervous and genital diseases After an imperfect operation on the genitals, with a consequent imperfect result, the operator is liable to throw the whole defect on the nervous system As the nervous system and the liver are the chief scapegoats of ignorance (and knavery) it is difficult to demonstrate the error It requires wisdom, knowledge and experience to discriminate between genital diseases and their consequent train of neurotic effects, and the diseases which definitely belong to the nervous system itself or to other causes than the genitals I must insist, however, that this requires more time and skill than any general surgeon or physician is able to give

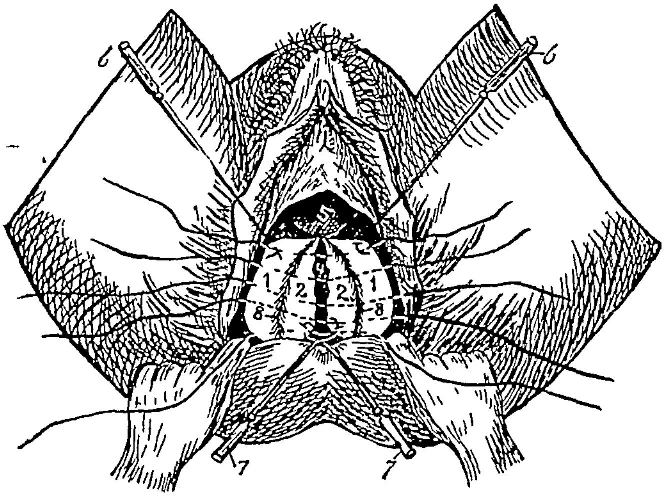

Fig 52 —(Robinson Scholer) The sutures in position in a case of laceration high up into the rectum 1 1 the vaginal flaps held aside by the shepherd's crooks 6, 6 2, 2 rectal flaps held in place by the crooks 7, 7 8, 8 points to the line or angle of junction between the rectal and vaginal flaps

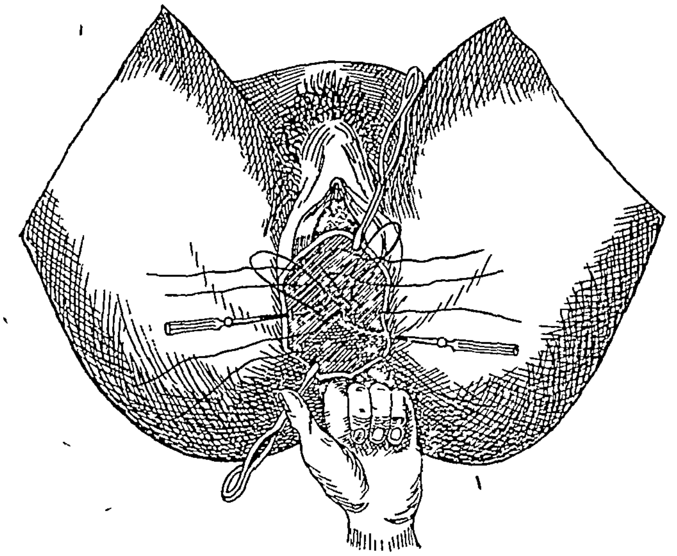

Fig 53 —(Robinson Scholer) A case not ruptured into the rectum in which the sutures are in position The sutures are threaded from the median line as seen in the cut Observe that the sutures penetrate neither skin or mucosa

Until one comprehends the practical anatomy, it is almost impossible to interpret the rational symptoms of the deficiency of the supports of the sexual organs The popular view of general physicians that the perineal body is the chief support is one illusion which I find, after considerable experience in teaching, difficult to eradicate It is the indefensible mechanical theory that the perineal body is the keystone, the cork which stops the bottle, or the wedge which plugs up the pelvic outlet Unfortunately a prominent American gynecologist at one time abetted this false theory

One of the very common diseases accompanying perineal lacerations is endometritis Little need be said to defend or explain this condition, for it is evident to all observers how the endometrium may be insulted by trauma, congestion and bacterial invasion, when unduly exposed from deficient support Excessive glandular secretion arises, leucorrhea, which may be non-infective, then pathogenic infection soon follows with its consequent train of evils

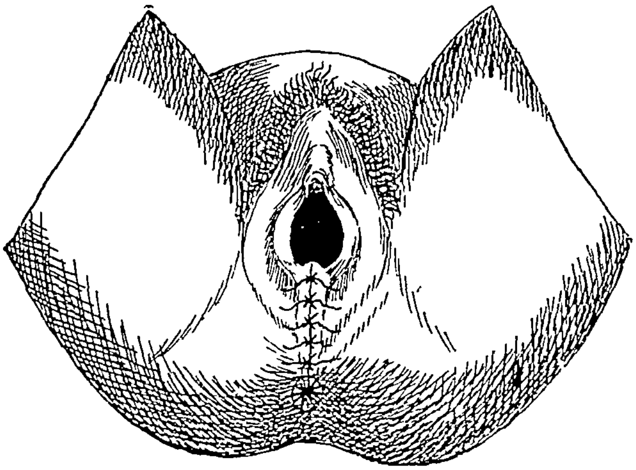

Fig 54 —(Robinson Scholer) Completed operation on an incomplete laceration Five sutures were employed

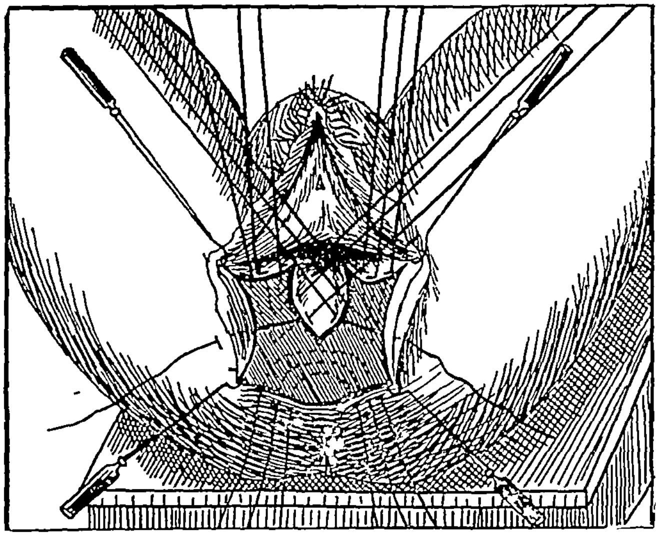

Fig 55 —(Robinson Scholer) First stage of Dr Emmet's operation, viz Denudation of the posterior vaginal wall denudation of a triangle in each sulci of the vagina, with the noted method of his peculiar suturing

This leads me to a subject of vast importance It is the metritis (subinvolution) which so frequently accompanies laceration of the perineum The general practitioner calls it subinvolution But we will call it metritis, because we believe it to be of microbic origin Be it remembered, the uterus above all organs is liable to infection, because its glands pass directly into its muscular walls It has no submucous layer or barrier to protect the muscle The intestine has a submucous muscular layer which acts like a barrier against microbe invasion But the uterus has no muscularis mucosæ It has no barrier between its glandular apparatus and its muscular apparatus, so that microbes or their products which gain the uterine glands soon gain the muscular walls of the uterus and produce metritis Hence metritis is one of the frequent accompaniments of perineal laceration, and as metritis is a very chronic disease, it is apt to continue even beyond the repair of the perineal injury

From this short view it may be observed that the rational symptoms of injuries to the pelvic floor are generally a train of evils which increase with time, and the final brunt is most apparent in the nervous system Many of the symptoms can only be accounted for by carefully noting the many cases of invisible lacerations—the relaxed pelvic floors, perineal supports and sphincter vagina apparatus—which disturbes circulation by the vessels being torn from their proper fascial beds, the veins becoming elongated, dilated, straight, and losing their normal spiral form, and the nerves being put on the stretch or traumatized

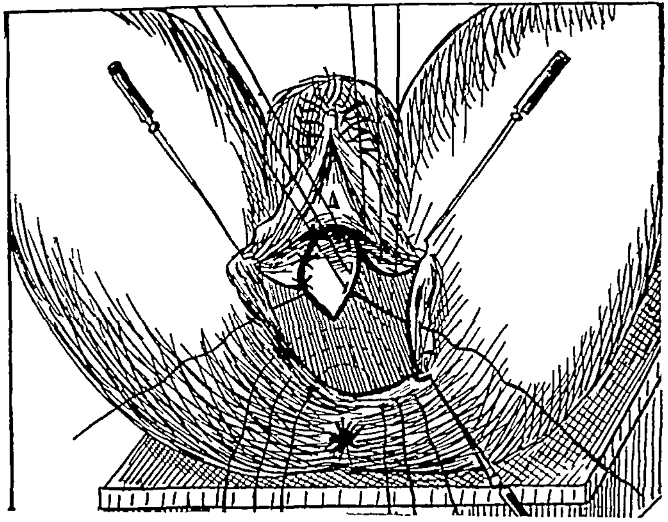

Fig 56 —(Robinson Scholer) Another stage in which the triangle in the right vaginal sulcus is closed with two sutures sutures in position

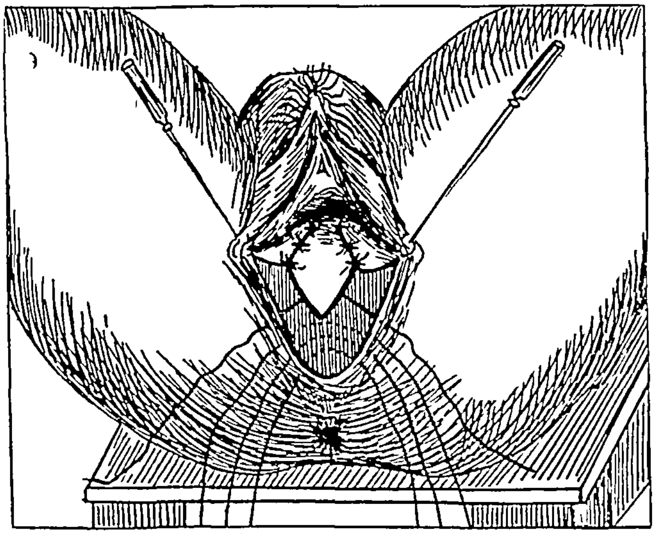

Fig 57 —(Robinson Scholer) The two denuded triangles closed by sutures the remaining sutures in situ

We thus have disturbed vascularization, congestions and decongestions of blood and lymph have also disturbed innervation from traum ed es En-
teroptosis exists and the ave are
widely exposed The supports
been overstretched by one
not resumed their norma
such patients,
cleft is flatt

broad and shallow and the anus, instead of being drawn up under the pubic arch, appears flat, exposed, and fallen back toward the coccyx The skin perineum may be much larger than normal, being overstretched The finger introduced into the vagina no more feels the rigid levator ani muscle loop, but in its stead the relaxed, overstretched, flabby tissues lying between the gap made by the separation of the levator ani fascia superior and inferior with its contained muscle in various degrees Perhaps there is no lesion more overlooked in the pelvic floor by the general practitioner than the relaxed, overstretched outlet In 1883 Emmet and Schatz first clearly announced their views in regard to relaxed pelvic outlet The very deep perineum is deficient, while the shallow, short one is the vigorous one The patient with relaxed pelvic outlet generally begins to complain of bearing-down symptoms on rising from bed some two or three weeks after labor She feels weak, unable to work or exert herself, pain in the back, general lassitude and prostration

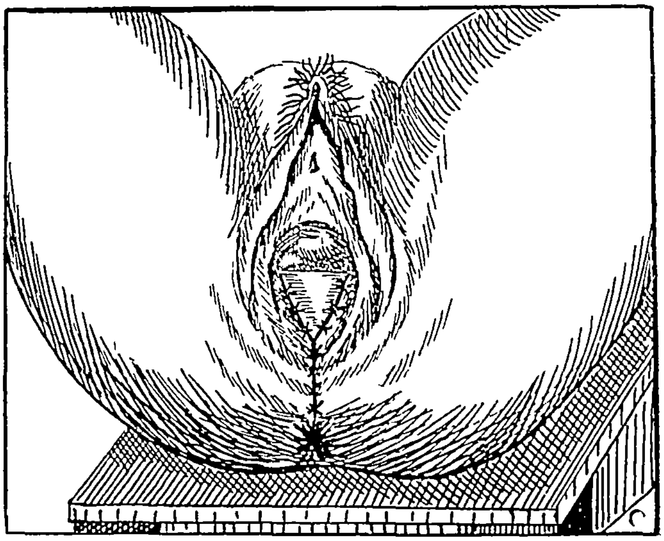

Fig 58 —(Robinson Scholer) Operation finished The Y shaped line shows the line of suturing

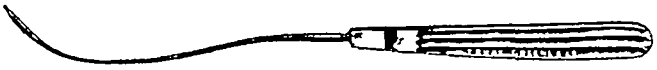

Fig 59 —Author's perineorrhaphy needle

The relaxed pelvic floor is most impressive to the operator, by examination before and after the anesthetic, when he is about to operate Before the anesthetic the pelvic outlet is held in partial tension by the remnants of the muscular and fascial supports, the loops of the levator ani muscle being irritated by the non-balance of parts being torn, the patient is constantly losing nerve force by the attempts of the reflex irritation in keeping up the tension When the patient is fully anesthetized the parts of the pelvic floor show vast relaxation and it becomes at once apparent to the hand and eye of the operator that a significant defect exists, beyond his expectation, in the sexual apparatus The perineum falls back, the anus flattens and everts, the vaginal walls roll outward, and
p a -urrow assumes a plane approximating
ks Vast changes in subcutaneous
ports have occurred, capable of
by an operation which restores
nerves to a protected sheath,
n which will insure normal
on—in short, proper nour-

ishment With such patients in the erect posture the intra-abdominal pressure is continually displacing the viscera by forcing them into and through the weakened pelvic outlet The pelvic outlet, beyond the normal floor is full of prolapsing organs which often deceive the practitioner by closing up the gap

The length of time allowed to relapse between the injury and the operation on the perineum should not be less than three months The parts do not heal well shortly after labor Old gynecologists, as Byford, recommended at least six months to elapse before the operation should be performed Perhaps four months after injury it would be fairly safe to operate The old cicatrix can not always readily be found, but by pulling on the vagina in various directions the puckering tissue about the scar will be discovered The palpating finger may also find it

The cicatrix produces new points for the attachment of the torn fibers of the levator ani muscles which may give the outlet a peculiar, irregular, puckered appearance when the muscular bundles contract from their new points of attachments The flap formation should extend beyond the cicatrices so that the ends of the muscular bundles may be included in the sutures The time for operation should be midway between the menstrual periods

In regard to the perineal body The posterior curve of the vagina must be reproduced by restoring the rectovaginal septum

A new perineal body should be restored, so that the natural backward curve of the vagina should persist, i e, normal relations should be established between the perineal center of body on the one hand and fascia on the other" The perineal body, the punctum fixum of vulvar surface relations, should be restored

In writing this essay I have derived aids and suggestions from all accessible authors and have attempted to duly credit the labors

Some suggestions were acquired in regard to drawings from the book of W J Stewart McKay

SOCIETY PROCEEDINGS

The Chicago Society of Internal Medicine

Second Regular Meeting, Sept 21, 1898

Dr John A Robison, the president, occupied the chair, and delivered the Presidential Address to an audience of 156 members and visitors After briefly outlining the object and aim of the Society, he directed attention to

A CLINICAL STUDY OF FIFTEEN CASES OF MALARIA

He referred to the various forms of organisms and what relation they bear as etiologic factors in the production of the various forms of malaria

1 There is the flagellate form of the parasite, concerning whose age and mode of production observers are not yet agreed It is seldom observed, but sometimes may be found in the blood a few hours after febrile paroxysm, or less often during the afebrile It is the small, pale, movable body, having from one to three extremely delicate, pigmented, thread like processes, which are the locomotive organs of the parasite It is generally ecto globular Some observers believe the flagellate organisms are young organisms, others claim they are not degenerate forms, and a great many authors maintain they do not exist until after the blood is exposed to the air It seems to him the claim that they are young organisms would stand best for the reason that they are provided with flagella which permit them to seek their prey — the red blood corpuscles Sakharoff and Danilewsky believe they are a separate species of organisms, since they possess a very large nucleus, while the non flagellated forms have small nuclei They are more frequently observed in the irregular forms of malaria

2 The parasite of tertian malaria The ecto globular parasites invade the red blood corpuscles, and are seen as small, pale, hyaline ameba, sometimes star or cross shaped Sometimes no pigment granules are noticed, or one may see a few scattered, peripherally placed granules Repeated observations show that the bodies have grown at the expense of their host, the pigment granules are more marked, and display very active movements At the end of forty eight hours there may be from six to twenty granules, and the blood corpuscles have lost their coloring matter and they look like thin translucent cells Segmentation now occurs, and this process precedes or accompanies the chill or fever The pigment granules become motionless and collect in the centers of the amebæ, and lines of striation stretching toward the periphery through the finely granular protoplasm cause the organism to have the appearance of a rosette The segmentation proceeds until it is divided into eighteen to twenty spheres, the shell of the corpuscle bursts, and the small, rounded hyaline bodies, each being a translucent bit of protoplasm, with a highly refractive central spot, are set free in the circulation, being doubtless the spores which develop into the plasmodia The cycle of development requires two days Two groups of tertian parasites maturing on alternate days may cause the quotidian form of the fever

3 The quartan form of parasite In the quartan form of fever the pigment granules are larger, blacker, and the ameboid movements are more sluggish Their growth does not decolorize the corpuscle to the same extent, nor do they fill the corpuscle so completely They mature in from sixty-four to seventy two hours, and, while they occupy the greater portion of the corpuscle, they are surrounded by a rim of colored stroma The segments seldom reach twelve in number, and they eventuate in small spherical or ovoid bodies The quartan organisms may mature in two groups on successive days, with one day's interval between (double quartan fever), or three groups may mature on successive days, producing a quotidian form of fever (triple quartan)

4 The estivo autumnal or irregular forms of fever According to Osler, "the early form of the estivo autumnal parasite is not unlike that of the tertian and quartan varieties, but the hyaline body is mooring like, more highly refractive, and the central part often looks shaded, as if a more solid body were enclosed within a vacuole As this form increases, the ameboid movements are well seen The pigment is in small amount, at first, in the form of one or two very dark granules at the margin of the amebæ, and the pigments never so abundant as in the tertian or quartan forms The organism rarely occupies more than one third of the corpuscle, the stroma of which is never entirely decolorized On the contrary, it often presents a peculiar brassy, green appearance, and looks shrunken or crumpled The cycle of development of this form is rarely carried out entirely in the circulating blood, but the bodies with centrally placed pigment are not uncommon The observations of Italian observers seem to show conclusively that the segmentation takes place in the spleen, the bone marrow and the internal organs The length of time of its cycle of development has not been determined Probably groups mature at varying intervals of time The fever associated with this organism is characterized by irregularity, the paroxysms are not at definite periods, and the pyrexia may be more or less continuous, with remissions In the irregular form of the fever may be found the crescents of Laveran Sometimes they are sickle shaped, oval or circular, and provided with flagella

Technique —In examining for plasmodia two methods may be used 1, the fresh unstained blood may be placed between a cover glass and a slide, 2, the blood may be dried and stained In obtaining the blood for the first method square cover slips and slides must be thoroughly cleansed, so that the blood will spread evenly and not form rouleaux, which would conceal the plasmodia if present A small drop of blood should be used The slide and cover slip should be arranged at the side of the bed so they can be handled without touching the surface of the glass The ear is cleansed with water and alcohol, allowed to dry, and then punctured The cover slip is touched to the apex of the blood drop and quickly dropped upon the slide, when the blood will be quickly spread and may be examined with a one twelfth oil immersion lens In some cases it may be necessary to use the dried specimens, if a microscope is not accessible, the weather is cold, or you wish to confirm your diagnosis with the fresh blood examination

To obtain the blood for staining use two cover slips and touch the apex of the blood drop with one, and drop it on the other cover slip, and after the blood has stopped spreading, gently separate them by sliding the one off the other in the plane of their surfaces These preparations are then allowed to dry in the air and are afterward fixed by immersing for a period of one to twenty four hours in equal parts of alcohol and ether The simplest form for staining the dried slips is with eosin and methylen blue, the eosin staining the red blood corpuscles, and the methylen blue staining the plasmodium The specimen should then be melted in balsam and can be kept indefinitely

In examining the fresh specimens certain conditions are apt to confuse one, if inexperienced These conditions are 1, conditions brought about by the refraction of light, which gives the appearance of a hyaline body regularly and sharply defined, 2, vacuolated red blood corpuscles, 3, crenated red blood corpuscles In the first case, there are usually in the field a larger number of the seeming hyaline bodies than we would hope to find of plasmodia By focusing with the fine adjustment it will be found that these bodies increase and diminish in size, whereas the plasmodium does not vary in size, but grows dimmer and becomes clearer as the red blood corpuscle is found in or out of the focus The outine of the plasmodium is usually rather indistinct and seems to merge into the protoplasm of the corpuscle, being situated in most cases between the center and the periphery of the corpuscle, and not in the center, as is the case with the so called refractive bodies In the second of these conditions the points of differentiation just mentioned will serve to affirm or exclude the presence of the corpuscle, while in the case of the crenated corpuscles it will be found that the corpuscle has a jagged edge and that the above stated features of the plasmodium can not apply

Dr Robison then details fifteen cases of malaria, two of which were sporadic, and the other thirteen were epidemic and occurred among the returned soldiers of the late war

Case 1 —W G , age 38, single, farmer, German descent, lives north of Grossdale on the banks of the Salt Creek, where two cases of malaria have recently developed He worked in the fields harvesting, but Friday, September 2, felt weak and sweat profusely Sunday, September 4, was compelled to remain in bed on account of extreme weakness and vomiting Tuesday morning, at 6 A M , patient had a chill lasting twenty minutes, followed by high fever and sweating Thursday at 1 A M , chill lasted an hour, fever and sweating, accompanied by delirium Entered Presbyterian Hospital, September 8 Spleen palpable on the 9th Blood examination on the 9th at 3 P M revealed the presence of a crescent, endoglobular and octoglobular plasmodia The patient was discharged on the 14th, not having had a chill nor a temperature above normal, nor had he taken any quinin It was a case where the infection was resisted without the use of quinin

Case 2 —D P , age 18, male, single, Greek, lives in Chicago Four months in America Never was ill before Tuesday, September 6, had a severe chill at 2 P M , accompanied by headache backache and anorexia Entered the hospital, September 9 at 4 P M , temperature 104 2 degrees F , pulse 100 At 3 A M , September 10, the patient was restless and delirious At 9 A.M the blood examination revealed the presence of crescents This patient evidently is one of those who receive their infection in one country, and it is develbped later in another, as he doubtless was infected in Italy, and the infection did not develop until he lived in Chicago a while Received Warburg's Tincture Discharged cured September 20

SOLDIERS

Case 3 —Tertian fever J D , age 34, single, Company M, First Illinois V I Had yellow fever in July at Siboney Was taken ill Monday, September 12, at 10 A M with a chill lasting two hours, very severe and followed by fever and sweating Wednesday, had a second at 10 A M Was admitted to the hospital, Thursday at 4 P M At 5 P M temperature was 104 degrees F Friday at 4 P M had a chill lasting half an hour The spleen was palpable At 8 15 A M Friday, a blood examination revealed a few endoglobular plasmodia, with scant pigment granules sluggishly motile The patient responded promptly to quinin

Case 4 —H J , age 25, single, Company K, First Illinois V I Gives history of two complaints 1, Six weeks ago, while in Cuba, had chills and fever which yielded to quinin in four days Two weeks later had an attack lasting three days, and two weeks later was ill two days That attack commenced with one paroxysm of chills and fever, no recurrence of the same taking place until the effect of the quinin wore away 2. Four weeks previous to entering the hospital he was attacked with severe pains in the bowels, with looseness of the bowels Has averaged about twelve stools per day ever since The stools are dark brown unformed, slimy, 2 a light gray

with blood, 3, a light brown, 4, white and like

few days, and at the present time are returning

appearance The spleen is slightly en

ination at 11 A M 14,

large endoglobular plasmodium, the blood corpuscle decolorized with pigment granules having a sluggish movement September 15, at 3 P M , he had a chill lasting twenty minutes, and the temperature after the chill was 104 degrees F A similar occurrence took place at 3 P M on the 16th There has been no chill or fever since the exhibition of quinin This is undoubtedly a double tertian

Case 5 —S J , age 20 single, Company L, First Illinois V. I Taken ill August 30 with chills just before leaving Cuba Had chills every night until after treatment at a hospital in Brooklyn One week previous to entrance into hospital, had been walking about, although very weak Had slight chills about 5 P M , September 18, 19 and 20, followed by a temperature of 104 degrees F September 20, at 1 15 P M a blood examination revealed, 1, numerous small endoglobular plasmodia with small fine, very active pigment granules, and 2, large endoglobular plasmodia with coarse, sluggish granules This apparently is a case of tertian and quartan malaria, the paroxysms developing daily It would be natural to suppose it is a case of double tertian, or triple quartan, were it not for the character of the plasmodia found

Case 6 —A E H , age 32, single, Company H, First Illinois V I Had yellow fever in Siboney early in August Sunday, at 8 P M , September 10, had a chill, and has had one every day since Was admitted to the hospital September 15, and had a chill at noon lasting half an hour The chills recurred September 16 and 17 Ehrlich's reaction was found September 18, a blood examination at 8 A M revealed very small endoglobular plasmodia, with fine pigment granules One very small ectoglobular body with very fine, scarcely discernible, pigment granules There has been no chill since the 18th, after placing the patient on quinin It is undoubtedly a case of double tertian

Case 7 —J F , age 21, single, Company F, First Illinois V I Early in August he found himself gradually losing strength One day went to bed, and the next day at noon had a chill The chills recurred at that hour for four days Resumed work in ten days, and has been able to be up and around ever since, until September 12, when he had a prolonged chill at night Entered hospital, September 13 The spleen was palpable Has had no chill since September 14, at 11 30 A M , the blood examination revealed endoglobular plasmodia, the corpuscular protoplasm decolorized, and of hyaline appearance Fine pigment granules, with active motility The corpuscle was enlarged one and one sixth, the plasmodium occupying four fifths of the corpuscle, and well outlined Double tertian

Case 8 —J C , age 33, single Company H, First Illinois V I Had typhoid fever eleven and four years ago Was taken ill with a chill September 17, lasting from 3 A M to 11 A M , followed by very little fever or sweating, and the patient has been having daily chills of differing severity at various times of the day, sometimes in the morning, and sometimes at night Entered hospital, September 18 Spleen palpable Blood examination at 2 P M revealed an ectoglobular body, one-third of the diameter of a red blood corpuscle, with six sluggishly motile pigment granules, and a crescentic, endoglobular body, with small, fine, sluggish pigment granules This is apparently a case of triple quartan Quinin has proven efficacious

Case 9 —C C K , age 21, single Second U S Cav While in Cuba suffered from chills and fever of an irregular type Had not felt well since landing in New York Had a chill severe in character, lasting one hour, at 7 A M , September 11 Had a second chill September 12, at 1 P M Entered hospital, September 15 Temperature at 11 P M was 103 4 degrees F September 16, at same hour, was covered with profuse cold perspiration A small and young endoglobular parasite, which has undergone fusion, one segment containing motile pigment granules September 17, at 4 P M , the temperature fell to 96 6 degrees F , and it has remained subnormal reaching 98 degrees only once since He has aching pains in the legs, but otherwise feels very well This case belongs essentially to the asthenic and adynamic form of the fever, prooably of the tertian variety

Case 10 —J W M , age 25, single First Illinois V I This patient was formerly a private patient of mine, whom I had sent to Colorado for incipient tuberculosis He remained there all winter, and when the war broke out, he came home and enlisted in the army Was taken ill in Cuba about the middle of August with dysentery and fever Had no chills, but was weak and dizzy Two weeks after boarded the transport *New York*

the sick contin with weakness, diarrhea and

but h arrived in Montauk, August

for days, all symptoms

eared Arrived in Chi

of severe suffering on

the train, being extremely weak and feverish Entered the hospital September 6, at 1 P M Temperature 104 degrees F , pulse 100 Respiration 28 Some abdominal tenderness Face flushed, and the pulse small and quick The spleen was palpable The temperature followed the course as shown in the chart until, at 8 P M of the 8th instant, it fell to 98 2 degrees F , after a profuse perspiration The temperature then gradually rose to 103 4 degrees F , the next afternoon, and remitted and rose again to 104 degrees, the second afternoon, and dropped to 94 4 degrees F the third evening, after a profuse perspiration This case had the facies of a typhoid, and there was a suspicion of a renewal of tuberculosis in some form, and yet the behavior of the fever was more like a case of malaria Consequently, at 2 P M , September 10, an examination of the blood revealed hyaline bodies of irregular shape, irregularly pigmented with large, coarse granules It was diagnosed as the quartan form of malaria The subsequent course of the disease demonstrated that it required about seventy two hours for the complete cycle to take place This case teaches the value of a blood examination If the circumstances under which the patient was taken ill had not given rise to a suspicion of malaria, it might not have impressed us a necessity to examine the blood

Case 11 —G W S , age 23, single Sergeant First Illinois V I Had malaria in fall of 1896, ill two weeks Recurrence in February, 1897, continuing until October Is an athlete Was taken with fever September 12, but prior to the fever had been having dysentery for one week Physical state fairly good, but spleen palpable The physician who sent him to the hospital diagnosticated the case as typhoid fever On admission, the temperature was 103 2 degrees F , pulse 102, respirations 20 What appeared to be one rose spot was found on the abdomen Ehrlich's reaction was demonstrated September 17, the temperature ranged from 101 4 degrees F September 19, at 8 A M , it was 99 6 degrees, and at 8 P M , was 100 2 degrees September 19, at 8 A M , it was 98 6 degrees, and has not been above normal since September 19, at 11 A M , the blood revealed the presence of a large endoglobular plasmodium, with coarse pigment granules, very motile, also crescents with sluggishly motile granules

Case 12 —V B , age 30, First Illinois Cavalry Was taken ill at Chickamauga, and the case was diagnosticated as typhoid fever Had frequent bowel movements, abdominal tenderness and was delirious the greater part of the time Was admitted to the hospital September 4 Had a daily exacerbation of temperature at 4 P M , reaching 103 or 104 degrees, No chills September 4 his blood revealed a crescentic body, and on September 14 a small endoglobular body was observed, with sluggish pigment granules Ehrlich's reaction was negative This case did not present the symptoms of typhoid

Cases 13, 14 and 15, gave unimportant histories In case 13 endoglobular plasmodia were found, with very motile granules, in case 14, endoglobular bodies, with sluggish granules, and in case 15, endoglobular and hyaline bodies

CONCLUSIONS

1 The study of these cases has led me to the conclusion that it is the duty of every physician to examine the blood of every patient in which there is an irregular temperature, where the physical signs do not indicate the diagnosis

2 That Ehrlich's test can not be regarded indicative of typhoid fever, measles, or tuberculosis, as it is present in malaria

3 That it is wise to corroborate the fresh blood tests with the stained specimens to prevent the confusion of a vacuole with a hyaline body This point has already been referred to in a previous part of the paper

4 While typhoid fever may run concurrently with malaria, the frequency with which this occurs is not great

5 In some of the irregular forms of the disease we have found that it does not yield readily to quinin

6 In Case 13 there was an idiosyncrasy as to quinin it producing, in small doses, itching of the dody, roaring in the ears, and gastric pains Thirty minim doses of dilute hydrobromic acid were given every four hours for twenty four hours, before the administration of quinin, when ten grain doses could be taken without any discomfort, and it broke up the paroxysms

---

American Public Health Association

Twenty sixth Annual Meeting, held in Ottawa, Ontario, Sept 27-30, 1898

(*Concluded from page 928*)

THURSDAY, SEPTEMBER 29—MORNING SESSION

The association was called to order at 10 o'clock, Dr Benjamin Lee, first vice president in the chair

The secretary reported, on behalf of the executive committee, the resolution of Dr Wingate of Milwaukee, that a special committee of five be appointed for the purpose of drafting a definition of the word "epidemic," with a recommendation that its report be adopted, and it was thereupon adopted Respecting the resolution of Dr Suiter of Herkimer, N Y , to procure the enactment of laws preventing the sale of long rubber tube nursing-bottles, the executive committee reported that it considered such proposed action inexpedient, and recommended that the resolution be not passed, in which the association concurred

Two candidates were proposed for membership and elected by the association

Dr FRANKLIN W WRIGHT of New Haven, Conn , offered a resolution which was referred to the executive committee, creating a special committee of five members of whom the president, secretary and treasurer shall be three, to consider the feasibility of issuing instead of an annual volume of transactions a monthly periodical devoted to sanitary science

Dr HENRY D HOLTON of Brattleboro, Vt , treasurer, presented his annual report, showing a balance of cash on hand of $1 223 03 The report was referred to an auditing committee, vice president Lee naming as sub committee Drs Irving A Watson of Concord, N H , Peter H Bryce of Toronto, Ont , and Dr Franklin W Wright of New Haven, Conn

The first paper on the program for the day was one by Dr MANUEL SEPTIEN of Queretaro, Mexico, entitled

COMPULSORY VACCINATION OUGHT TO BE IMPOSED AS A PARAMOUNT NECESSITY,

and at the request of the writer it was read by Dr Cabara of Fall River, Mass

Dr SEPTIEN regretted the apathy that seemed to prevail on this subject It is just one century, he said, since the immortal Jenner announced to the world the most important discovery registered in the annals of medicine, that which undoubtedly has saved the greatest number of lives Smallpox was in centuries past the most terrible scourge that afflicted the human race It alone accounted for 10 per cent of the total mortality, leaving on the victims it could not carry away the marks of its passage stamped, in an indelible manner, on the whole surface of their bodies But neither the people nor the governments have known how to take advantage of the immense good which vaccine is capable of producing Smallpox ought to have disappeared long ago from all civilized countries, and everybody ought to carry on their arms, as a shield, those everlasting stigmas which vaccination leaves, as a seal printed by the solicitude and paternal care of the enlightened governments, whose lot it is to watch and care for the lives and health of the people, as they are the greatest blessings that man can enjoy here on earth Its practice, however, has been and is still repulsed in the last years of this century of light, even by the peoples most advanced in civilization In England itself, who would believe it ! there are societies, such as the "Anti Vaccination Society," "Peculiar People" and others, who have for their object the opposing of vaccination In this very country, Lower Canada, a great popular movement was started a few years ago, headed by several distinguished medical men, rejecting vaccination The occurrence of several serious cases of vaccinal ulcerations, probably of syphilitic origin, was the cause of this agitation, which had for consequence such a lamentable end Compulsory vaccination could not be carried out from the year 1876, till in 1884 and 1885 such a strong epidemic broke out that in nine months, in the city of Montreal alone, thousands were attacked by smallpox, and causing the death of 3500 persons in nine months Probably this is one of the most notable examples, in these latter years, of the rapid spread of smallpox The ground was already prepared, and the only thing wanting was the sowing of the seed , a Pullman car conductor arriving from Chicago, where he had contracted the disease, was the vehicle of infection Smallpox, with rare exceptions, only attacks those who have not been vaccinated Nor in the most severe epidemics had it ever been seen that the doctors, nurses, or the persons in attendance on the sick had been infected, provided they had been well vaccinated Let us hope that the disease of smallpox will disappear very soon and forever , that which may be considered the most terrible of diseases, because it is the most mortiferous, cruel, and the most loathsome The unfortunate that is not killed by it, is left with the face and the body covered with the most horrible scars , and in many cases it destroys the sight and even the hearing He proposed a petition to the three governments represented in this association to provide more energetic laws than existing ones, making vaccination obligatory and inflicting severe penalties for their evasion

Dr J C SHRADER of Iowa City, Iowa, second vice president of the association, said that in Iowa all children, before admission to the public schools, were required to present marks of vaccination It is held that the State can not pass a law compelling an individual to submit to the operation, as trenching upon the liberty of the person, but the board claims it has the right to establish this rule, and it has been in practice for years

Dr CURTIS of Albany, N Y , said that every member of this Association knows the name of ELISHA HARRIS and remembers his earnest interest in this matter, and that one of his efforts was directed toward obtaining virus from the Jennerian Society with the view of antagonizing the charge as to the danger of inflicting other grievous injury from the use of impure virus

Dr PATTERSON of Winnipeg, Man , doubted whether the courts of any civilized nation will uphold compulsory legislation Vaccination is a disease and it is doubtful whether you have a right to inflict a disease upon an unwilling person School boards, however, can adopt the regulation that children, who do not present evidences of protection against smallpox should not be admitted

Dr GEHRMANN of Chicago insisted that the results of Jennerian-virus can be obtained by modern improved methods—glycerized lymph destroys foreign bacteria and the resultant vesicle is a true "pearl on on the roseleaf "

Dr JONES of Baltimore said that in July last two cases of smallpox were brought into that city from Germany Their companions were vaccinated and developed such bad arms that the tubes used were carefully examined, and in these and many other points large numbers of pus corpuscles were discovered

The report of the committee on "Demography and Vital Statistics in their Sanitary Relation" was then presented by the chairman, Dr CRESSY L WILBUR of Lansing, Mich , Chief of the Division of Vital Statistics of the Department of State

The resolutions embodied in the Committee's report having already been adopted on the recommendation of the executive committee, to whom they had been referred, the committee was by vote continued

Dr JOSE RAMIREZ, general secretary of the Superior Board of Health of the Republic of Mexico then read a paper entitled

OUGHT WE TO REOPEN THE LEPER ASYLUMS?

"Leprosy is still," he said, "scattered throughout the world As its origin is not of a telluric character, we can understand how it invades climates of widely different character It is a disease exclusively confined to man, of a bacterian character, contagious, and one that respects no race whatever " He then alluded to the disappearance and reappearance of the disease in various countries, making the disease serve as a thermometer to indicate the degree of hygiene of different people "These facts lead us to a comforting conclusion That leprosy, an incurable disease, can be suppressed in civilized countries by means that are within the reach of the sanitary authorities An empiric observation of some centuries has perfectly demonstrated the contagious character of leprosy (still denied by some physicians), and the arbitrary measures that up to the middle ages were employed to prevent this fearful contagion proved by their positive results that these observations were correct—that is to say That the isolation of the lepers was the most certain method of preventing the appearance of fresh cases " The disease, the doctor thinks, is not hereditary The long accepted theory that children inherit the disease from contaminated parents has been disproved, and this fact holds out greater hope for the future, besides allowing sanitary precautions to be softened, so that in due time measures may be adopted for preventing contagion It was a fortunate fact that in the greater part of South America leprosy had gradually disappeared "Leprosy has very rarely been found in Canada, although well established cases have been seen In the United States there are a few small foci, which are especially found in Louisiana, Texas, California, Minnesota and Oregon, but the recent annexation of the Sandwich Islands places the nation in an especial condition to at once undertake measures of defence against that immense focus of leprosy which is so well known and is so dangerous

In Mexico we also have leprosy scattered in different States "We, therefore, find that Canada, on account of the British colonies of India, the United States, on account of the foci in its own territory and the recent annexation of the Sandwich Islands, as well as Mexico on account of the numerous foci it contains, are three nations which ought to come to an agreement with the view to taking steps against the propagation and for the establishment of uniform measures of prevention as far as is permitted by the special conditions of each country The character of these measures is a subject that undoubtedly will give rise to a great deal of discussion At the end of the century we can not and ought not to put into practice the ostracism to which lepers were formerly condemned Now, when we know that contagion is something tangible and not a subtle gas or impalpable emanation, now when we have at our disposal means for preventing its propation, now is the time for us to study the most adequate means in accordance with our knowledge, to fight the disease with greater success There can be no doubt that these humane sentiments inspired the governments that convened the international conference for the study of leprosy, which met in Berlin during the year 1897 This conference, attended by the most competent specialists of the world, and starting from the principle of the incurable character of leprosy, passed resolutions directed to the prevention of the propagation of the disease."

The deductions are as follows

1 In countries where leprosy forms foci, or has great extension, isolation furnishes the best means of preventing the spread of the disease

2 The system of obligatory notification, observation and isolation, as carried out in Norway, is recommended to all nations with local self government and a sufficient number of physicians

3 It must be left to the administrative authorities after consultation with the medical authorities, to take such special measures as are applicable to the special social conditions of the districts

Dr HENRY M BRACKEN of Minneapolis, secretary and executive officer of the State Board of Health of Minnesota, presented and read a paper on the same subject entitled

LEPROSY IN MINNESOTA AND THE NORTHWEST

He questioned the accuracy of the statements in Allbert's System of Medicine respecting the Norwegian leper of Minnesota, Wisconsin and Dakota, and said we have knowledge of fifty one lepers having resided in Minnesota, seventeen of whom had died before 1890 Twenty one is probably the highest number of lepers known to have been living in this State in any one year (1893) At present thirteen are known to be living there Dr Bracken drew special attention to a few facts emphasized by his tables and records

1 The impression that leprous immigrants from the Scandinavian peninsula are all from Norway is a wrong one Five of eleven recorded in 1897–8 were from Sweden

2 The feeling that we can quarantine against lepers by watching immigrants is an unsafe one The family history of all immigrants from a country where leprosy prevails should be secured before they are allowed to embark for America, and no member of a leprous family should be permitted to land upon our shores

3 It appears that the conditions antagonistic to the spread of leprosy are also opposed to sterility, as borne out by the families of our lepers who have children, as shown by the following numbers five, five, six, six, four, six, four, five, eight

4 It is possible for leprosy to die out in certain favored sections, as Minnesota, without segregation, provided the importation of lepers is discontinued

5 Even in Minnesota one has but to visit lepers to feel that segregation should be insisted upon in all cases Entering a filthy house and seeing a leprous mother, careless in her habits, it is evident the children are not safe

6 Segregation in single States is not practicable, since it would only drive lepers from States enforcing it to those not doing so

7 A federal home should be provided for these unfortunates where they could be cared for more economically and satisfactorily than through any State's provisions

8 In spite of all precautions there will be some leprous individuals in this part of the world for many years to come

9 The Scandinavian peninsula does not furnish all the leprous individuals found in the United States

The discussion on the papers of Drs Ramierez and Bracken was very animated Dr Henry B Horlbeck, health officer of Charleston, S C , urged the establishment of a Federal leper home on one of the islands on the southern Atlantic coast of the United States

Dr WILKINSON of New Orleans, said that the State of Louisiana had already rented a tract of land in that State and established a leper home, admission to which was not made compulsory, but where they went willingly They cultivated the land, so that the home was almost self supporting The leper wants occupation He did not think the Atlantic coast islands the preferable site on account of the gales to which they were subject.

M W BOARDMAN of Ottawa of the Department of Agriculture, described the Dominion Government's Lazaretto at Tracadie, N B , where he said there were a year ago twenty inmates, sixteen of these males, the youngest eleven and the oldest sixty one Four are in the early stage, ten were advanced, and six far toward the end There were nine deaths in the year, all having been enfeebled by *grippe* Eight new cases have been admitted, four from Manitoba All, including the Icelandic parties, seem surprisingly contented There is seldom any difficulty in the absence of a law enforcing segregation in removing those affected When a man is declared leprous by the inspector of leprosy, his neighbors and those giving employment shun him, and he is glad to avail himself of the comforts of the leper's home The Lazaretto at Tracadie is fulfilling its object, that of segregation, in the most satisfactory manner

Dr Lee of Philadelphia said that of the two plans, isolation recommended by the author of the first paper, and segregation by the second, he was decidedly of the opinion that segregation was the proper course His opinion was concurred in by Dr Burroughs of Abbeville, N C , Dr Gibson of Iowa and Dr Patterson of Manitoba

Dr Jones of Baltimore instanced the single leper, who is so great a trouble and expense to the health office of that city, that it illustrates the necessity for the national government to establish a home where similar cases can be segregated

Dr Durgin of Boston said that a leper is so dreaded, and the facilities for their care so lacking, that cases are hidden away as long as possible He has one case who requires a special nurse and all the paraphernalia of a hospital, who ought properly to be in some home

Dr Horlbeck of Charleston, S C , offered a resolution, which was referred to the executive committee, that the American Public Health Association call the attention of the government to the presence of leprosy in the country, and urge the necessity of establishing a home where sufferers from this disease can be segregated and given proper care

Mr Crosby Gray, health officer of Pittsburg, Pa , related the case of a native Pittsburger, who contracted leprosy in Para, Brazil, ten years ago, and finally returned to his home sick He entered a hospital, where the case was diagnosed as leprosy and he was surreptitiously removed He is now in a separate building in the hospital grounds, under the care of a nurse at two and a half dollars a day, making his maintenance rather an expensive luxury

Dr George H Rohe, former health officer of Baltimore, Md , deprecated the sanitary shrieking and hysterics excited by this disease, and said he would just as soon treat a case of it in a general hospital as any other In fact, it is less dangerous than syphilis Nevertheless, he believed it would be wise to have a home established where the leprous could be comfortably domiciled and properly cared for

Dr Breña of Zacatecas, Mexico, said if this resolution accomplishes its purpose, it will alone be sufficient to justify this meeting He would rather die of diphtheria than live neglected like a leper

The report of the committee on Sanitation, with Special Reference to Drainage, Plumbing and Ventilation of Public and Private Buildings, was presented by the chairman, Mr J W Hughes of Montreal

Thursday, September 29—Afternoon Session

The Advisory Council convened at 2 p m at the Parliament Buildings Thirty three members were present, representing as many different States and Provinces—twenty two American, four Canadian and seven Mexican—the President of the Association, Prof Charles A Lindsley, being ex officio chairman The council proceeded to nominate officers for the ensuing year and select the place of the twenty seventh annual meeting in 1899 Invitations to hold the meeting were presented from Minneapolis, Minn, Asheville, N C , New Orleans, La , and Chicago, Ill The fact that this was the third time the association had been invited to Minneapolis determined the choice of the council

The afternoon session of the association was called to order at 3 p m , the first vice president, Dr Benjamin Lee of Philadelphia in the chair

Mr J W Hughes of Montreal read the first paper, entitled

THE INTERCEPTING TRAP IN PRIVATE SEWERS,

supplemental to his committee report, and which adjournment for luncheon prevented being read therewith He unhesitatingly condemns the fitting of the intercepting trap in private sewers 'Minute investigation has "shown that when a main intercepting trap was used that it not only modified the speed and partly obstructed the flow of sewage, but it prevented any of the air carried down by the soil and other waste water pipes from discharging into the street sewer, where its areating functions are so necessary to commence the purification of the sewage in the drains and assisting in preventing sewer gases generating in the sewers " It has also been shown "that when the main intercepting trap is omitted there is a superior and self cleansing flow of sewage, and that large volumes of air pass forward to the street sewer, creating a healthy atmosphere and circulation of air down the soil pipe, through which the fluid is passing, and up other soil pipes that are at the time standing idle " Mr Hughes said that his observation had led him to believe that in houses in which there was an absence of sewer pipes having obstructing traps there was freedom from odors and diseases that could be traced to sewer gas poisoning, while on the other hand those cities which had adopted the principle of interception traps were often quite the reverse, and of disease a great deal was found among the inhabitants who happened to live in the modern built houses, where the obstruction system had been installed , "and this, in spite of the fact that the same towns often spend large sums of money in flushing the drains and artificially ventilating the street sewers, a thing which is never necessary if the sewers are laid down properly and the right unobstructed system is adopted

Dr S H Durgin, health officer of Boston, Mass , contended that bad gas fittings are more dangerous to health than bad plumbing He said that better regulations are needed to insure the proper fittings to prevent the escape of illuminating gas He claimed that there is no scientific basis for considering sewer gas an active poison or a serious source of danger to human life On the other hand, he said illuminating gas contains a most active and deadly poison No deaths are reported as resulting from sewer gas poison, but many are reported as caused by illuminating gas In the last five years, 169 deaths from it have occurred in Boston He said the medical profession believed that many deaths were caused by slow poison from illuminating gas, but they were not so entered in the public records Health officers, he insisted, should pay as much attention and teach the danger from coal and illuminating gases circulating in the atmosphere of houses as they do the danger of the escape of sewer gas In 1897 an act of the legislature of Massachusetts was obtained which requires all persons who desire to engage in or work in the business of gas fitting in the city of Boston, either as an employer or journeyman, to be examined by a board established for that purpose, and if found to be competent to receive a license as a master or journeyman gas fitter The act authorized the board of health and building commissioner to make and enforce regulations for all materials used and work performed in gas piping and gas fitting, provided for the appointment of a corps of inspectors, who examine for approval all new work in construction and repairs, authorizes the board of health to inspect the gas fixtures and appliances in any building, and to make such requirements relating thereto as it deems the public health requires, and the owner of such building must comply with such requirements

As a result of an investigation, it was found that 89 per cent of Boston's houses showed from two to eleven leaks in each house Out of 153 houses examined 137 had defective pipes, and only 16 were found absolutely free from defects

The discussion was further participated in by Dr Chapin of Rhode Island, who inquired if any deaths were positively known to be caused by leaking gas pipes, by Dr Schwartz, secretary of the State Board of Health of Rhode Island, by Medical Director Gihon, U S N , who asked Mr Hughes if he believed that gas leakage could ever be attributed to fire holes in old gas pipes concealed between floors and ceilings or inside walls to which Mr Hughes replied that in thirty years' experience he had never known an instance of perforated pipes, but that leakage was always from imperfect connections, by Dr Wright of Connecticut, by Dr Woodward of Washington, D C , and by Dr Mitchell of New Jersey

Dr F X Valade, chief analyst, of Ottawa, Ont , read a paper on

THE ADMINISTRATION OF THE ADULTERATION ACT IN CANADA

He reviewed the Dominion act in regard to adulterated foods, etc , and said that the analytical department is now in good working order Each district has its analyst and the analysts are supplied with samples of food products by food inspectors The samples are analyzed and the results with the names of the persons from whom they are obtained announced He spoke of the adulterations of milk and said that grave results followed the adulteration of this staple article of food Lead poisoning results, he said, from the use of lead in the manufacture of house utensils, and in tins used to preserve foods Rouge is often adulterated with lead, and as it is in a condition to be easily assimilated, lead palsy results from the use of the rouge

He considered the combination rubber and tin stoppers used in bottles containing carbonated waters most dangerous The most dangerous and shameful adulterations are the following Coffee is adulterated by the process of washing, coloring and drying off in centrifugal machines with sawdust, the furrows of the berries become filled with wood powder, making them a fine white Weak milk is richly colored with annatto, saffron, turmeric and marigold flowers Saffron is adulterated with coal tar Coal tar is adulterated with 75 per cent of sodium chlorid, and here the chain ends, for salt is too cheap to require adulteration Cayenne is sometimes too hot, red ochre, venetian red or brick dust corrects that, and a little salt to make it tasty completes the trick Honey and cocoa are adulterated, oleomargarin is palmed off after being colored with azo dyes and orange red Musk deer sacs are often opened and filled with stones, bits of metal and brown earth

Dr Juan Breña of Zacatecas, Mexico, presented "Rough Notes on the Etiology of Typhus Fever" It was an admirable and exhaustive inquiry into the subject, emphasizing the value of sanitary considerations in preventing the development and spread of this disease As the individual who cultivates cleanliness of person and dress, tranquillity of mind and, in a word, devotion to the Goddess Hygeia, bears within himself a shield which protects him to a certain extent from infection, so do collective bodies of individuals who enjoy air, light, abundance of water, a fair amount of sunshine, good drainage etc, represent ground but little fertile for the development of typhus It would be well if we could accept the theory which attributes the generation of that fever which from time to time plunges us, especially in Mexico, into mourning to the stagnation of organic matter in a state of putrefaction or to that train of misfortunes following on poverty"

The report of the committee on

CAR SANITATION

was presented by the chairman, Prof S H Woodbridge of Boston, Mass, which was read by Dr J N Hurty of Indiana Professor Woodbridge's report attracted the closest attention of the members for its admirable presentation of the subject of heating and ventilation of railway cars, and was an unusually acceptable communication, as the information given was in effect the record of a victory won by this association through this committee after a number of years' work, in inducing several of the big railroads in the United States to adopt sanitary arrangements in the running of their cars Letters from various railroad officials were given, stating their intention to reconstruct all their cars so that cleanliness would be a most important feature The author referred to sanitary precautions already adopted by the railroads in Indiana, where the interiors are so constructed as to prevent as much as possible dust lying in the spaces in the cars He outlined two systems of ventilation in use in two United States railroads In the Pennsylvania Railway system of ventilation of cars, air is drawn from outside the car through ducts, is then passed over steam radiators between the floors and then introduced into the car under the seats This avoids warming over and over the dead air in the car The bad air goes out through openings in the roof The Big Four Railway system of car ventilation is to draw out the bad air from near the floor through ducts between windows in the walls of the car Pure air is introduced from outside by ducts with filters at the ends of the coaches This pure air is warmed as it enters by being passed over steam pipes The Big Four railway officially promises to hereafter construct all passenger cars according to the latest sanitary requirements The thorough system of cleaning and disinfection of cars by the Big Four was warmly approved by the writer

Dr Gregorio Mendizabal of the City of Mexico read a paper "On Diseases of the Skin and of the Hairy Scalp, Which are Commonly Transmitted by Contagion at Schools, Ways of Preventing It" After paying tribute to the benefits that mankind has already received through following the wise councils of hygiene, the author suggested, respecting the prevention of communicable dermatosis, that medical inspectors for schools should be appointed and children be required to furnish clean bills of health before they are admitted to schools Inspection should be extended to private schools The parents of poorer children should be furnished with remedies to cure their diseased children The diseases he had found most frequently are psoriasis, scurf, tricophicies, fabus all shown to be transmissible and repugnant and dirty, although not fatal

The remainder of the afternoon and up to a late hour was entirely occupied with the subject of "Disinfection and Disinfectants," beginning with a preliminary report of the Committee on Disinfectants by its chairman, Prof Franklin C Robinson of Bowdoin College, Brunswick, Me, followed by papers on "Methods of Testing Disinfectants," by Dr Wyatt Johnson, Montreal, Dr F G Novy, Lansing, Mich, Dr Hibbard W Hill, Boston, Mass "Methods of Using Disinfectants" *In Cities*, Dr Adolph Ghermann, Chicago, *In Hospitals*, Dr J J McKenzie, Toronto, Ont Dr Chas D Smith, Portland, Me, *In Quarantine Work*, Dr F Montizambert, General Superintendent of Quarantine of the Dominion of Canada

The lateness of the time prevented discussion of this most interesting and valuable group of papers, which fitly concluded one of the most successful day's work in the history of the association

A resolution offered to create a special committee to secure co operation in bacteriologic investigations in the three countries represented in the association was referred to the executive committee

Fourth Day—Friday, Sept 30, 1898

Morning Session, 10 a m

The president, Prof Charles A Lindsley in the chair

After the final announcement by the chairman of the local committee of arrangements, Dr John Sweetland of Ottawa, of post adjournment courtesies tendered by the Minister of Agriculture of the Dominion Government, the secretary, Dr Probst, presented the final report of the executive committee, recommending

1 The adoption of Dr Horlbeck's resolution to urge the establishment by the National government of a leper house

2 The appointment of a special committee, as suggested by Dr Wyatt Johnson of Montreal, for co operation in bacteriologic investigation by colleges, individuals and committees engaged in this work

3 The continuance of the committee on Public Health Legislation, of which Dr Henry P Wolcott of Cambridge, president of the State Board of Health of Massachusetts, is chairman, that it be urged and required to make every possible effort to promote the purpose for which it was created, and that the American Public Health Association hereby reaffirms its opinions of the advisability and necessity for the establishment of a National Board or Bureau of Health in the United States

4 The adoption of the resolution of Dr Wright proposing a special committee of five, consisting of the president, secretary, treasurer and two others to consider the advisability of substituting for the annual volume of transactions a monthly or other periodical devoted to sanitary matters, in all which the association by vote concurred

On motion of Dr Suiter of Herkimer, N Y, the association reconsidered its action of yesterday, declaring it inexpedient to adopt the resolution offered by him advising State, municipal and town authorities to enact laws interdicting the sale of long rubber tube nursing bottles, and upon his modification of his resolution making it expressive of the opinion of the association that the long rubber tube nursing bottle was a positive menace to the health and the cause of much mortality of infants, it was unanimously adopted It was explained on the part of the executive committee that its former action in declining to recommend the effort to obtain legislation was because of the belief of its members that no educated physician would permit, and no intelligent and competent mother use, one of these bottles, which the veriest tyro in sanitation could not but condemn, but as its action has been misunderstood, as was shown by conspicuous head lines in the newspapers announcing that "the association had shut down on the effort to abolish the rubber tube nursing bottle," and that "the rubber tube bottle had gained a victory over its opponents," and lest these assertions, if uncontradicted, might be taken advantage of for advertising purposes by the unscrupulous makers of these bottles, it was considered proper that the association should assert, notwithstanding the elementary and self evident nature of the proposition its, unanimous condemnation of their use As an evidence of the universality of this use, Dr Wende, the health officer of Buffalo, who has succeeded in making their sale impossible or punishable in that city, exhibited three long tube bottles which he had bought in the first three drug stores in Ottawa at which he had applied for them

Three additional applicants for membership were reported by the executive committee and elected

Medical Director Gihon, U S N, read a letter he had just received from Dr Jesus E Monjaras, president of the Council of Health of San Louis Potosi, regretting his enforced non attendance at the meeting by reason of a recent domestic bereavement

On motion of Dr Gihon, the secretary was directed to telegraph on the part of the association to Dr James F Hibbard [illegible] one of [illegible] zealous and most [illegible] regret that he had been prevented by illness from being present as he had invariably been at previous meetings

On motion of Dr **Durgin** of Boston, Mr Mitchell of New Jersey was appointed to draft a suitable memorial expressive of the regret of the association at the recent death of Dr **J Berrien Lindsley** of Nashville, Tenn , an original member and the long time treasurer of this association, and to place on record in its Transactions its appreciation of his personal character and disinterested and zealous service in the work of this association and the cause of sanitation

Dr **Irving A Watson** of Concord, N H , chairman of the auditing committee reported that careful examination of the accounts of the treasurer showed that they were correct in every respect

Mr **Crosby Gray** of Pittsburg, Pa , secretary of the Advisory Committee, reported the following nominations for officers of the association for the year 1898 '99

For President Dr **George H Rohé**, of Baltimore,, Md

For Vice President Dr **Jesus E Monjaras** of San Louis Potosi, Mexico

For Secretary Dr **Charles O Probst** of Columbus, Ohio

For Treasurer Dr **Henry D Holton** of Brattleboro, Vt

For Elective Members of the Executive Committee (for two years) Dr **H M Bracken**, of Minneapolis, Minn , Dr **Irving A Watson** of Concord, N H , Dr **Franklin W Wright** of New Haven, Conn (To fill a vacancy for one year) Dr **Gregorio Medizabal** of the City of Mexico, Mexico

The Advisory Council recommended that the twenty seventh annual meeting shall be held at Minneapolis, Minn All which was by vote of the Association unanimously adopted and the officers unanimously elected The president then announced the names of chairmen and members of committees, of which there are twenty one

Papers on "The Diptera from a Hygienic Point of View," by Dr Ramon Ramirez of Mexico, D F , and on "The Spread of Typhoid and Dysenteric Diseases by Flies," by Dr M A Veeder of Lyons, N Y , were then read, and discussed by Dr Gardner T Schwartz of Providence, R I , and Dr J N Hurty of Indianapolis, Ind , who related an instance within his own experience of the spread of dysentery at Tipton, Ind , from a patient whose injecta, it was discovered on subsequent investigation, had been thrown into the back yard, and where the only possible hypothesis as to the spread of the dysentery was that it had been propagated by flies, which were then especially numerous The views of the authors of the papers, Drs Ramirez and Veeder, were quite in accord with the reputed opinion of the military committee of investigation appointed by our ex president, Surgeon General Sternberg, U S A , Majors Vaughan, Shakespeare and Reed, who are alleged to have declared flies largely responsible for the distribution of typhoid germs in our military camps

The following reports of special committees were then presented and read Report of the committee on Transportation of Diseased Tissues by Mail, presented by the chairman, Dr E P Lachapelle, president Provincial Board of Health, P Q , report of the committee to consider and report upon some Method of International Arrangement for Protection against the Transmission of Infectious Diseases, presented by Dr Frederick Montizambert, chairman, general superintendent of quarantine of the Dominion of Canada , report of the committee on Animal Diseases and Animal Food, presented by D E Salmon, D V M., chairman, chief of Bureau of Animal Industry, Department of Agriculture, Washington, D C , report of the committee on The Duties and Responsibilities of the Healthy Man for His Own and Others' Health, presented by the chairman, Dr Charles N Hewitt, Red Wing, Minn , report of the committee on public health legislation, presented on the part of the chairman by Dr Henry P Wolcott, president of the State Board of Health of Massachusetts, by Dr U O B Wingate, health officer of Milwaukee, Wis

The following papers were then presented "An Epidemic of Diphtheria traced to an Infected Milk Supply" by Dr Benjamin Lee, health officer of Philadelphia, Pa , "Preventive Antirabic Inoculation Service in Mexico," by Dr Eduardo Licéaga, president Superior Board of Health, City of Mexico, "Report of Some of the Most Important Papers Presented at the Fourth Congress of Tuberculosis, held in Paris, July 27 to Aug 4, 1898," by Dr E A de Schweinitz, director Biochemic Laboratory, Bureau of Animal Industry, Washington, D C , "The Sanitary Treatment of Inebriates," by Dr A M Rosebrugh, secretary Prisoners' Aid Association, Toronto, Ont , "Garbage Reduction by Steam," by Dr M A Veeder, Lyons, N Y , and Mr J L Richards, sanitary engineer, Elizabeth, N J , the last eliciting discussion by Dr de Schweinitz of Washington, D C Dr Probst of Columbus, Ohio, and Mr Rudolph Hering, C E of New York City

The customary resolutions of thanks were then adopted for courtesies received from the Dominion Government, especially the Hon Sidney Fisher, minister of agriculture, the mayor, municipal officers and citizens of Ottawa, the indefatigable chairman, Dr John Sweetland, and his associates on the local committee of arrangements, the ladies of Ottawa, the proprietor of the Russell House, the railroad officials and the members of the press

The two senior ex presidents, Medical Director Gihon, U S N , and Dr Durgin of Boston, were then appointed to conduct the president elect, Dr George H Rohé of Baltimore, to the chair, and after appropriate remarks by himself and the retiring president the latter declared the Association adjourned to meet at Minneapolis at such time in November, 1899, as the executive committee may appoint, thus concluding one more of the successful and satisfactory assemblies of this flourishing body The majority of the members remained after the formal adjournment to attend a garden party at the Experimental Farm tendered by the minister of agriculture, Hon Sidney Fisher, and voluntarily added another day to their sojourn in this attractive and hospital capital of the Dominion, where besides the courtesies of the government and municipal authorities, they were treated to a week of the most delightful weather conceivable The unparalleled invigorating climate determined the American and Mexican members, who contemplate attending the Third Pan American Medical Congress at Caracas, Venezuela, to insist that Ottawa shall be the site of the Fourth

Chicago Medical Society

At the clinical meeting, October 2, in the absence of the president, Dr **Arthur D Bevan**, Dr **George W Webster** presided

Dr **Homer M Thomas** reported a very interesting and instructive case of aortic aneurysm, and exhibited the patient

Dr **Webster** exhibited, in connection with Dr Thomas' case, a pathologic specimen from a similar case of aortic aneurysm

Dr **I A Abt** described an interesting case of rachitis that came under his observation, and exhibited photographs and skiagraphs of the case

Dr **Carl Beck** exhibited a little girl, 14 years of age, upon whom he had operated, showing the results of a rhino blepharoplasty, the patient having undergone eight operations in all The second case was one of partial rhinoplasty The third was another nose case, but in which the destructive process was very extensive, due to erysipelas The fourth was a case of arthroplasty, the ankylosis of the joint being due to tuberculosis

Dr **H W Davenport** reported an interesting case of artificial self retaining maxillary arch and floating palate in a boy of 10 or 12 years of age Five surgical operations had been previously performed by different surgeons for the closure of the cleft without success The boy removes and replaces very easily and dexterously the artificial palate

Dr **O T Stein** reported a case of caries of the skull due to syphilitic infection

Dr **C L Lockwood** presented a case which beautifully illustrated the union of old fracture by percussion irritation He noticed a marked improvement at the end of two days from this method of treatment, and in about two weeks there was almost complete union

Dr **Charles E Paddock** reported a case of placenta succenturiata

Dr **George W Johnson** detailed five cases of congenital with acquired hernia

Dr **Edward J Brougham** reported a case of carbolic acid gangrene The patient sustained a slight injury with a knife at the base of the phalanx and fifth metacarpal, and three days after the application of 3 per cent carbolic acid gangrene occurred

Washington Obstetrical and Gynecological Society

The 285th meeting of this society was held on the 7th instant The President, Dr **T C Smith**, read his annual address, entitled

WHAT HAVE YOU TO OFFER THAT IS BETTER?—A QUESTION FOR CRITICS

He referred to the attitude of the conservative writers, both in medicine and surgery, and drew attention to the injury they did by criticising unfavorably all operative procedures of others, thereby tending to thwart medical process He showed how, in early medical history, these conservatives and critics had assailed the work of Ambrose Paré, Genner, McDowell and Battey He extolled the language of Joseph Price, who said "the aim and effort should always be to bring the patient into as normal a condition as possible, and make very improbable the necessity for a repeated operation" , and again, "complete work offers the best chance for complete recovery in about all cases " He admitted that some surgical operations had been done which should have been left undone, so far as the existing state of affairs was concerned, but went on to say that "even these, in the early state of the science, had been beneficial in teaching lessons from which the modern science has been developed " He referred to hysterectomy for fibroids and its early mortality, and compared it with the present death-rate He referred particularly to the unwise criticisms of our co associate, Dr Joseph Taber Johnson, during his early work and asked of the critics what they had to offer as a substitute that is better than the treatment pursued by the surgeons He referred to the present status of the treatment of unavoidable abortions, tubal diseases and extra uterine pregnancy, and showed how early adverse criticism had been largely responsible in delaying the acceptance of the modern and successful treatment of these conditions In conclusion he said "The surgeon who performs an operation for relief of disease is entitled to just and fair treatment in the matter of criticism of his work I believe he never removes more than he thinks the case demands, and that he is a better judge of the necessities of the case than the critic who sits at his desk and shoots his arrows, regardless of the harm he may do " He said "The critic is an obstacle in the way of progress, and while advancing nothing himself, does not want any one else to do that which advances scientific medicine and surgery In medicine and surgery progress has the right of way, and he who would impede its advance will be inevitably side tracked Permit me then to say to those who find pleasure in disparaging the work of others by unfriendly criticism, when you have concluded your strictures on operations devised by faithful men, be kind *enough to tell us, in the way of treatment, what you have to* offer that is better "

At the conclusion of his remarks a vote of thanks was tendered him, both for his paper and the faithful and efficient manner in which he had conducted the office of president during the past year

Denver and Arapahoe Medical Society

At the meeting held October 11, Dr Wm P Munn read a paper on

THE CHOICE OF ROUTE IN OPERATION OF THE BLADDER

He said in part The bladder may be reached for purposes of surgical treatment by the following routes 1 By the catheter, sound, cystoscope or lithotrite through the urethra, both in the male and female 2 In the female, by a cutting operation through the anterior wall of the vagina 3 In the male by aspiration and incision through the rectum 4 In both sexes by aspiration or incision through the anterior abdominal wall above or posterior to pubic bone 5 In both sexes, by intraperitoneal incision or aspiration or by urethral catheterization when a prior operative procedure has laid open the abdominal cavity 6 In the male, by perineal incision which may be directly into the bladder or by prior opening into the urethra After a careful theoretic consideration of the value of the different routes coupled with a larger clinical experience, the author has arrived at the conclusions that the perineal operation gives ready access and sufficient opportunity for opportunity for operative attack in the following cases 1 Foreign bodies in the fairly normal bladder, best, surest, safest route The incision is at the most dependent portion of the bladder, and therefore, nearest to the usual location of stone or any other foreign body, it leaves an open avenue for drainage, the opening is made with the least possible disturbance of the bladder structures, and, lastly, the wound heals with rapidity, leaving no annoying sequelæ 2 In a moderate percentage of instances of enlarged prostate 3 Single polypus 4 For single exploratory incision no other route is justifiable 5 The prolonged drainage 6 In dealing with large growths the perineal opening should precede and be used in conjunction with the suprapubic opening to facilitate the manipulations and to permit of proper drainage As a formal conclusion it may be stated that the suprapubic operation is not often required as a primary surgical procedure, but that its greatest usefulness is when it is resorted to either as a secondary measure or in conjunction with the perineal operation

Dr C A Powers, in discussing the paper expressed himself in favor of the crushing operation, especially in children He praised highly the procedure of distending the bladder with air, especially in cases where the bladder is greatly contracted,

Dr, Munn, in his concluding remarks, gave the statistics in his own practice 47 perineal sections with 3 deaths, 9 supra pubic sections with 3 deaths

Dr Wm C Mitchell read a paper on "The Gonococcus," which was discussed by Drs Munn, Stover, Whitney and Axtell

PRACTICAL NOTES

Lymphatic Apparatus of the Uterus —Peisser has found the lymphatic glands affected in more than 50 per cent of the cases of carcinoma colli uteri he has examined This propagation occurs early, while the carcinoma is still operable and the lig lata are supposed to be still "free " The regional glands should therefore be removed with the neoplasm, which can not be accomplished per vaginam, and renders the abdominal route imperative He has established by means of injections that the glandulæ hypogastricæ and sacralæ are the first stations of the collum uteri system —*Munich Med Woch* , from *Ztft f Geb u Gyn* , xxxix, 2

Protargol in Ophthalmia —Darier considers protargol very valuable in acute catarrhal conjunctivitis, which it cures in three days, and also in purulent gonococcus, which it cures in from eight to twenty days He touches the inflamed suface with a solution varying from 20 to 50 per cent, according to the severity of the case In a collyrium the dose is only 5 per cent Protargol (combination of silver with a protein base) is not irritating nor caustic like nitrate of silver Furst has protected infants from a maternal gonorrhea with a 10 per cent solution without the slightest irritation to the eyes —*Bulletin de l'Acad de Méd* , August 23

The Abuse of Cocain —Scheppegrell (*Med News*, October 1), writing on "The Abuse and Dangers of Cocain," attributed the establishment of the cocain habit, in the majority of the cases, to the prescription of the physician, and believes that it should never be prescribed for the patient's use He has found a peculiar phase evident in New Orleans in the contriction of the cocain habit by the negroes, a few crystals of the drug being snuffed into the nostrils for its exhilarating effects, physical and mental wrecks resulting He believes the druggist should be compelled to restrict the sale of this as well as of other toxic drugs to the prescription of the physician,

Pernicious Anemia of the Puerperium —Vinay considers every remedy injurious except arsenic, and to avoid the almost inevitable gastric and local disturbances, he prefers the rectal to the gastric or hypodermic method of administration Large injections produce intolerance, and he never exceeds five grams His formula is four grams Fowler's solution to fifty six grams aq dest The injections are made morning and evening for four days, and then three times a day In very severe cases he increases the proportion of arsenic five grams to forty five grams aq dest —*Médecine Moderne*, No 54

Hot Air as a Hemostatic —The jet of hot air from a Hollander apparatus directed upon the bleeding surface of a kidney, liver or severed blood vessel, will arrest the hemorrhage by the formation of an eschar commencing around the edges and gradually spreading over the entire surface, mechanically checking the flow, in experiments on animals, and Schneider concludes that it would be equally effective on man The heat is only 39 degrees at 5 mm from the apparatus, and hence is not sufficient to injure the organ He found steam less effective, and less convenient, for several reasons, masking the field of operation, etc —*Semaine Méd* , August 3

Progressive Pernicious Anemia —E Grawitz relates a number of observations in the *Berlin Klin Woch* , No 33, which demonstrate the efficacy of dietetic treatment with an early diagnosis In some cases repose in bed is the first requirement Loss of appetite is restored by treating the usual constipated condition, disturbances in the gastric secretions are treated by stomachica of all kinds and a mixed diet Treatment in a sanitarium is often indispensable He considers iron absolutely contra indicated in the first stages of treatment Arsenic in cautiously progressive doses, and quinin, are much more appropriate The effect of transfusion of blood is merely temporary —*Munich Med Woch*

Surgical Treatment of Pericarditis —Brentano has reported five patients treated by opening up the pericardium, with resection of the ribs, which he considers necessary, as a single puncture will scarcely ever allow the evacuation of the entire amount of pus, and incision without the preliminary resection is much more dangerous and less effective Pericardiotomy only promises success in acute cases Two cases of suppurated pericarditis ended in death, two cases of long existing serofibrinous pericarditis were only temporarily improved, but the fifth case was cured—a 10 year old girl—pericarditis consecutive to rheumatic endocarditis —*Deutsche Med Woch*, August 11

A Valuable Disinfectant —The disinfectant recommended by Kronig and Paul, discovered in the course of their painstaking tests of various disinfectants by the light of the new physico chemic theories of solutions and electrolytic dissociations, is a mixture of potassium permanganate and hydrochloric acid This solution kills the most resistant spores from extremely virulent anthrax bacilli in a few minutes, while it is cheap, non toxic, convenient and fully equal to a 5 per cent solution of sublimate They ascribe its remarkable microbicidal power to its extremely active ions As a disinfectant for the hands, for instance, they recommend the formula 45 c c of pure hydrochloric acid, dilute with 1600 c c of water, add 500 c c of a 5 per cent solution of potassium permanganate The solution also stains the skin, but the latter stain is easily removed, with a 1 3 per cent solution of oxalic acid —*Ann de la Soc Méd Chir de Liège*, June, from *Ztchft f Hyg*, xxv

Suprapubic Cystostomy for Prostatism —Poncet has performed this operation 114 times, with 27 deaths, since he proposed it in 1889 The prognosis depends almost entirely upon the condition of the kidneys and other organs It differs from cystotomy, as the lips of the bladder are sutured to the edges of the incised abdominal walls to form a permanent meatus It is especially adapted to incurable urinary affections for which he urges its general adoption, recommending an early operation It has again and again restored elderly men to health, when apparently in the last stages of urinary intoxication A typic observation is that of a blacksmith cystostomized six years ago, who retains his urine three to five hours and emits it in a stream 30 to 40 centimenters in length, through the hypogastric meatus Natural miction has never been re established, as the prostate has remained enormous, fibrous and knobby Another case, 87 years of age, in acute urinary intoxication with temperature at 40 degrees C continuous delirium, etc, was relieved at once with cystostomy, and a couple of months later natural miction was restored, the patient is now in good health, a year later The artificial meatus becomes a fibro elastic ring, often quite thick, and lined with mucosa throughout Out of 34 patients who have retained their new meatus, there is continence in 14 cases, partial continence in 7 and incontinence in 13 —*Bulletin de l'Acad de Méd*, August 8

Eighty Nine Symphysiotomies —Dr Pinard of the Baudelocque Clinic at Paris has issued a report concerning seven operations by symphysiotomy in 1897, making a grand total of eighty nine such operations performed in that clinic during the six years, 1892–97 Six of the cases were examples of rickety, flattened pelves, while the remaining case was one of a Naegelé oblique pelvis Of the mothers, two were primiparæ and five multiparæ, of the former one died from sepsis and acute albuminuria, the latter complication being present upon her admission to the clinic All the children were born alive, three being delivered by forceps and four by version In one patient the operation was performed for the second time, her second pregnancy having been terminated by symphysiotomy in 1892 At the first operation a tear occurred through the anterior vaginal wall into the operation wound, and at the second operation a similar accident happened in spite of every care being taken to prevent it The urethra and bladder, however, escaped injury and the wound healed well In the event of this patient again becoming pregnant Pinard considers that Cæsarean section would be indicated on account of the cicatricial tissue present in the anterior vaginal wall That symphysiotomy may produce some permanent enlargement of the pelvis, seems to be shown by the fact that four of the patients delivered spontaneously during the year had previously had symphysiotomy performed upon them, the report is of interest as enabling us to watch the progress of the operation Pinard has no hesitation in saying that in any future history of symphysiotomy a very important place will have to be assigned to the work done at his clinic —London *Lancet*

Extirpation of the Rectum —For inflammatory strictures this is not proving as successful as anticipated A study of 69 cases in the *Presse Méd* of September 14, shows that 10 died from the operation, 4 in the course of the year, from pneumonia, pulmonary tuberculosis, prolonged suppuration or puerperal infection from the sacral fistula The stricture recurred in 12 out of 24 cases followed over a year Incontinence was almost the rule, except in very constipated patients The suppuration was almost certain to persist, and with the Kraske operation the chances were in favor of a sacral fistula (7 in 15 cases) A number of patients have incontinence whenever the matters are soft, and obstruction when they are hard, with a constant flow of pus The article concludes with a plea for colotomy, and an artificial anus, easily kept clean and the only chance for the inflamed rectum to heal spontaneously, when natural conditions can be restored "When dilatation, combined with antiseptic lavages of the rectum does not produce the desired effect, temporary or permanent colotomy is the best palliative Extirpation has proved impotent to cure and should no longer rank as an approved radical method" "Even in tuberculous lesions the suppression of local irritation by colotomy favors the spontaneous cure of the torpid lesions"

Panas' Total Combined Keratectomy —This operation avoids all the dangers and deformities of enucleation It is especially adapted to chronic glaucomatous and painful eyes, as it ends the pain and glaucomatous condition entirely and permanently It leaves a round, smooth stump, fully three fourths the size of the normal eye, movable and unatrophied, over which the artificial eye cap fits so perfectly that its artificiality is scarcely perceptible The fears of sympathetic ophthalmia are exaggerated in these days of asepsis He has only encountered one or two cases in the last ten thousand at the Hotel Dieu The operation as he has performed it on 200 patients, with or without staphyloma, consists in first passing a Reverdin needle through the sclero corneal limbus behind the iris and lens, carrying a silk thread, which is left for the first stitch of the suture and tied if the vitreus shows a tendency to escape The cornea is then removed with a Graefe knife held flat, cutting it into fifths and snipping off the last fifth with the scissors The iris is removed with the cornea if adherent, otherwise he performs iridodyalisis The lens is then removed with the spoon, the escape of the vitreum being carefully prevented The stump is sutured with a couple of stitches in the sclerotic and rounded off The surface is rinsed with a solution of mercuric iodid, dusted with iodoform and a roll of iodoform gauze applied with a dry cotton bandage outside The threads are removed the seventh day The danger of hemorrhage is very slight—3 cases in 200 If it occurs, the eye can be enucleated or eviscerated The latter leaves a fairly goodly stump He mentions in his communication to the Académie de Médecine (*Bulletin*, August 23), that Pritchard was the responsible author of enucleation, but that we have now progressed beyond it Keratectomy, effective and harmless, should take its place in many cases—another forward stride in ocular surgery

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable, at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Henry P Newman, 100 Washington St Chicago Ill sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character intended for publication in the JOURNAL should be addressed to the *Editor* and all communications relative to the business of the JOURNAL proof sheets returned or in regard to subscriptions should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL

SATURDAY, OCTOBER 22, 1898

THE POWER OF EPITHELIUM TO LIVE OUTSIDE OF THE HUMAN ORGANISM

It is a well known fact that when general death of the body occurs all its cells do not at once die Every surgeon knows that transplantation with bits of skin that have been removed from the body for some time give very good results Pieces of skin from dead bodies have been observed when placed on wound surfaces to form substantial and permanent cutaneous covering **WENTSCHE** transplanted skin successfully after having kept the pieces for twenty-four to forty-eight hours in physiologic salt solution **GARRE**, who examined into the histology of the healing process of transplantation, found that large cell masses could maintain their life and power of proliferation for more than forty-eight hours, although they were simply made to adhere to a wound surface and were without demonstrable blood circulation

Recently **LJUNGGREN**[1] undertook a series of experiments for the purpose of further studying the faculty of epithelium to preserve its vitality outside of the organism, especially in relation to transplantation He carefully preserved more than forty fragments of skin, most carefully disinfected, in glass tubes containing sterile ascitic fluid, for from two days to six months At different intervals microscopic sections were studied with a view to ascertaining the histologic condition of the pieces to his great surprise he found that even for as long as three months the epithelial cells on the deeper layers showed well nuclei and a good prot[illegible]cture **LJUNGGREN** made twenty-two efforts at transplantation with these pieces, and in sixteen instances the immediate results seemed to be wholly successful, in three cases, however, the grafts died, in two they were absorbed by the surrounding granulations, but in eleven instances permanent skin was formed The longest time that these pieces had been kept in sterile ascitic fluid was one month

Finally, in order to prove definitely that the epithelium of the transplanted preserved epidermis played an active part in the growth of new skin and acted not merely as protective coverings under which cells from the epidermis at the margins of the wound could creep, he placed some of the preserved pieces directly upon a muscular surface and 10 cm from the cutaneous margins, that is at such a distance from the skin that its cells could not possibly become mixed with those transplanted, some time after the transplantation he removed small pieces for microscopic examination, and it was found that there had taken place a marked proliferation of epithelial cells with numerous figures of nuclear division The epithelial cells not only grew over the surface of the wound but also showed a tendency to penetrate into the granulation tissue in a way that recalled the appearance of the development of a beginning carcinoma

These observations, although not by any means sufficient to permanently decide the interesting biologic problems involved, nevertheless seem to us to indicate the value of further and more extended and diversified experiments along these lines

EOSINOPHILIA

When it was found, not a great many years ago, that the presence of eosinophilic cells in the blood was not only not a characteristic symptom of leukemia, but that these cells were a constant constituent of normal blood, interest in them was to a large extent dissipated Only of late, since the findings of **OSLER**, **THAYER** and **CABOT**, of an enormous increase of these cells in the blood of patients afflicted with trichinosis, has anything like general interest been excited But during this interval much work has been accomplished in blood histology and pathology, and not a few important points have been established as regards the eosinophiles While the eosinophiles may be always found in the healthy circulating blood, yet their proportion to the various forms of white cells exhibits a considerable range, from one-fourth of 1 per cent In infancy even this ratio may be exceeded, so that we must not look upon an eosinophilia at that period of life, unless very pronounced, as pathologic

While no definite classification of the causes of eosinophilia [illegible] attempted, yet it seems to be particularly liable [illegible] when there is some disease [illegible] the [illegible], as in osteomalacia [illegible] are [illegible] shown by N[illegible] [illegible]nophiles are very scanty in the blood, they may exist in considerable numbers in the marrow of bones (and in other internal locations as well), and many have thought that their appearances in the normal circulating fluid is purely accidental The very large proportion of these leucocytes in infant's blood may, as suggested by CABOT, have some connection with the very rapid progress of growth in the osseous structures at this time of life In diseases of the spleen, many skin troubles, and affections involving the sympathetic system and the organs of generation, there may be eosinophilia Having determined by a differential count that this change does exist, it may be of aid to us in various ways for instance in hesitating between a tumor of one of the genital organs and a tumor of another part of the body, from what we have said before, an increase in the eosinophiles would favor the former, in a similar manner an eosinophilia in malignant disease would open the suspicion of involvement of bone either by direct extension or by metastasis

---

[1] Nordi Kt Medicin kt [illegible]

As regards prognosis, eosinophilia can not always be looked upon as a bad omen Even in such hopeless cases as leukemia, it is most conspicuous in the mildest type of the disease, the spleno-myeloginous, while in the other blood diseases, as pernicious anemia and chlorosis, it indicates a comparatively favorable course Mention was made above of the presence of this symptom in trichinosis In this disease the proportion of eosinophiles is largely in excess of that of any other disease as far as we now know Indeed, in one of THAYER's cases as high as 62 per cent was noted during the course of the acute symptoms In other cases in which tentative diagnosis of typhoid fever and malaria have been made, a blood count yielding an eosinophilia of 20 per cent has changed the diagnosis to trichinosis, which examination of portions of muscle obtained by puncture has subsequently confirmed In all these cases of trichinosis, it might be noted, a pronounced leucocytosis has always been present and the eosinophiles have gradually lessened with the disappearance of the acute symptoms

HOMICIDE BY MICROBES

The suspicional fear of the unknown which causes primitive races to believe that natural death can not occur, and that all deaths must be due to some malign influence, either supernatural or homicidal by poisoning, survives in this last phase among the English-speaking nations From this comes the detective mania so often exhibited by the press and the practitioner of "crowner's-quest law," who have been ridiculed since the time coroners were originated by the Norman kings to secure forfeiture of goods of felons for royal benefit (Green's History of the English People, Vol 1) In English-speaking countries, the coroner, as a rule, true to the detective theories which have given him birth, generally chimes in with the press in its detective predilection for criminal accusation, in violation of the central principle of the English common law that every crime must be proven beyond a doubt, and that every circumstance that can be construed reasonably in favor of innocence must be so construed As a result, whenever a supposed crime due to possible negligence by the paternal powers of the state, ignorantly supposed to be present in English-speaking countries, occurs, the press and the coroner seek for a scapegoat, and generally find it in the long-suffering, public spirited medical profession Denunciation of it does not affect any plutocratic "vested interest," as would denunciation of newspaper advertisers

An illustration of the primitive epidemic terror anent poisoning and of the tendency last mentioned recently occurred in England SIR JAMES CRICHTON BROWNE, one of the English-speaking authorities on forensic medicine, delivered an address before the British Pharmaceutical Society, in which he stated that there were organic poisons known to physicians which could be used with impunity by any criminal so disposed By keeping his own microbes, a connoisseur in poisons could, without the slightest fear of detection, slaughter hundreds of innocent persons The statement of such facts was fully in accordance with the scientific principle that science, like fire, purifies everything, and that exact truth must always be known so that its effects can be fully guarded against It is the unknown nature of poison which so frequently leads the poisoner to use arsenic and strychnin, when with a little knowledge he would be deterred from such crime by his certainty of detection Without any regard for scientific truth for the medical profession or the interest of justice as already defined in the English common law, A BRAXTON HICKS, coroner for the Kingston District, Surrey, England, in the course of an inquest held October 6, on the body of a country official who died from the effects of an untraceable poison, took occasion to score CRICHTON BROWNE's lecture in the strongest terms "Such talk," he said, "was not likely to further the ends of justice Dr BROWNE should have thought twice before disseminating such knowledge"

It is a singular illustration of coronorial tendency to omniscient ignorance of forensic medicine and its literature that Coroner HICKS, who has been in office many years, should have forgotten a famous typhoid epidemic at Buenos Ayres half a decade ago This was distorted by the English speaking press into a magnificent canard of poisoning by microbes According to the newspaper story, a merchant of that city, being upon the eve of bankruptcy, invites all his creditors to his house, instructing them to bring their receipted accounts Before proceeding to business the creditors are invited to a choice little dinner, including several kinds of liqueurs The Creme-de-menthe is iced with cubes of frozen water containing typhoid and colon bacilli galore Every one of the creditors dies from typhoid fever before leaving the house The crime would never have been detected, according to the newspapers, but that the butler ate one of the cubes The little touch about instantaneous deaths from typhoid in this tale should have destroyed its credibility Despite this, it passed muster and was widely quoted in newspapers, and even callow medical journals, with comments on the increased powers given the poisoner by bacteriology, and diatribes on the danger of such knowledge being communicated to the public Coroner HICKS never scored the skilled "wanderer from the hackneyed limits of the actual," who did this tale evolve from the depths of his inner consciousness OUIDA, in one of her splenetic, zoöphilic, anti-vivisection degenerate outbursts, wrote a most lurid novel called "Toxin," in which a vivisectionist was led by experiments on animals to the murder of human beings by the use of hypodermic injections of pathogenic bacteria and their toxins The picture of the vivisectionist physician is a greater caricature of the scientific experimenter, if that be possible, than WILKIE COLLINS' opium vision of the vivisectionist physician in "Heart and Science" Another novel issued at an earlier time, dealing with the same problem, did greater justice to the physician The use of pathogenic bacteria for homicidal purposes is by a degenerate, in contrast with whom is a physician replete with the altruistic impulses of the medical profession This novel —GRANT ALLEN'S "Devil's Die"—was published nearly a decade before OUIDA'S "Toxin," which it seems to have suggested It was widely reviewed in the newspapers of the English-speaking countries as well as in the literary reviews The story reeks with bacteria One very dramatic incident turns upon the attempt of the degenerate physician—who is a skilled bacteriologist—to poison his wife by the toxins and germs of cholera for the purpose of marrying a woman novelist The details of the culture of bacteria are given The methods of their hypodermic administration are fully described The physician is a descendant of a cruel East Indian woman who starved a slave girl to death in a cellar beneath her own room so that she might enjoy her death-cries The slave she regards as a rival claimant of the affections of her European husband The character of her descendant, the physician, which is of the unstable degenerate type, is chargeable, according to the "Devil's Die," to defective inheritance, not to scientific training In accordance with GRANT ALLEN'S notions of destroying race prejudice, an altruistic black Mohammedan physician of East India extraction is introduced as a foil to the degenerate before mentioned The two are friends Both work at the same problems in bacteriology and biology The first evidence of ruthlessness of the degenerate occurs when a sottish woman of the slums is brought to the hospital, badly injured by her husband for wilfully and brutally slashing her child with a glass bottle used as a candlestick Together with the injuries she is suffering from cholera nostra Her death from the latter is essential to the demonstration of a bacteriologic theory which the degenerate has evolved She rallies rapidly from the wounds and the cholera The degenerate, fearing for the success of his theory, sews a rubber bag in his coat, fills it with ice and, despite the precautions of the Mohammedan, who suspects him, succeeds in giving the woman a fatal chill with the hand which he has concealed in the ice bag The woman dies His bacteriologic theory is laid before the chief London medical society and endorsed by a thinly-veiled wraith of Sir WILLIAM JENNER Unfortunately the husband of the degenerate's victim is indicted, tried and convicted of murder Fortunately, however, for the degenerate, the trial violates the legal principle that the cause of death must be proven beyond a reasonable doubt The husband is therefore pardoned The degenerate gains great praise for his theory and is made by Queen Victoria professor of etiology in a London university He takes charge of the daughter of the murdered woman and is esteemed for his kindness to her She grows up perfectly devoted to him and learns the technique of bacteriology On visiting Cornwall, the degenerate and his Mohammedan friend rescue the crew of a dismantled ship laden with cholera cases The cases are taken into the house of a rector of the vicinity The degenerate and the Mohammedan both fall in love with the rector's daughter The Mohammedan, remembering the slave girl's story, is apprehensive of the future of the rector's daughter in case she marries the degenerate The marriage, however, occurs and proves happy for some years, when a female novelist appears on the scene, with whom the degenerate falls in love Determining to kill his wife, he substitutes a watch-glass containing cholera germs and toxins for a similar glass supposed to contain morphin The Mohammedan detects and changes the glasses which, however, are rechanged by the slum girl bacteriologist before mentioned The injection does not prove fatal, but the degenerate infects himself and dies from cholera The story is so told as to show that the injection of pathogenic bacteria and their germs is not always a success from the homicidal standpoint

The attempt by Coroner HICKS to limit the statement of scientific truth before a scientific body, can not but remind the student of forensic medicine that the position of the coroner as to forensic medicine is still as sapiently sciolistic as in the days of SHAKESPEARE, who thus ridiculed it in Hamlet

2d Clown —But is this law?
1st Clown —Ay, marry, is't, crowner's quest law

Disappearance of Tetanus —Benicio reports two cases in which the tetanic syndrome vanished with the appearance of measles, and Costa another in which it vanished in the course of an attack of violent diarrhea —*Brazil Méd*, September 1

"THE MOMENT AND THE ARTICLE OF DEATH"

It is not an uncommon practice in recent years for writers of fiction to attempt to portray the feelings of the dying in the supreme moment when the passage from the known to the unknown takes place, especially in case of violent or so called instantaneous death TOLSTOI, in his "Sevastopol," was perhaps one of the most successful in this line, but he has many imitators, some of them of very recent date in the literature incited by the recent military operations in Cuba and in the Soudan It is a curious fact that none or almost none of these imaginative writers have made the feelings of the subject in the instantaneous forms of death to any extent painful It would seem sometimes that the exaltation or intensification of feeling, the illusions of time and space that they describe were derived from some haschisch reminiscences, or something of the kind, rather than from any veritable experience narrated by those who have been very near and yet escaped death, the most obvious and natural source of data for building or modeling upon in such a matter The popular notion, judging from the sensational fiction, which presumably meets it best, is apparently that there is a hyper-consciousness at the moment of sudden death, but that the element of coarse material pain is generally lacking

There is a certain reasonable ground for this belief in such facts as those of electric shocks not apparently destroying consciousness but yet benumbing sensation, and other similar phenomena The facts of sudden death, themselves, so far as we can appreciate them objectively, do not indicate any probability of serious suffering or even of retention of any degree of conscious feeling whatever in most cases The imaginative creations of fiction writers have no real basis in scientific observation or experience so far as they attempt to portray in elaborate detail the last surviving consciousness of the victim, the fact is, we have no evidence or reasonable presumption that such exists, or that sudden death in appearance is not equally sudden and complete in reality

The only practical importance of this question, however, is in its relation to euthanasia, and as regards this, for the most of mankind, even this practical importance does not exist Men do not seek sudden death often for the purpose of avoiding the long drawn out pangs of ordinary dissolution, the normal man clings to life even with suffering The conscientious physician who attempts to benumb with anodynes the tortures of fatal illness does so in fear and trembling lest he may inadvertently cut short the allotted span of life of his patient, it is only with condemned criminals and those among them whose offenses have been so extreme that it is deemed right and expedient to put them out of existence, that modern humanitarianism can have full play in assuring them an absolutely painless exit from this life This is, in its way, an anomalous fact, and it need not be objected to, as it is in accord with the spirit of the times, which eliminates the retaliatory or revengeful element as much as possible from legal penalties, but it may be well to ascertain whether there are grounds for the belief that in any modern form of execution the element of painfulness exists to any serious extent The subject was discussed editorially in this JOURNAL a few months since and some apparent objections to present methods strongly stated It was shown that none of the present methods fully satisfied the humanitarian demands, that there was an apparent possibility of some discomfort, if not of actual pain, in every method of death that had been devised or prepared as a penalty for capital crime Even electrocution, which was adopted in New York as the method best satisfying modern ideas, has its hitches and delays, and death is not always clearly instantaneous, and now comes the report from Paris, through the public press, that a French physician has ascertained that even decapitation by the guillotine, which was supposed to be as nearly as possible an insurance of instant death, is anything but a success in that regard, and that decorporated heads retain a consciousness and exercise of their special senses for very appreciable periods of time after the operation According to the authority referred to, the brain retains blood enough for its nourishment for an hour after decapitation and absolute death does not occur for three hours To be sure, this contradicts well-known pathologic facts and theories, and the scientific exposé of his views and the grounds on which they are based has not reached us, but the statements go the rounds and excite comment and belief In no way would it seem that capital punishment can be carried out in an unobjectionable manner

The real question is, however, does actual pain exist at the moment of death, are not the senses so benumbed that the subject feels no pain, and do we not secure this in the methods of sudden taking off used in legal executions? The time-honored method of hanging is as barbarous as any in use in civilized lands, in appearance at least, yet those who have experienced it and been resuscitated do not as a rule describe it as agonizing—some of them, indeed, have described actually agreeable sensations, especially of a sexual order, and the very common phenomenon of priapism in the hanged would suggest that such may be very general A long drawn out hanging is not, however, a desirable mode of death in a theoretic point of view and the method is open to the charge of being behind the age and in a sense barbarous All methods that practically insure instant death, as do electrocution and decapitation, can not be really painful, for there is no reason to believe that the actual moment of dissolution is often, if ever, painful in itself, and if divested of needless accessories of publicity, etc, can hardly be called barbarous, that is, if the legal taking of human life is not itself a barbarism

The chief barbarism and torture of modern methods of dealing with capital crime is in the law's delays, the false hopes aroused, the long drawn out preliminaries, more than in the final execution of the offender The law plays with the criminal like a cat with a mouse and in so doing loses half the salutary terror she should excite against the commission of crime, while it aggravates the mental agony and suspense of the formally convicted And for all the rest of the world euthanasia is, in all probability, needed more in the precursors of dissolution than in the actual moment of death'

DESTRUCTION OF AN ARMY HOSPITAL BY STORM

The destruction effected by the storm of October 2 near Fernandina, Fla , has not been noted in the news papers, as telegraphic and railroad communications were interrupted for so long after the event, but reports recently received by the War Department show that the hospital of the Third Division, Fourth Army Corps, was completely swept away and the military part of Fort Clinch materially damaged The weather was threatening during the night of October 1, and the storm broke with great fury about 7 o'clock next morning The barometer stood at 29 02 inches, the wind was estimated at 100 miles per hour and the sea rose to such an extent as to constitute what is usually called a tidal wave Fernandina suffered severely Many buildings collapsed before the force of the gale The water was six to eight feet deep over many of the docks, and tugs and other light vessels were stranded in the streets of the town The quarantine station was washed from the face of the earth, as also was the hospital of the Third Division of the Fourth—General Coppinger's—Army Corps The hospital was on the beach, about two hundred yards from the surf, but separated from the ordinary high-water line by a range of sand-hills Fortunately most of the patients had been sent by hospital trains to the general hospital, Fort McPherson, Ga , on September 27, as it was the intention to abandon the site at Fernandina In a few moments after the onset of the storm the waves broke through the line of sand-hills and submerged the tents used as offices and officers' quarters An effort was made to save personal effects and the hospital records The latter were recovered and placed in the pavilion wards, which at the time were believed to be free from danger But as it soon became apparent that these would be swept away, the prompt removal of the patients was effected by litter They were carried to the Strathmore Hotel, some four hundred yards distant, but by the time this was accomplished the pavilions were destroyed and the hospital corps barely escaped with their lives in their unsuccessful efforts to recover the books of the establishment The water advanced on the hotel in which refuge had been sought, and the north end of it collapsed, while the south end remained comparatively secure Meanwhile, about 9 o'clock, an official of the Florida Central and Peninsular Railroad Company, realizing that the sick, the attendants and others at the hospital would be in great danger, took an engine and two freight cars, and calling for volunteers, succeeded in reaching the hospital, although the fire in the engine was nearly extinguished by the high water on the track He succeeded in carrying them to a high ground on the track, where they were safe, and whence, late in the evening, some managed with difficulty to reach Fernandina while others remained on the cars during the succeeding night Major W F Carter, surgeon U S Army, chief surgeon of the hospital, reports that his men behaved with the utmost coolness and made strenuous efforts to save property and lives They were up to the armpits in water in the work of rescuing women and children

Fort Clinch, an old artillery post, garrisoned for the first time in many years when war was declared, was greatly damaged by the storm of October 2 As at most of these old posts which have been recently brought into active service, the buildings were decayed and unfit for occupancy except under conditions of war The water rose to five feet in the quarters The medical officer, Dr Francis Lieber, was sick with typhoid fever at the time and was awaiting the arrival of Dr Shattuck from Hilton Head to relieve him After the storm Surgeon Carter, of the division hospital at Fernandina, sent one of his assistants, Dr Chmelicek, to bring Dr Lieber and his sick men to the city, about seven miles distant Dr Lieber died on October 11 He was the son of Gen Norman G Lieber, judge advocate-general of the army There is no doubt that the excitement occasioned by the storm had a harmful influence on the progress of the sickness

RED CROSS AID AT SIBONEY

The story of the work of the Red Cross at Siboney, when the Spanish troops interfered with the march of the Rough Riders and the Colored Cavalry to Santiago, was told very extensively at the time, and the refusal of the Army Medical Department to accept proffered assistance met with severe comment in many quarters To refer to it at this late date looks like being behind the times, but the fact is we have only now heard from the other party concerned The accounts already published came directly, or indirectly through the interviewer, from Red Cross sources, but now Colonel Valery Havard, who was chief surgeon of Wheeler's Cavalry Division, considers it proper for him in the interests of truth and justice to make to the Surgeon-General a statement of the facts as known to him, the officer most concerned His tale is interesting, otherwise, as presenting a graphic and unvarnished picture of the difficulties of the medico-military situation and the pitiable condition of our wounded or sun-stricken soldiers. He says:

The first division of our troops landed at Baiquiri and advanced swiftly to Siboney, which it occupied without resistance. On the 24th, the transport *Alleghany*, upon which I was, with other members of General Wheeler's staff, steamed down to Siboney, but it was only on the morning of the 25th that I was able to make a landing. This landing was accelerated by the news, brought by a newspaper man, of the fight which had taken place the day before in the jungle of Guacima. Fortunately we had kept on the upper deck, in an accessible place, three medical and surgical chests, quite a lot of additional articles, a small bale of blankets and a few litters. All these we quickly transferred to a row boat and successfully landed, so that there was no suffering, at any time, among my patients due to any want of medical attendance, medicines or dressings. We also had an abundance of rations, which were cooked and served without counting.

A large store room, much dilapidated but with plenty of doors and windows, seemed to be the best place for our provisional hospital; I already found a few patients there and hastened with one assistant surgeon, two acting stewards and four hospital corps men, to make the place as clean as possible. The wounded, some forty in number, were brought in during the whole day of the 25th, on all kinds of improvised litters, about five miles over a very muddy trail, in the heat of a tropical jungle, but all arrived safely. This transport by hand of the wounded by their devoted comrades struck me as hardly less heroic than the battle itself.

We laid the patients in two rows upon the hard wooden floor, with hardly room enough to pass between. We were almost entirely destitute of cots and blankets, the few litters we had brought from the ship being used as bunks for the worst cases. With and after the wounded, came in a steady stream of cases of heatstroke, remittent fever and dysentery. Soon the floor space in the main room was crowded, the patients lying side by side. Other adjoining rooms were utilized, light and ventilation being obtained by knocking down the partitions; but before long the whole building was overflowed and patients had to be placed upon a narrow rickety porch, more or less exposed to rain and sun. To make matters worse, cases of measles came and had to be provided for. This we did in a nearly contiguous rum shop, exceedingly filthy but with one front room susceptible of some degree of cleansing. In this we crowded twenty six patients, several sleeping on the large counter.

Our kitchen arrangements were a comparative success. We had an active and intelligent cook who knew how to hustle in an emergency. He got together the necessary utensils, and enough of substantial food was provided from the first. An unexpected and much prized discovery in the village, was a half dozen casks of excellent and wholesome Spanish wine, which was turned over to the hospital and probably saved several patients' lives.

However, our position was pitiful; the patients lying on the floor, mostly in their trousers and flannel shirts. With few exceptions they had thrown away blouse, blankets and ponchos. The blankets we had brought with us did not go far in this great need. The days were very hot but the nights unexpectedly cold and some thick covering was required for comfort. As already stated, we had nothing better to feed these men than the ordinary articles of the soldier's ration, with but few delicacies, which did not last more than a day; but notwithstanding this destitution, I do not recall that a single man brought into that building died there. In two or three days the hospital ship *Olivette* arrived and most of the wounded were carried upon her. On the 29th I transferred the few remaining patients to Dr. LaGarde and rejoined my division at the front.

From the beginning, Miss Clara Barton's ship, the *City of Texas*, lay in the Bay. Realizing the futility of expecting stores from the hold of our own ships, although anchored only a few yards from shore, I rowed to the *City of Texas* and called on Miss Barton the day after I took charge. She received me kindly, listened to my tale of suffering and promised to send some cots, blankets, and whatever food stores for the sick she could spare, the primary object of her charity, as she explained, being the Cuban rather than the American soldier. She was as good as her word. Only a few cots came, but the blankets were nearly sufficient to give one to all patients who were without any.

Next day, some of the members of her staff visited the hospital and, in my absence, asked my assistant what they could do for the comfort of the patients. This assistant took upon himself to decline their kind offer of services, not even notifying me of the occurrence. Here I may remark that I was surprised the gentleman who accompanied the ladies should not have inquired for the officer in charge of the hospital and responsible for it. Probably I was stealing a nap in some corner and could easily have been found. Therefore, I was amazed when, later in the afternoon, an elderly lady and a younger one appeared, both meeting me in the middle of the main ward with marked frigidity of manner and addressing me with unmistakable acerbity of tone. Sweeping their arms along the rows of patients, they asked me how I could stand unmoved at such a pitiful sight and scorn assistance when I stood in need of everything. The younger lady was particularly persistent in discharging her injured feelings upon my innocent head, and it required considerable self control not to betray myself into an expression of impatience. They told me all that they had accomplished at the Cuban hospital, half a mile away; how the floors had been scrubbed, fresh linen put on the beds and every patient made comfortable; that it was a shame they should not be allowed to do the same for the American soldiers. I succeeded, in time, in making them understand that a very unpleasant mistake had occurred, for which I was exceedingly sorry but blameless; that, on the contrary, I had, from the beginning, been hoping for their help and was ready and anxious to receive it at any time, the sooner the better. One of the Red Cross gentlemen joined us at this time and I offered him the same explanation and extended the same request. It was then agreed that the ladies would come the next day. They accordingly appeared in the forenoon and I showed them the uninviting field of their volunteer labor. The inquiry was naturally made, where they could find a room for themselves. I told them that there was absolutely none in the two buildings occupied by the patients, the medical officers taking chances at any unoccupied part of the porch. I took them about four hundred yards to a barn which had a habitable room, or rather a room which could have been made as habitable as could be looked for at that time and place. They consulted among themselves, gave me some evasive answer and went to the Cuban hospital, where they remained. Never afterward did they return to my hospital or offer personal services. In other words, to speak plain truth, an earnest appeal was made to them and they did not respond. Their reasons may have been good and I never questioned them, but I have wondered why in their accounts of those painful days, I am blamed for refusing the services of those ladies when, in fact, they refused to give the services that were asked.

This incident did not, however, alter my high appreciation of the Red Cross. Even at Siboney, if I missed the deft fingers of sympathetic nurses, I received substantial help in other ways. Later, at the field hospital, on the Santiago road, after the dreadful days of July 1 and 2 when I saw Miss Barton, with another lady, arrive on an army wagon over one of the worst roads in the world, and, without any rest, go to work and prepare soup over a camp fire, I realized that a society inspired by such a leader could not help being fruitful of good results. Therefore I obeyed a very natural impulse when, at Santiago, the day before her departure, I called on Miss Barton and, in the name of the Medical Department, expressed to her my grateful acknowledgments for all her society had done for us in our times of need.

CORRESPONDENCE

For a National Bureau of Health

DETROIT, October 14, 1898.

To the Editor:—It is now the time of the year that the medical men of the United States should be sounding the candidates for the office of United States Representative as to the position they are going to take upon the question of establishing the National Bureau of Health.

The Wayne County Medical Society of Michigan, the largest medical society in the State, excepting the State Society, passed resolutions last evening, appointing a committee to look after this matter, and also to inquire into the position that the State Representatives will take on this matter when the selection of United States Senators goes before them. Individually, several members of our Society have also taken pains to see various prospective candidates so as to place this matter before them in such a light that they may act intelligently upon the question when presented to them; and if a candidate refuses to co operate with us, then it is proposed to "snow him under" at the polls

I am satisfied that had this National Bureau been formed a year ago much of the terrible deprivations and sufferings that overtook our boys in the field would have been largely reduced, for had President McKinley had at his elbow a man in touch with all the leading health organizations of the States, as he would have, had this Bureau been formed as the Committee of the AMERICAN MEDICAL ASSOCIATION had it mapped out, a better selection for Army camps would also have been made

While I do not wish to criticize at all the work of Surgeon General Sternberg—for I consider it magnificent—yet, at the same time, I feel that had he had the aid of some one at head quarters, in the President's Cabinet, who was a careful, conscientious medical man, that the medical record of the army would not have been surpassed in the history of active military campaigns

With this view, I ask your readers everywhere to put into operation the necessary measures for explaining these matters to the Congressional candidates, and for those of the State Legislature, so that in the coming year our representatives can work more in harmony upon this all important medical question—the establishment of a National Health Bureau

Some of the present United States Senators and Representatives are warmly in favor of the bill advanced by the Committee of the AMERICAN MEDICAL ASSOCIATION, introduced by Senator Spooner, and we are satisfied that many of the other members of both the House and Senate would be as warmly committed to its provisions if they only knew its far reaching beneficial results Yours truly,

C HENRI LEONARD, M D

Another Cataractous Family

WHEELING, W VA, Oct 15, 1898

To the Editor —About two years ago, in the *New York Medical Journal*, I reported "A Cataractous Family," in which the mother, three daughters, and possibly two sons, have had cataracts at about the age of 40

I operated today on a mature cataract in the right eye of a man named Reason Goddard, farmer, aged 67 It had first begun to dim his sight sixteen years ago One in the left eye is about half formed

His father had cataracts in both eyes, well matured, when he died at the age of 68

An older sister of the patient was blind from cataract and was operated on at about the age of 50

Another sister, aged about 60, has a mature cataract in the right eye

Two male cousins, sons of his father's brother, had cataracts in both eyes when about 60 years of age

JOHN L DICKEY, A M, M D

SOCIETY NEWS

Postponed —The Southern Surgical and Gynecological Association has postponed its Memphis (Tenn) meeting until Dec 13, 14 and 15, 1898, on account of the prevalence of yellow fever

American Microscopical Society —This society at its recent annual session, elected the following officers for the ensuing year President, Dr William C Krauss Buffalo first vice president, Prof A M Bleile, Columbus, O, second vice president, Dr G C Huber, Ann Arbor Mich, secretary, Prof Henry D Ward, Lincoln, Neb, treasurer, Magnus Pflaum, Pittsburg, executive committee, Prof S H Gage, Ithaca, Dr A Clifford Mercer, Syracuse, and Dr V A Moore, Ithaca

American Electro Therapeutic Association —This association, at its eighth annual meeting in Buffalo, N Y, held September 13, 14 and 15, elected for president, Francis B Bishop, Washington, D C, vice presidents, Ernest Wende, Buffalo, N Y, William P White, Boston, Mass, secretary, John Guerin, Auburn, N Y, treasurer, Richard J Nunn, Savannah, Ga

Wayne County Medical Society —At the regular meeting, held October 13, in Detroit, Dr K Gunsolus read a paper on "Cranial Abscess" He said that, in the early '70s, when he first began to practice medicine, he passed through an epidemic of cerebrospinal meningitis, in Monroe County, Mich The epidemic began in the spring of the year and continued with more or less severity for about a year Great numbers had been attacked and the mortality was high, many of the deaths being due, no doubt, to the formation of pus in the cranial cavity No attempt at relief by surgical interference had been done, for brain surgery was then in its infancy While there is an increasing field for the general surgeon in this branch of science, there is more work and more attainments to be accomplished by the ear specialist in this direction than any other, for it is conceded, and statistics show, that more than one half of the cases of cranial abscess arise from a suppurative process in the middle ear As to the other causes of cerebral abscess, we have first, traumatism, more frequent than severe, though it may follow a slight injury and a long while after the injury has been received In these cases the abscess is always found at the seat of injury Another cause of cerebral abscess is caries or suppurative processes in the orbital cavity, the antrum of Highmore, or the nasal cavity Boettcher reported a case where a cerebral abscess was secondary to an abscess of the lungs Lastly, there are the so called idiopathic cases, which some so stoutly deny having any existence The doctor then entered into the symptoms, including the localizing symptoms by which it is possible to tell more or less accurately the location of the abscess, enumerated the diseases from which cranial abscess should be differentiated, and gave the treatment, which is the evacuation of the pus with good drainage, as in abscesses elsewhere Drugs of any description amount to nothing

NECROLOGY

H A GILMAN, M D, for many years superintendent of the Hospital for the Insane at Mount Pleasant, Iowa, died October 9 Dr Gilman was a man of rare executive ability, and came to Iowa from the institution of like nature at Jacksonville, Ill, where he had been assistant physician fifteen years The hospital at Mount Pleasant stands as a monument to his general capabilities as a manager He was graduated from Dartmouth Medical College in 1867 He was 53 years old

NATHAN SMITH LINCOLN, M D, University of Maryland, 1852, a well known physician of Washington, D C, died there October 3, aged 70 years He was an emeritus professor of surgery to the Columbian University at the time of his death and was also a member of many medical societies, and of late years in high esteem as a consultant He will be recalled by most of the profession as an attendant of President Garfield during the last months of his life

FRANCIS LIEBER, M D, an acting assistant surgeon U S A, Judge Advocate General Lieber's oldest son, died of typhoid fever at Fernandina, Fla, October 10

HENRY CLAY BAKER, M D, Malvern, Ark, October 9 —— C M Holmes, M D, first assistant physician at the Northampton Hospital for the Insane, Northampton, Mass, October, 7, aged 49 years ——Charles L Fox, M D, Lowell, Mass, aged 28 years ——Calvin Morgan, M D, Dugansville, Ky, October 3 ——William Pratt Read M.D Philadelphia, October 8, aged 51 years ——John G Stuart, M D, Fortville, Ind, October 7, aged 73 years

PUBLIC HEALTH

Health in Michigan – Reports to the State Board of Health for September give the five most prevalent diseases as Diarrhea, rheumatism, neuralgia, bronchitis and tonsillitis Compared with August (vide JOURNAL, p 803), typhoid fever, influenza, remittent fever and tonsillitis increased in area of prevalence

The Bacillus Icteriodes —The report on Sanarelli's work in regard to yellow fever, presented recently to the Rio Janeiro Academy of Medicien, by A Ramos, confirmed all his statements concerning the etiology and agent of the disease, but failed to confirm his therapeutic and prophylactic serum treatment, which is "still an aspiration"—*O Brazil Médico*, August 1

Solid Diphtheria Serum —This appears as a yellowish or whitish powder or yellow transparent leaves, which dissolve in ten parts water to a fluid resembling fluid serum in color and aspect The standard established by the German authorities is 5000 immunity units to 1 gram, and the price not above two marks for 200 units or eight marks for 1000 units —*Klin Therap Woch*, September 11

Prophylaxis of Measles —Widowitz has been studying several extensive epidemics of measles, and he now announces that epidemics could be prevented by the simple measure of closing the schoolroom in which the first case was noted, from the ninth to the fourteenth day after the first indications were observed, and the parents of all the children in this room ordered to keep their children away from other children during these distinctly specified five days Children from the same house could then return to school if provided with a physician's certificate that they have previously had the measles —*Vienna Klin Woch*, No 36

The Water Supply of Northeast London —The citizens of London are unable to cope with their water supply companies, among which there seems to be not much reciprocity The East London Waterworks Company does not keep faith with its customers, and a correspondent writes that an *émeute* of the population is to be dreaded The Royal Commission, which leans somewhat to the management by the companies themselves of their own affairs, may recommend "the amalgamation of all the companies into one central scheme under the control of a public body, perhaps the London County Council" The water companies were repeatedly urged during the last twelve months to connect their systems and be prepared to help one another in an emergency, but nothing was done For a truth small communities have the greatest bliss, since with them dividends and stockholders are not widely known

Yellow Fever —After our report of last week was prepared, Jackson, Miss, reported 9 new cases, on October 10, with 14 new cases at Harriston, 1 more at Canton, 15 at Madison, 1 at Oxford, 1 at Meridian, 1 at Taylor's Station, 6 with 1 death at Orwood and 8 at Hattiesburg On the same date Louisiana reported New Orleans, 4 new cases and 1 death, Wilson, 8 new cases, Houma, 10, Franklin, 14 and 1 death, Clinton, 3, Lake Charles, 1, Crystal Springs, 4, Ridgeland, 1 October 11 reports gave Jackson, Miss, 11 new cases, Poplarville, 7, Madison, 3, Harriston, 13 and 1 death, Hermanville, 1, New Orleans, 2, Franklin, 16, Wilson, 10, Houma, 1 and 1 death, Alexandria, 7 and 1 death On October 12 Oxford reported 10 new cases, Edwards, 6 and Waveland 6, New Orleans, 2 and 2 deaths, Franklin, 2, Wilson, 17 and 1 death, Baton Rouge, 10 On October 13, Jackson's record was 14 new cases and 1 death, Natchez, 6, Madison, 5, Starkville, 1, Oxford, 1 death, Hattiesburg, [illegible] new cases, Harriston, 16, New Orleans, 2, Wilson, 8, Alexandria, 6 and 1 death, Houma, 11, Amite City, 1 and 1 death, St Clair 11 and 1 death October 14, Jackson, 10 new cases Taylor's Station, 1, Poplarville, 12, Madison, 6, Waveland, 2, Hattiesburg, 3 and 1 death, Natchez, 4, Harriston, 3, Oxford, 1, New Orleans, 1, Franklin, 13 and 1 death October 16, Jackson, 8 new cases, Yazoo City, 6, throughout the State, 19 other new cases and 3 deaths, Franklin, La, 22 new new cases As we go to press, the report for October 17 gives 15 new cases at Jackson, and 23 with 2 deaths at other points in Mississippi

Proclamation of the Florida State Board of Health

OFFICE OF AGENT OF
STATE BOARD OF HEALTH OF FLORIDA,
KEY WEST, FLA, Aug 18, 1898

To the Public —On Tuesday afternoon, the 16th inst, a telegram was received at Port Tampa from the agent of the State Board of Health at Key West, stating that three cases of yellow fever were reported at the U S Marine Barracks, corner of Whitehead and Eaton Streets, Key West, but that he did not diagnose them as yellow fever Leaving Port Tampa the same night on the *Mascotte*, Key West was reached at 4 P M the following day As soon as practicable the cases reported to be yellow fever were seen, together with several cases of other sickness, which were all in the same ward and building In a careful examination and study of their histories then, and a subsequent examination this morning, I am unable to confirm the diagnosis of yellow fever

In making this statement the State health officer would do justice to the members of the medical profession here, as well as to those of the Army and Navy and Marine Hospital Service who have seen the cases, and from whom he differs in diagnostic points of symptomatology, and that he is alone in his opinion and decision but he is quite willing that any medical man elsewhere shall visit this place and investigate for himself, in fact he invites the closest scrutiny and probing of these and any other cases of sickness which have occurred at Key West this summer

The logical sequence of events must demonstrate the correctness or incorrectness of the opinion of the State health officer At the same time, being aware that no one is infallible in judgment, and that a great responsibility rests upon the State Board of Health of Florida in protecting the citizens of the State and United States against contagious and infectious disorders, and as United States Government officials have reported to Washington the existence of yellow fever before notifying the local health authorities, as required by the laws of the State of Florida and of the United States of America, the State health officer, before examining the cases reported to be yellow fever, realizing that publicity had created concern among the people of the country, desired to guard against any possible danger by giving every guarantee, therefore as a measure of extraordinary precaution, prescribes the usual regulations as if yellow fever prevailed at Key West Immunes may pass through the State, their *personal effects subject to disinfection* Non immunes will be subject to at least five days detention at U S Camp at Egmont Key Key West will remain under observation, with a view to preserving the public health, and modifications of quarantine deemed necessary will be made from time to time

JOSEPH Y PORTER, M D,
State Health Officer

KEY WEST, FLA, Sept 4, 1898

To the Public —On the 18th of August a statement was made that the State health officer had not seen a case of yellow fever in Key West among the U S Marines, who were then reported as sick of that disease, although he was only one of many of his professional brethren of both civil and military life who entertained a contrary opinion Since that time he has seen cases of similar sickness to that of the marines in civilians, and he has information of many cases like in character among the native population He does not now believe the prevailing fever to be yellow fever, because of the time of attack, in the day while at work, and not at night in bed, which latter is the invariable rule in yellow fever, the albumin in the urine of all cases examined, except in one case out of sixty, and then coming too early and disappearing too soon, the trivial gastro intestinal irritation and persisting vomiting nor gagging, a return to health with little or no medication or attention, some continuing to work with considerable fever, and the lack of fatality These are salient points, all in their absence adverse to a yellow fever diagnosis

The State health officer can not positively declare the prevailing fever to be *dengue*, although he so believes, because of the absence of a rash, which is generally present even in a limited number of cases, and thus is characteristically diagno sis This febrile disturbance now existing here, is evidently transmissible, from the "falling down" of many persons in different parts of the city, and it is because of this, and of a doubt as to the true nature of the disease, which is entertained and expressed by Dr R D Murray of the U S Marine Hospital Service, a medical expert of the U S Government, who came here at the request of the State health officer, and because further, when this doubt is known, should the quarantine against Key West from the mainland of Florida be raised, the neighboring States and the U S Government would immediately place a restrictive embargo against the whole state of Florida, that it is deemed both wise and prudent to continue the restrictions on travel from Key West for a few days longer, in the hope that the type of the disease, whatever it is, shall become so pronounced that there may be no mistaking its identity It must not be forgotten that a terrible responsibility rests upon the State and U S health authorities—on the one hand to protect the health of the people, and on the other not to needlessly intérfere with their commercial life—and that an error of judgment in the character of any transmissible disease may entail suffering, grief and great commercial disaster elsewhere in the country

The experience gained at Ocean Springs, Miss , and at Flomaton, Ala , last year when a great number of cases of "fever" developed within six weeks before a death occurred or the disease was suspicioned, "must give us pause," and the sensitively critical of our people on the subject of quarantine must not overlook the fact that there has been a division of sentiment and opinion among the medical men of the locality, as well as among the Government medical officers, which will have its impress and influence outside of Key West

For these reasons, which are considered sufficiently potent to warrant soliciting consideration, the State health officer asks that the citizens of Key West will with their usual patience bear with the health authorities of the State in this dilemma, and assist in the effort to conserve the interests of the commonwealth and of other States

Joseph Y Porter,
State Health Officer of Florida

I concur in the above
R D Murray,
Surgeon U S Marine Hospital Service

Executive Office,
State Board of Health of Florida
Key West, Fla , Sept 8, 1898

To the Public —When on the 16th and 17th of August yellow fever was officially reported to Washington by navy, army and other physicians, as existing at the U S Marine Barracks in Key West, the diagnosis was disputed on the 16th (next day) by the State health officer of Florida who had been summoned from Port Tampa to investigate the case, but as he stood alone in his opinion, he then stated that "the logical sequence of events must demonstrate the correctness or incorrectness of the opinions expressed "

On September 4 he again stated that, the "prevailing fever" in Key West was not yellow fever, but dengue However, as U S Medical Expert, Dr R D Murray, of the U S Marine Hospital Service, who came here at the request and urgent invitation of the State health officer (because of the contention of himself with other medical men, both civil and military), was not yet satisfied as to the true nature of the "fever" the indulgence of the citizens of Key West and the public in general was asked for a further delay of a few days to satisfy this doubt, before removing the restrictions on travel from Key West, which had been in force since the 18th of last month

The "logical sequence" has resulted in positively affirming the position taken at the beginning by the State health officer and by Surgeon A H Glennan, Marine Hospital Service, after his arrival here The characteristic rash of dengue has been seen in several cases on the island, and P A Surgeon H D Geddings, U S Marine Hospital Service, at the U S Marine Hospital Camp of detention at Egmont Key, wires that a passenger from Key West, August 22, developed at his camp, a typic case of dengue, with chill, fever, joint pains, fine rash, but no albumin He was sick four days, and afterward was discharged from the camp well

Again P A Surgeon L L Williams U S Marine Hospital Service, wires that he has seven cases of fever at Tortugas, three of whom have the rash of dengue

If any further confirmatory evidence is required to the observations already made here, the case at Egmont Key Camp and the case at Tortugas add a strong convincing link in the chain of substantial proof

In addition to the foregoing, Surgeon Murray states that is convinced that the "prevailing fever" is dengue and not yellow fever

Therefore the quarantine [illegible] *West are removed*

It is due however to the public to state, that dengue which is now prevailing here, is an infectious disease, causing generally several days of discomfort, but is not fatal

Joseph Y Porter, State Health Officer

DENGUE FEVER

Jacksonville, Fla , Sept 16, 1898

Dear Doctor —I have already notified you that dengue fever existed at Key West, and the necessity for not confounding it with mild yellow fever, i e , in my circular letter of the 10th instant So little has been written of late years upon this subject, however, that I have decided to take the liberty of calling your attention to characteristic symptoms which can not fail to be of help in the differential diagnosis I would not do so—for I presuppose that you are fully acquainted with dengue in all its peculiarities—but for the apprehension which would follow a false diagnosis in either case

As you know, it is an infectious disease, but not fatal, and *not quarantinable* It usually attacks or seizes one during the day time, and not, like the yellow fever, in the wee small hours—1 to 5 or 6 A M There is slight gastro intestinal disturbance No tendency to hemorrhage But a very small percentage of cases show albumin A rash appears on the decline of the fever seen frequently in the mouth when absent on the body Remissions of fever, looked upon as relapses, because recurring after the first or initial fever has been absent, a day or two The tongue of dengue is generally that of a malarial disorder—a broad, flabby and tooth marked tongue, with whitish coat Pepper's Text Book of Medicine (1893), Vol i, contains quite an interesting and accurate article on dengue by Dr Pepper himself

Very truly yours
Joseph Y Porter, M D ,
State Health Officer

BOOK NOTICES

Transactions of the Rock Island Medical Society Vol v Part iv 1897 Paper Pp 135 Illustrated Providence Snow & Farnham 1898

This pamphlet contains the proceedings of the quarterly meetings, held March 4, September 2 and December 2, and the annual meeting held June 3, 1897, also obituaries of Drs H E Turner, Charles O'Leary, A A Saunders, W E Anthony, A H Nickerson, D H Sullivan and W E Coyle, and the following papers "Specialism, the Laboratory and Practical Medicine", "The Therapeutic Value of Nebulized Fluids", "Pelvic Suppuration, Treatment by Vaginal Drainage", "Serum Diagnosis of Typhoid Fever", "A Case of Laminectomy for Spinal Injury", "Two Cases of Laminectomy", "Laminectomy in Spinal Injuries", "A Case of Tetanus, with Recovery", "Case of Asthenic Bulbar Paralysis", "The Physician upon the Witness Stand", "A Case of Cerebral Cyst "

Transactions of the Texas State Medical Association —Cloth Pp 310 Austin Eugene Van Boeckman Pub Co 1898

One of the most attractively gotten up volumes of transactions, this one is a decided addition to the physician's library The paper and presswork are excellent and the contents, comprising the usual topics found in society transactions, well arranged The volume covers the proceedings of the thirtieth annual session, held at Houston, Texas, April 26-29, 1898 The papers, as presented at the meeting, are grouped under the headings General Medicine Obstetrics and Diseases of Children, Surgery, Gynecology, Ophthalmology and Otology, and number thirty four, many with discussion appended

Proceedings of the Connecticut Medical Society Pp 445 Published by the Society 1898

This volume contains the usual data found in "proceedings," and the following papers read at the one hundred and sixth annual meeting, held at New Haven, May 25 and 26, 1898 "R [illegible] the Progress [illegible] "Angioneurotic [illegible] ngue" " [illegible] onsils", "Acou [illegible] es", "Thera- [illegible] "The Nev [illegible] phtheria [illegible] of Fifty

Cases", "Mushrooms and Mushroom Poisoning", "The Relation of Muscular Co ordination and Trauma", "A Case of Pachymeningitis Interna Hemorrhagica", "A Case of Double Homicide", "Some Remediable Forms of Sterility", "Puerperal Eclampsia", "Ophthalmic Science in Its Application to School Hygiene", "Physician Heal Thyself", "Progress of Surgery", "Progress in Gynecologic and Genito Urinary Surgery", "A Complicated Case of Intussusception", "Surgical Puerperal Septicemia" There is also a report of a committee on matters of professional interest in the State, covering "Malaria in Children," "A Certified Milk Farm" and "Interesting Cases in Practice"

Minutes of the Mayville Meeting of the Kentucky State Medical Society Paper Pp 36 Louisville John P Morton & Co 1898

These minutes are for the meeting held May 11–13, 1898, the Committee on Publication deeming it best to issue only the minutes of this session of the Society, and not the papers presented An alphabetically arranged roster of members is included The paper and presswork are excellent

MISCELLANY

Quadricentennial of the Discovery of Brazil—To commemorate this anniversary in 1900, for which great preparations are being made, the physicians of Brazil have undertaken to publish a work on "Intertropical Pathology," and the pharmacists a "Brazilian Pharmacopeia"

A Long lived Couple—Madam Henriette Simonet recently died at the Salpêtriere, aged 105 years and 6 months In 1810 she married her only husband who died Nov 18, 1890, aged 100 less 3 days Their daughter, now 78 years old, is still an inmate of the institution

Hypnotic Suggestion in the Treatment of Epilepsy is recommended by Bérillon, who has witnessed a remarkable modification of the character of epileptics to whom it was suggested to resist their impulses and neutralize their automatic habits The number of the attacks also decreased This treatment is not applicable to the insane or imbecile —*Revue Méd*, September 28

Thirteenth International Medical Congress—Brouardel is chairman of the committee of organization, with Bouchard and Marey, vice presidents, and Chauffard general secretary Lannelongue is chairman of the executive committee, which includes the general secretary and Bouchard, Bouilly, Brouardel, Dieu, Gariel, Le Dentu, Malasser, Nocard, Reymond, Rendu and Roux The Congress will open August 2

Chloroform and Gas Light Intoxication—Famulari describes the products of the combination of chloroform and gas light as free chlorin, volatile hydrochloric acid, carbonic acid, etc (*Policlinico*, June 15) Lorentz of Bochum reports in the *Zeitschft f Med Beamt* No 3, a severe intoxication following a three hours' narcosis The patient died in six hours, the attendant nurse in twenty eight and the operator was at the point of death for several days but finally recovered All had experienced a spasmodic cough during the operation —*Munich Med Woch*

Oblique Heredity—Beugnies remarks that the "newcomer who fecundates a widow mother or a girl mother, accomplishes a three sided fecundation," and mentions the following instance a girl bears a child to a tuberculous man and both man and child soon die of tuberculosis The girl returns to her native town and marries another man, but the first three children born to this couple, who are both perfect specimens of health, die of tuberculous meningitis in early childhood, and the other child growing up apparently healthy, and marrying an apparently healthy man, bears children all affected with tuberculous ganglions —*Journ de Méd et de Chir Prat*, September, 10

The Abatement of the Invective Nuisance seems at hand The "agin the government" people having had their benefit of reiterations and charges of incompetency, seem to be preparing winter quarters A short war on the whole satisfies the multitude, more particularly since the popular officers of the army have spoken freely of arrangements that were beyond criticism The medical department is now in course of vindication by "the sober second thought"

Agglutination of the Blood Corpuscles—Elfstrand announces that the poisonous albuminoids—ricin, abrin and crotin—derived from the crotin seed, produce a marked agglutination of the red corpuscles Ricin and abrin produce it in nearly every kind of blood, while crotin only affects certain kinds Two drops of blood from two different animals, impossible to distinguish by macroscopic or chemic tests, can thus be readily differentiated with crotin, human blood and pig blood, for instance, which may prove important from a medico legal point of view —*Klin therap Woch*, September 11

Muscular Rheumatism—Erben has been investigating 200 cases of lumbago and finds that the trouble is not muscular as supposed, but proceeds from an affection of the lumbar vertebræ with sensitiveness to pressure over them (119 cases) or else from neuralgia of the cutaneous nerves, proceeding from the third posterior lumbar branch, with the painful region on the buttocks instead of over the spine A third group was a combination of these two affections In the other twenty four cases it was impossible to found a diagnosis in nine, in the test the lumbago could be traced to alcoholism, to incipient tabes or osteomalacia He also attributes to the cervical vertebræ and the nerves emerging from them the etiology of wry neck, twelve cases The muscular contraction follows secondarily, as the head is twisted to prevent pain —*Cbl f Chir*, September 10

"Heart Epilepsy"—H Beer does not consider epilepsy a disease, but only a symptom resulting from cumulative irritation of the cortex This irritation may be hematogenic, reflex or traumatic, and the various neuroses correspond to varying grades of the same condition affecting different persons differently A few rare cases of "reflex" heart epilepsy have been recorded, due to arteriosclerosis or valvular insufficiency, and Beer now reports a case of epileptic attacks occurring in a woman of 50 years with hypertrophy of the right ventricle for seven years consecutive to emphysema of both lungs, causing dyspnea and palpitation at the least exertion No attacks have occurred since the five in the first three months during which he administered 2 grams bromin (Sandow's effervescent) with inhalations of oxygen and 5 gram nitroglycerin tablets twice a day —*Klin Therap Woch*, September 11

Statistics in Regard to the Sexual Life—A prominent Russian physician, whose name is withheld, writes to *Wratsch*, suggesting that some medical journal undertake the task of collecting and tabulating statistics in regard to the sexual life, to be sent in anonymously by physicians who realize the inconveniences and even dangers of the present lack of definite standards on this delicate subject, and would be willing for the benefit of science to note the particulars of their personal sexual life He suggests the following points 1 Sex 2 Age 3 Family relations, married, free love, etc 4 Masturbation 5 Age at first sexual intercourse 6 Largest number of cohabitations in twenty four hours, at what age? 7 Impotantia cœundi, at what age? 8 Ever any symptoms of any abnormal sexual impulse, at what age? 9 Ever affected with syphilis, ulc mul or gonorrhea? 10 Were there ever any abnormalities in the sexual function? He sets the example by extracts from his own note book in which for twenty-five years he has recorded his experiences on the above points, influence of seasons, etc —*Dermatol Cbl*, September

Internal Endodiascopy —L Bouchacourt, in his thesis, Paris, 398, confirms his announcement of the value and harmless ess of fluoroscopy and radiography by the introduction of a ong narrow Crookes' tube into the natural cavities of the ody, especially the vagina (*vide* JOURNAL, page 933) He tates that the static machine is the only safe one to use The acrum and symphysis can thus be inspected to the moment f fetal engagement The shadows cast by the bones in the eighborhood are much more distinct than by the usual ethods, as there are no superposed planes, and there is less ubstance for the ray to penetrate, while the screen or plate an be applied geometrically close to the organ to be inspected -*Presse Méd* , August 24

Cure Worse than the Disease, the Latter is Expelled —The physics f the sense of smell has been brought up for study and dis ussion, in a prominent fashion, by Professor Ayrton's address efore the British Association meeting at Bristol The follow ng paragraph in the *New York Sun* gives intimation that here is a physic through the olfactory sense "It is said that in ustralia there is a hotel where rheumatic patients congregate Whenever a whale has been taken the patients are rowed over to the works in which the animal is cut up, the whalers dig a narrow grave in the body, and in this the patient lies for two hours, the decomposing blubber of the whole whale closing around his body and acting as a huge poultice This is known as the whale cure for rheumatism "

The German Congress of Railway Physicians met at Cologne in September, where the arrangements for night lodgings and day waiting rooms for the employes were recommended as models The necessity of annual vacations, lasting several weeks and longer, in proportion as the service is exacting and the employe is older, was emphasized Brahmer asserted that the years of service of a locomotive engineer should be calculated double, as few ever attain the twenty five year pension limit The dissemination of trachoma by the cushions in cars was reported from the eastern provinces The inexpensive, disinfectant soap—Dr Graf's byrolin—was recommended for railroad purposes, indorsed by the higher authorities The duties of the railroad physician include, it was asserted, the hygienic supervision of employes' waiting rooms and dwellings, of their clothing and of their leisure hours, as the safety of the traveling public demands a healthy mind and body in everyone connected with the running of a railroad —*Munich Med Woch* , September 20

Electric Treatment of Catarrhal Affections of the Adnexa —The *Bulletin d'Electrotherapie* for August, is entirely devoted to a description of the cure of sixteen cases of chronic endometritis and metritis and complicating salpingitis, with or without ovaritis In one case there was also an inflammatory tumor of the right adnexa as large as an orange, in another the cervix was ulcerated All were completely cured without surgical intervention, with anatomic regression of the lesions, by Apostoli's method of electric treatment, in fifteen to twenty five minute seances Nine have borne children since All have been seen from one to several years afterward and the permanency of the cure established Negative, the continuous current (galvanic) acts as a resolvent, positive, weak, as a sedative and decongestive, strong, as a sterilizer, microbicide and modifier of the uterine mucosa The tubes contract, evacuate their contents, and the entire commotion gradually subsides

Artificial Cornea for Leucoma —T v Shroder presented a patient at the meeting of the St Petersburg Medical Society, April 28, whom he had cured of leucoma totale corneæ by the introduction of an artificial cornea made of rock crystal and platinum, with several small hooks at the rear of the platinum setting, which bore into the leucoma tissue and hold the prothesis quite firm Salzer of Munich found that rabbits bore a similar contrivance a year without inflammation Schröder's patient was blind from lime corrosion in the other eye, and the leucoma had developed after smallpox in childhood The crystal cornea showed a tendency at first to work its way forward, but a narrow band of tissue soon formed around the edges and held it in place There was no pain, no inflammation at any time and the tension was always normal He counts fingers at 2 25 meters and recognized colors The eye does not water except with very bright light, with an ordinary shield it bears the daylight without trouble An extremely delicate gray membrane formed over the back of the crystal, soon after its introduction, but it has not increased in thickness during the thirteen months since, and the results are considered satisfactory enough to warrant the application of the method on a larger scale A similar membrane formed rapidly and so thick in Salzer's one case that the vision was only slightly improved by the operation He attributed this to the profuse hemorrhage during the trephining The simple technique is described in the *St P Med Woch* of September 11

Annual Report of the Craig Colony —The annual meeting of the Board of Managers of this Institution was held at the Colony on the 11th instant, and the following officers of the Board were re elected Frederick Peterson, M D , president, H E Brown, secretary, John F Connor, treasurer The annual report of the Medical Superintendent, Dr William P Spratling, was presented and read The most gratifying feature of the report was the discharge of seven patients during the year as recovered It was also reported that marked improvement had taken place in a vast majority of all cases admitted to the institution The industrial showing for the year was exceedingly gratifying, the value of all articles grown on and manufactured by the Colony during the year amounting to $36,889 03 Eighty six per cent of all male patients and 83 per cent of all female patients were reported as engaged in labor designed to reduce the cost of maintenance The Medical Superintendent called attention to the fact that he had on file, on the first day of October, applications for the admission of over 600 patients that he could not receive on account of lack of room, and in view of the great pressure that is becoming greater each day for the admission of patients, the Managers decided to ask the coming Legislature for a large sum for dormitory construction It is sincerely to be hoped that in view of the value of this institution and its benefit to mankind, which benefit has already been amply demonstrated, the New York Legislature will see fit to grant any reasonable request that the managers of the institution may make

Fat Embolism in the Lungs from a Medico legal View —Carrara found 27 cases of fat embolism in the lungs in 102 cadavers at the Vienna Medico legal Institute It was especially noticeable in 13 out of 17 cases of fractures, the negative cases included 3 of fractured ribs and 1 of fractured ribs, sternum and radius It was found even in cases in which death had followed the injury at once There is nothing characteristic about the symptoms to distinguish it from shock and concussion of the brain The discovery of abundant and diffuse fat embolism is of great importance in deciding the cause of death The findings were positive in 7 out of 28 cases of affections of the heart, vessels and kidneys, but, of course, the fat may be derived from fatty degeneration of these organs and the not infrequently agonal injury may participate in the formation of the embolism It was also noted in the case of a boy of 12 years, whose knee had been crushed and ileum ruptured, the rapid peritoneal absorption of the fat escaping from the intestine seemed to have co operated in the production of the embolism It was noted once in 5 cases of fetal phosphorus intoxication, but in 13 cases of burns it was found 6 times He considers fat embolism an important factor in the fatal termination [illegible] bu [illegible] the liberation of the [illegible] favored by the simultaneous injury to the blood and lymphatic vessels, and also by the even momentary liquefaction of the fat by the heat.—*Munich Med. Woch.* from *Friedreich's Blatter*, No. 4.

Female Medical Inspector at Bombay.—The Bombayans, or some of them, have entered a complaint to the officials reflecting upon the action of a female physician and asking redress, by means of a considerable outlay of British gold, for an alleged desecration of one of their temples by her. It would appear, says the *Missionary Review*, that this physician, acting under a governmental appointment, had entered the temple in search of cases of plague. That the sensibilities of this people are very acute will be seen from the following quotation from their petition, which says: "This lady, against our most serious remonstrances, entered into the temple and desecrated the same and rendered it unfit for worship and for other religious purposes for which the same was established. By the aforesaid unlawful conduct of the said lady, your petitioners and their coreligionists have suffered considerable mental affliction, and their religious sensibility has been rudely and unnecessarily disturbed. Your petitioners further state that the efficacy of the said temple as a place of worship and religion having been destroyed by the desecration aforesaid, it will cost a considerable sum of money to celebrate the ceremonies and perform the religious rites necessary to purge the said temple from its desecration aforesaid, and to make it available again as a place of worship and religion, although not in their pristine state."

Professional Liberty and Practical Puericulture were the subjects treated at the recent Italian State Medical Congress at Venice. The absurdity and dangers of placing hospitals and asylums in the hands of non medical political campaign workers were discussed and the constant restrictions of the professional liberty of the physicians in charge, and physicians in general, described and denounced. A committee was appointed to investigate the subject and suggest means to remedy the existing conditions, which in many cases tend to defeat the objects for which the institution was founded. Massalongo described the way in which infants are sacrificed to inherited traditions and prejudices by the ignorant agricultural class, kept in a dirty bed in a smoky corner of the kitchen, all the light and air entering by a single door, the floor, the damp, trodden earth, covered with the excrements of domestic animals. The infant remains there a large part of the day, if not all the time, fed with extreme irregularity, the doorshut "to keep out the cold in winter, the heat in summer." The modern bacteriologist could not imagine a better culture for infective germs of all kinds. "Dirt seems to be one of the conditions of the existence of the contadini; a bath, sponging off with cold water, is in their opinion the cause of every ill." Even the better classes are ignorant of infant hygiene. He urged a rigorous propaganda on the part of physicians, citing what has been accomplished in France where the Roussel law, vigilant inspection and supervision of nursing children, assistance of mothers during pregnancy and confinement and penalties for desertion and maltreatment, are already accomplishing remarkable results in diminishing infant mortality and raising the physical standard. He recommended the establishment in each province of a committee for the protection of nursing children with a sanitary inspector and assistants who would instruct the people in the principles of practical puericulture, and also suitable legislation.—*Gazz. d. Osp. e d. Clin.*, September 18.

Superintendent Can Contract.—In the case of the Mt. Wilson Gold & Silver Mining Company vs. Burbidge, brought by the latter party against the former, there was evidence that when a certain miner in the employ of the company was hurt, the general superintendent had him taken from the mine to the mill, and ordered him taken from there to town. No witness stated that the superintendent ordered him taken to the plaintiff's (Burbidge's) hospital, but it was in evidence that the superintendent was at the hospital the next day, and told the plaintiff to take good care of the man and it would be all right. This evidence, the court of appeals of Colorado thinks, was sufficient to justify a finding that the services of the plaintiff were rendered at the request of the superintendent. After further stating that this miner, while in this mining company's employ, was injured by machinery which the latter's superintendent was engaged in operating for it, and that his injury required attention, the court says that it does not think that his removal to the hospital and his nursing while there, were so disconnected from the mining company's business as to be outside of the presumptive authority of the superintendent. As to the company's order that no more bills of that kind should be paid, after paying some of the bills occasioned by the injury, among which was the carriage bill, the court says that the fair inference from this is that before the order was made the superintendent had authority to contract such bills, and that the order was intended as a revocation of that authority; that as the order was issued after the carriage bill and the other bills to which it had reference were contracted, it was to be presumed, nothing appearing to the contrary, that it was issued after the services of the plaintiff were engaged; and that, the plaintiff having been suffered to nurse and care for the injured man until he was cured, without being notified of the order and relying on the responsibility of the company, its failure even to make an attempt to rebut the presumption of its superintendent's authority, inasmuch as the facts were in its possession, amounted, under the circumstances, to an admission that he was possessed of the necessary power.

Cervantes as Patient and Physician.—A recent medical thesis, accepted by the University of Paris, had for its theme the medical aspects of the life of the immortal Spanish author, from which the *British Medical Journal* has culled not a few interesting facts, among which is the tradition that Cervantes both studied and practiced the healing art. He was born in October, 1547, passed a life full of ill health, suffering and misfortunes of every kind, and died on April 23, 1616. He contracted malaria during a visit to Rome early in life, and on the very morning of the famous battle of Lepanto, Sept. 7, 1571, he was so ill with ague, that the captain of the vessel on which he served tried to induce him to remain below. He insisted on fighting, however, and received three arquebuss wounds, two in the chest and one on the left hand, which was permanently disabled. He was six months in hospital at Messina, and his wounds were yet incompletely healed when four years later he was made prisoner by Algerian corsairs on the high seas, Sept. 26, 1575. For five years he was held captive by the Moors, suffering much ill usage at their hands, but at last forcing them, out of fear of the influence which his indomitable spirit gave him among his fellow prisoners, to set him free. He died of dropsy, probably of cardiac origin, but there is really no evidence on the point. There is a tradition that Cervantes studied medicine, and there are in his works many passages which show that he had a considerable acquaintance with the art of healing as it was understood in his day. During his Algerian captivity he ministered to the needs of his fellow-prisoners in sickness with a skill which bespeaks, if not special training, a considerable experience in dealing with disease. How close and accurate an observer he was is shown by the wonderful picture of delusional insanity which he gives to "Don Quixote." The writer of the thesis points out that he anticipated Pinel in the rational treatment of insanity. The books of chivalry which disordered the brain of the Knight of the Sorrowful Countenance are destroyed, and every effort is made to create a new environment for him, his very delusions being skilfully taken advantage of to this end. It is somewhat strange that the writer should have made no reference to Sancho Panza's famous physician, who, in his strict view as to diet, may perhaps be looked upon as the scientific forerunner of Sir Andrew Clark He quotes, however, an apothegm that the "stomach is the laboratory in which health is manufactured," which shows that Cervantes had very sound views as to the important relations of the digestive to the other functions of the body

Amber in Medicine—The ancients employed amber as a medicine, and it is still prescribed by physicians in France, Germany and Italy Several chemists in Paris keep it constantly in stock It has been worn by ladies and children from time immemorial as an amulet, sometimes carved into "amphoræ," and has been pronounced of service either taken internally or worn around the neck Callistatus gave the name of Chryselektron to amber of a clear golden color, which, worn round the neck, cured ague, ground up with honey and rose oil, it was a specific for deafness, and with Attic honey, for dimness of sight But to come to more recent times, Pereira says in the third edition of his "Materia Medica," published in 1853, that amber was not even then employed as a medicine in this country, but that "it was formerly used in chronic catarrhs, amenorrhea, hysteria, etc, and was given either in the form of a powder, in doses of ten grains to a drachm, or in that of a tincture, a formula for both which is contained in some of the European formularies An old book by the chief pharmacist of Louis XIV of France has this paragraph "What I say may perhaps seem strange to those who do not know the great use there is of amber in China and among the savages, as well as in Europe, but the greatest consumption of it is in Austria, Germany and Poland, and in the neighborhood of Venice, and the Venetians were the first that brought it into such a vogue and fashion thereabout, there being few people in Lombardy, or along the Po, but wear amber necklaces, believing they keep them from quinzies and other ill effects of the neck and throat to which they are very subject by reason of the bad waters they are forced to drink in those parts Besides the great use of yellow amber for trinkets, it is of some use, too, in medicine, in the form of troches made from the powder, and which are given to restrain the spitting of blood and to stop dysenteries and the like Dose from ten to to thirty six grains in an appropriate vehicle, also from powder of amber with spirit of wine is drawn a yellow tincture endowed with a great many good qualities, especially in apoplectic and epileptic fits and paralytic cases, taken from ten drops to a dram in any agreeable liquor"—*Chemist and Druggist*, January 29

Denver

Dr F E Waxham has removed to Chicago The Denver and Arapahoe Medical Society has unanimously elected Dr Waxham an honorary member

Dr Hobart E Warren was appointed to the chair of Anatomy in the Denver University, vice Dr C D Spivak, resigned.

Dividends—The Denver committee of arrangements of the A M A has not only accomplished its work in a most satisfactory manner, but its finishing touches startled all the contributors to the fund, when they received dividends amounting to one third of their contributions After having distributed the dividends, Dr J T Eskridge, the treasurer, found himself encumbered by a residue of $264 54, which sum was donated to the Colorado Medical Library Association

Detroit

Bureau of Public Health—At the last meeting of Wayne County Society the question of the bureau of public health came up for consideration Dr C Henri Leonard stated that as Mr Corliss, the representative from Michigan, had practically killed the bill for the establishment of a bureau of public health, which had been presented at Washington, and which had been endorsed by every medical society of importance in the United States, including the American Medical Association, he would move that a committee of three be appointed by the president, whose duty it would be to sound the candidates for the House of Representatives and inform the medical profession in Michigan which of the candidates favored the proposed bill This man should receive the support of the entire profession, irrespective of party The motion was seconded and carried, and a committee will be appointed by the president in accordance with the wish of the society

Health Report for week ending October 15 Deaths 79, under 5 years 28, births 61, male 29, female 32, diphtheria 7, new cases 11, 6 recovered, 2 died, 10 remaining sick, scarlet fever 8, new cases 5, 1 recovered, 1 died, 11 remaining sick, smallpox 4, 4 remaining sick

The proposition to amalgamate the Wayne County Medical Society and the Detroit Medical and Library Association has fallen through The committees from the two societies for the purpose of considering this subject, came to the conclusion that, as both societies were incorporated under the laws of Michigan, it would be impossible to vote themselves out of existence without the unanimous consent of the members of both societies This, of course, was out of the question, so the executive officers of both societies concluded to drop the subject

Philadelphia

Cannon Fired by Students—On the night of October 7, some students of the University of Pennsylvania hauled a cannon into the doorway of Houston Hall and fired a heavy load which awaked the neighbors for miles around besides arousing the patients in the University Hospital to a high state of excitement and breaking nearly every window in the front part of that building A 'Student Committee," composed of the presidents of the classes, has decided to make a thorough investigation and are now making requests for all those who participated to come forward and pay for the damage to the buildings Those who confess and pay up will not be censured, but any offender who may subsequently be found will be turned over to the faculty to be dealt with in a summary manner

The Blood of Typhoid Patients—Since Woodward first originated the term "typho malarial fever," the profession has been much interested in finding out the percentage of cases of typhoid fever which may be complicated with malaria Abundant opportunity has recently been furnished from the fact that so many soldier patients have been brought to this city from infected areas of the south While report of the work done at the Pepper Laboratory has not been made public, it is stated that enough is known to justify the assertion that the two diseases *may* exist concurrently Several months may elapse before this work will be entirely completed

Mortality—The number of deaths for the week ending October 15 was 331, a decrease of 77 over the previous week and of 53 over the corresponding period of last year The principal causes of death were Alcoholism, 2, apoplexy, 13, nephritis, 17, cancer, 11, cholera infantum, 6, tuberculosis, 38, croup, 6, diabetes, 4, heart disease, 24, inanition, 12, pneumonia, 13, appendicitis, 4, marasmus, 18, old age, 15, suicide, 3, tetanus, 1, uremia, 4, whooping cough, 7

Infectious Diseases—This week Diphtheria, 115 cases, 21 deaths, scarlet fever, 18 cases, 1 death, typhoid fever, 200 cases, 11 deaths Last week Diphtheria, 107 cases, 22 deaths, scarlet fever, 25 cases, typhoid fever, 162 cases, 14 deaths

Dr White Resigns—Dr J William White, Professor of Clinical Surgery in the University of Pennsylvania, has severed his connection with the surgical staff of the Philadelphia (Blockley) Hospital, to which he was elected in 1892 It no doubt is a source of much regret to Dr White to sever his relations with this time honored institution, yet the new duties devolved upon him at the University made such action compulsory Owing to the continued illness of Dr John Ashhurst, Dr White will have entire supervision over the clinical material during the coming term The unsurpassed clinical material afforded by the Blockley Hospital makes the membership on the staff a coveted one both on the part of the recipient and also on the part of the University of Pennsylvania, which has all the privileges and advantages offered by this hospital Dr Charles Frazer, a nephew of Provost Charles Harrison, will doubtless succeed Dr White on the surgical staff of Blockley, but no definite action will be taken in the matter until the next meeting of the Board of Charities, to be held next month

PENNSYLVANIA HOSPITAL CLAIMS PRIORITY —Since the war is now over and the soldiers are being cared for in well equipped hospitals all over the land, the question has arisen as to the first one to volunteer its services after the call to arms While the *Medico Chirurgical* and *University Hospitals* have been most active in bringing the sick soldiers to this city, another hospital here produces proof of its priority in this matter A letter of Dr Thomas G Morton to Surgeon General Sternberg dated April 21, has been printed in one of the daily papers here, and serves to justify this claim

COMPULSORY VACCINATION —The Board of Health, after making investigation of the manner in which vaccination is being avoided by the children in the public schools of the city, have recently sent out a printed circular to all of the authorities of the different schools, calling attention to the following Act of the Assembly approved in 1895, as follows "All principals or other persons in charge of any public, private, parochial, Sunday, or other schools are hereby required to refuse admission of any child to the schools under their charge or supervision except upon a certificate signed by a physician, setting forth that such child has been successfully vaccinated or that it has previously had smallpox" Violations of this law will be summarily punished by the Board of Health

MEMORIAL GATEWAY —A committee has been appointed for the erection of a suitable memorial to all soldiers of the University of Pennsylvania who participated in the late war It will be remembered that one graduate lost his life early in the struggle, and the name of Osgood still lingers in the memory of all the alumni, while the unfortunate death of Surgeon Gibbs, soon after the first landing was made on Cuban soil, makes this memorial all the more appropriate To this end a large number of the Alumni Association of the University will be appointed to raise sufficient money for the erection of a memorial gateway at the entrance of the college campus at Thirty Fourth Street and Woodland Avenue

A SAILOR DEAD —The United States officials at the quarantine station on Reedy Island, near here, were recently apprised of the death of a sailor which occurred on the steamship *Banan* while in transit from Port Antonio to this city Subsequent examination proved that the cause of death was due to yellow fever The steamship had on board 15,000 bunches of bananas, which will doubtless be destroyed As the authorities have recently established a quarantine station for the purpose of guarding against the introduction of this disease, all of the necessary precautions will be taken against this vessel and members of the crew In order to prevent the possibility of the spread of the disease from this case the vessel was ordered out to sea to bury the body of the unfortunate sailor

NEW CHILDREN'S HOSPITAL – At a meeting held recently in Germantown, the public spirited citizens of that place organized for the purpose of erecting a children's hospital in that district of Philadelphia Dr Thomas Brockbank was elected president and Dr H Van Buren secretary It is proposed to model the hospital after the St Christopher Children's Hospital

CHARITY BEQUESTS —The will of Henry Pfander, which was admitted to probate recently, makes the following bequests to charity To the Jewish Hospital Association, $2000, Jewish Foster Home and Orphan Asylum, $2000, Jewish Maternity Association, $1000, Society of the United Hebrew Charities, $1000 Several other charitable bequests are made

WITHOUT A LICENSE —According to one of the papers here, a man by the name of H P Gorman of Philadelphia, was arrested at Carlisle, Pa, on October 3, for practising medicine without a license, and failing to give bond, was committed to prison, where he will remain until the November term of court

LECTURES IN SURGERY —Owing to the continued illness of Dr John Ashhurst, professor of surgery at the University of Pennsylvania, Dr H R Wharton will give the didatic lectures this year to the graduating class, under the supervision of Dr Ashhurst Dr Wharton has been assistant to Dr Ashhurst for several years, and is author of a work on minor surgery

ENSIGN POWELSON —Ensign Powelson, while on board the *St Paul*, was recently injured by the breaking of an elevator, and was taken to the Episcopal Hospital, where he will remain for several weeks, after which he will return to his home in New Jersey

VERDICT OF $3500 —At Morristown, adjacent to Philadelphia, a blacksmith by the name of William Force was recently awarded damages in the sum of $3500 against his attending physician, Dr Harvey F Scholl, for improper treatment rendered to a fractured leg

Washington

HEALTH OFFICER WOODWARD SUSTAINED —The health officer recently found it imperative to inform the Commissioners of the District, that the Freedman's Hospital authorities were violating the contagious disease regulations, that they had recently turned away a case of diphtheria from the institution and had not notified the Health Department, as required by law, of the existence of such a case The Commissioners referred the matter to the Secretary of the Interior who, in reply, transmitted a copy of the report submitted to him by the Board of Visitors to the Hospital, in which the Hospital authorities claimed to have erred in the matter through misconception The Secretary added "The attention of the Surgeon in charge of the Hospital has been called to the dereliction of duty complained of and, in the future, he will strictly comply in every respect with the requirements of the law"

SURGEON GENERAL STERNBERG'S REPLY —The following reply was sent by Surgeon General Sternberg to the Commission investigating the conduct of the war "The number of medical officers allowed by law is inadequate in times of peace The total number allowed is 192 There are at present 13 vacancies The administration of the surgeon general's office and Army Medical Museum requires 6 Eleven are on duty at medical supply depots and as chief surgeons of military departments One is at the Soldier's Home, 56 are at general hospitals, on hospital ships and at garrisoned posts Four have been disabled since the commencement of the war by sickness Five are on duty as chief surgeons of army corps This leaves 97 medical officers available for duty with troops in the field Of these 35 have been appointed brigade surgeons of volunteers and are distributed among the various army corps Since the declaration of war, the loss by death has been 2, and 23 are now absent from duty on sick leave This deficiency in regular medical officers has made it necessary to employ more than 650 contract surgeons Most of these doctors from civil life are doing good service, and many of them are thoroughly well equipped physicians and surgeons, with ample hospital experience, but it has been impossible to make a careful selection owing to the great pressure of business in the Surgeon General's office, and the urgency has been so great that it has not been practicable to have examining boards pass upon their qualifications I have endeavored, so far as possible, to obtain satisfactory professional indorsement before making a contract with an applicant The number of applicants have been so great and the personal visits of applicants and their friends so numerous, as to constitute a serious embarrassment in conducting the business of my office *In addition to this, there have been* appointed by the President eight corps surgeons, with the rank of lieutenant colonel, 24 division surgeons, with the rank of major, and 86 brigade surgeons, also 3 medical officers for each of the regiments of the United States infantry, cavalry and engineers All voluntary regiments have 3 medical officers appointed by governors of States Referring to the alleged deficiency of medical officers with the Fifth Army Corps at Santiago, I would say, that this Corps, upon leaving Tama, had with it 36 regular medical officers and 20 contract doctors, a total of 71, or over 4 per 1000 of the strength of the command, which, I was informed, was about 16,000 Additional medical assistance was sent by the hospital ship *Relief* which arrived at Siboney July 7 with 20 doctors aboard There was also some volunteer assistance by Dr Lesser of the Red Cross Society, Dr Rudberg of the Swedish Navy and several surgeons of the navy from ships in the vicinity It has not been the expectation of the medical department that every wounded man would immediately receive the attention of a surgeon No modern army makes provision for so large a number of medical officers as this would require But attached to our army there is a corps of non combatants, known as the hospital corps, which is the *organized and authorized Red Cross of the* army *At the* outbreak of the war we had 1800 hospital corps men in service At present there are more than 6000 These men wear a brassard upon the left arm, bearing the red cross of the Geneva Convention We have done our best in instructing them to give first aid to the wounded, and in the majority of cases a first-aid dressing properly applied by one of these men is all that is required All of the surgeons who have come from the front have testified to the remarkable results obtained from the prompt application of aseptic dressings by our hospital corps men and by the soldiers themselves, or their comrades The proper application of the dressings contained in the first-aid packet, which is carried by every soldier, is, under existing regulations, a matter in which every enlisted man has special instructions For some time past this instruction has been given, first by our medical officers to the company officers, and by them to the enlisted men "

Health of the District —The report of Health Officer Woodward for the week ended October 8, shows the total number of deaths to have been 111, of which number 63 were white and 48 colored There were 155 births reported, 102 white and 53 colored At the close of the week there were 115 cases of diphtheria and 79 cases of scarlet fever under treatment

Medical Society —At the meeting of the Medical Society held on the 10th inst, Dr Lamb presented the specimens and gave the history of a, valvular disease of the heart, b, a specimen from the brain showing old and recent hemorrhage and c, fracture of spasmodic origin of the sesamoid bone of a horse Dr Armstrong Hopkins addressed the Society on medical and surgical work in India She described her personal experiences while connected with the British hospitals, and as a missionary physician from the United States, and gave an account of the habits, religion, customs and racial peculiarities of the people of India, closing with an amusing account of a professional visit to one of the harems of a local King, where she met in consultation with six local practitioners Dr A F A King delivered an eulogistic address on Dr George Byrd Harrison, a deceased member of the Society Dr Frederick reported resolutions on the death of Dr Drawbaugh

Nurses' Guild —The organization of nurses known as the Guild of St Barnabas for Nurses, has just completed a three days' convention in this city Their *special object is to secure* a home for nurses in Washington and they have opened a temporary register for nurses at the Central Dispensary and Emergency Hospital The *following* physicians were elected to honorary membership Drs Shands, Mundell, Tompkins, Morse, Burnette, Hawkes, Carr, H L E Johnson, J T Johnston, *Hickling, Portman, Hiberger,* Rixey (*U S A*), *T* R Stone, Fox, Dufour, Robin, French, A A Snyder, Maddox and V B Jackson

Societies

The following recent meetings are noted

Connecticut —Semi annual of the Hartford County Medical Association, October 19

Illinois —Chicago Medical Society, October 12, Fulton County Medical Society, Canton, October 1, McDonough County Medical Association, Macomb, October 4, McLean County Medical Society, Bloomington, October 6

Kansas —Golden Belt Medical Society, Solomon, October 7

Kentucky —Clark County Medical Society, New Albany, October 4

Massachusetts —Hampden District Medical Society, October 18

Michigan —Grand Rapids Academy of Medicine, October 3, Wayne County Medical Society, Detroit, October 6

Minnesota —Crow River Valley Medical Association, Litchfield, October 6

Missouri —St Joseph Medical Society, October 11, St Louis Medical Society of Missouri, October 15

New York —Albany County Medical Society, Albany, October 10, Associated Physicians of Long Island, Patchogue, L I, October 8, Monroe County Medical Society, Rochester, October 6

Ohio —Muskingum County Medical Society, Zanesville, October 13

Pennsylvania —Luzerne County Medical Society, Wilkesbarre, October 5, Susquehanna County Medical Society, New *Milford, October 4*

Utah —State Medical Society, Salt Lake City, October 7

Wisconsin —Rock County Medical Society, Janesville, October 7

THE PUBLIC SERVICE

Sanitary Measures Against the Spread of Typhoid Infection in Camps —Surgeon General Sternberg has sent a communication to the chief surgeons of the troops in the field, commending it to their careful consideration and as of value to them in their efforts to limit the spread of typhoid fever in their commands In his letter transmitting this communication, he says that where the conditions are not entirely satisfactory for digging sinks of the proper depth, the recommendations of the Board should be adopted, and water tight troughs, as suggested, be used He invites special attention to the recommendation of the Board that "every *opportunity should* be taken to expose blankets and bedding to the sunlight," and states that infected tents, *clothing* and *bedding* should be disinfected by steam, by boiling water or by a 5 per cent solution of carbolic acid

The communication and its endorsements read as follows *The Board of Medical Officers* convened per *S O 194*, par 40, c s, A G O, Washington, D C, Aug 18, 1898, to inquire into the causation and spread of fever in the camps in the United States, beg to make the following *provisional report*

Although we are not as yet ready to come to a definite conclusion concerning the causation and means of spread of this disease, we feel quite thoroughly convinced that *the fly has* been an important factor in its dissemination We are also convinced that so long as the present method of disposing of fecal matter in the camps is continued it will be quite impossible *to* eradicate this disease *We believe that the bacilli* are now being daily disseminated by flies and that *the tentage,* bedding and clothing of the soldiers have become more or less infected with the germs of typhoid fever and we think that radical steps should be taken to destroy this infection Until this is done we are convinced that changes of camp sites will be of little or no avail We therefore feel called upon at *present* to make the following recommendations pertaining to this matter

1 We recommend that the sink be universally and wholly replaced by the following contrivances Each regiment should be furnished with three wooden boxes lined with galvanized iron and made perfectly water tight Each of these boxes is designed to serve as a battalion sink, the dimensions of each box should be as follows—length *fourteen* feet, width two feet depth eighteen inches This box should be set at a slight incline, so that one end will be two to four inches lower than

the other end If possible, there should be placed over the upper end of each box a water tap, this can only be done when water is piped into the camps When this is not feasible, water will have to be poured into the trough The lower end of this trough should have a three inch opening with a conductor leading outside the house and opening over a pit or well The box end of this opening should be guarded by a tube of the same diameter and about fourteen inches high, with a curved handle at top, by means of which it can be lifted For use each of these troughs should be filled to a depth of six inches with a 5 per cent solution of carbolic acid or, to be more definite, there should be placed in each box one hundred gallons of water and five gallons of crude carbolic acid This mixture should be thoroughly stirred The feces and urine of all the men should be received into the trough, the box being provided with a suitable cover having twelve openings A metallic trough of proper height, leading into this larger trough, may be constructed at each end for urine Once or twice a day, as may be necessary, the contents of this box should be allowed to run into the sink or well and the material should then be immediately covered freely with earth

Where lime has already been supplied to the camps as a disinfectant, milk of lime may be used in these boxes instead of the 5 per cent solution of carbolic acid, and when this is done one quarter of a barrel of lime should be mixed with the one hundred gallons of water and thoroughly stirred A similar privy of less capacity should be prepared for the officers and cared for in the same way

The care of these privies should be made a duty of the medical officer of the regiment, and he should be held responsible for their proper condition

We are convinced that typhoid fever will not be eradicated until the stools and urine of every man are thoroughly disinfected Proper utensils with sufficient soap and water should be provided at each battalion sink, such as we have described, and every man should be required, in the presence of a sentinel, placed there for that purpose, to thoroughly wash his hands on leaving the sink

2 We believe, as already stated, that the tentage, the floors of the tents and personal clothing of the soldiers, are infected and should be thoroughly disinfected The tents may be boiled It would be preferable to establish at each of the large camps a steam plant where the tentage and all clothing should be thoroughly disinfected The flooring of the tents should be scrubbed with a 5 per cent solution of carbolic acid and exposed to the direct rays of the sun for at least twelve hours We have found many soldiers sleeping on old, dirty mattresses, these should be burned Many infected regiments have been mustered out and their tentage and blankets turned in Before these are issued they should be thoroughly disinfected

Every opportunity should be taken to expose blankets and bedding to the sunlight, our inspection of various camps has convinced us that sufficient attention is not paid to this

In the opinion of the Board, no time should be lost in the inauguration and rigid enforcement of these measures Otherwise we are firmly convinced that typhoid fever will continue to prevail until late fall at least Moreover, even after the fly is paralyzed by the cold weather, the infected bedding and tentage will cause a continuance of the disease

Very respectfully,

[Signed] Walter Reed,
Major and Surgeon, U S A

[Signed] Victor C Vaughan,
Major and Division Surgeon U S V

First Endorsement

War Department—Surgeon General's Office,
Sept 30, 1898

Respectfully referred to Lieut Col Charles Smart, Deputy Surgeon General, U S Army, for remark

[Signed] Geo M Sternberg,
Surgeon General, U S Army

Second Indorsement

War Department—Surgeon General's Office,
Oct 1, 1898

Respectfully returned to the Surgeon General of the Army

The experience of the Second Army Corps during the past two months does not sustain the Board in its assertion that until radical steps have been taken to destroy infection, changes of camp site will be of little or no avail Troops, in removing from an infected site to new ground, carry with them only the infection in men in the incubatory stage Tents, clothing, blankets, etc, are disinfected by exposure to sun and air on the new ground Cases developed in infected men can be removed to hospital, and in ten days or two weeks the command will be practically free from the disease, and when camped on fresh ground will remain free from all except sporadic cases if the camp has proper sanitary government This includes supervision of the food, water supply, clothing, personal cleanliness and cleanliness of the quarters of the men, with a sufficient area in quarters, and with a flooring high enough to give free circulation of air in the sub floor space

If the sinks are 150 yards from the quarters of the men, each company sink 14 feet long and of proper depth, and the deposits regularly treated with lime and dry earth, disinfection of the excreta will be effected as satisfactorily as if previously mixed with the disinfectant material in a trough as specified

The medical officer should not, in my opinion, be held responsible for the proper condition of the privies This is the duty of the police officer—the officer of the day The duty of the medical officer is to bring insanitary conditions to the notice of the commanding officer and to make suggestions for their remedy

If change of camp site is not effected, all efforts at disinfection of clothing, blankets, tents, etc, will be unavailing, if the change is effected, disinfection other than by free exposure to sun and air will be unnecessary except in special instances of known soiling by typhoid discharges

[Signed] Charles Smart,
Deputy Surgeon General, U S A

CHANGE OF ADDRESS

ORIGINAL ARTICLES

INFANTILE TUBERCULOSIS

Presented to the Section on Diseases of Children, at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo , June 7-10, 1898

BY LOUIS FISCHER, M D
Professor of Diseases in New York School of Clinical Medicine Physician to Messiah Home for Children Attending Physician to Children's Department of German Poliklinik and to Children's Department of the West Side German Dispensary Consulting Physician, Diseases of Children to the United Hebrew Charities, etc
NEW YORK CITY

A very large number of tuberculous children seen in the course of the last ten years is my excuse for attempting to bring this subject before your honorable body for discussion This subject is handled in a masterly manner in the text-book of Professor Baginsky, and I shall therefore follow his classification

There is certainly a decided relationship existing between scrofulosis and tuberculosis, and thus most distinguished pediatrists believe the two diseases to be identical with one another In fact, in studying the large number of cases of scrofulosis seen by me, it is more and more apparent that this disease is the stepping-stone to tuberculosis, and that one is the result of the other In former years the text books speak of the scrofulosis diathesis, and this latter condition we today recognize as the pre-tuberculous condition The infant at birth that is put on an improper food is certainly a good subject for the development of rachitis and scrofulosis In other words, the predisposing cause is certainly, in my opinion, greatly due to faulty nutrition, bad, foul smelling, poorly ventilated apartments, and add to them all other factors which are combined in the words, "poor hygiene," then it is very easy to understand why a simply acute bronchitis and an otherwise mild form of whooping-cough will persist for months and ultimately develop tuberculosis The two diseases which are most easily followed by tuberculosis are whooping-cough and chronic summer diarrhea

There are very few today that deny that tuberculosis is caused by a specific bacillus, discovered by Robert Koch The infectious character of this bacillus has so often been demonstrated, especially in adults, that we can also assume that this disease can be transmitted directly from parents to their children the mode of transmission being usually by means of the sputum coughed up and allowed to dry in the apartments where children sleep These live microorganisms can, by being inhaled, cause direct infection through the air-tubes We, therefore, regard this disease as an acute specific infectious disease, infection brought about by the introduction of the tubercle bacillus into a usually weakened or subnormal body with little resisting power, and hence the tubercle bacillus finds its proper soil, develops and infects and spreads until we have from a small focus in the beginning, a very largely distributed disease The method or the way in which a patient contracts tuberculosis is so simple that it merely requires a word, recognizing, as we do, the infectious nature of tuberculosis, it requires but the dried sputum in the house of a tuberculous patient to transmit the bacilli through the air, which will lodge in the pharynx, possibly the larynx, and may even be carried lower down into the bronchi or alveoli, and in this manner enter and infect the lung

The interesting studies of Cornet in regard to the transmission of tuberculosis are worth noting How seriously this should be considered can be learned when we study the case reported by Wassermann (Virchow Archiv), quoted by Professor Baginsky, in which a child six weeks old was infected with tuberculosis by coming in contact, in the same room, with a tuberculous man for only eight days Lehman (*Berlin Klin Woch* 1894, Nos 26 and 28) details a series of six children that had been accidentally infected by intrauterine inoculation This must, however, be carefully considered before accepting isolated cases as definite results Baginsky quotes a child from his experience, in which a tubercle nodule was transmitted by infection on the eyelid followed by suppuration This was accidentally transmitted to the child from a tuberculous person Demme, in the *Jahresbericht* of the Jenner Children's Hospital in Berne, 1889, and Deneke, in the *Deutsche Med Woch* , 1890, p 13, discusses a series of children wherein tuberculosis was accidentally transmitted by means of bandages applied by tuberculous people

That tuberculosis can be transmitted by the agency of raw milk from tuberculous cows is certainly not questioned, still it is surprising to note that even Koch does not always believe this to be the case Boiling the milk suffices to destroy all means of infection Demme reports an instructive instance in which a trained nurse suffering from lupus, transmitted and infected tuberculosis in children by means of handling their nourishment When tuberculosis speads, it attacks every part of the body, so that none can be considered safe from its invasion Many authors, among them Doutrelpoint, Lustig, Meisles, and Stricker, have found the bacillus in the blood and in the walls of the blood-vessels It can also be found in the skin, where it forms irregular ulcerations or lupus Demme has found the bacillus in the pus from an otitis He also found the bacillus in the discharge exuding from eczema Tuberculosis frequently attacks primarily the thymus, the heart, the pharynx and the peritoneum Enteritis with tuberculous ulcerations opening spontaneously have been *frequently reported* by Baginsky The numerous tuberculous joint affections with the suppurations of the bones are usually of a tubercu lous nature Weigert believed, in a report made to the *Gesellschaft fur Kinderheilkunde*, that the liver was a sort of receptaculum for this tuberculous virus, The acute form of general miliary tuberculosis is described by the French authors, Empis, Landougy, Aviragnet (Thése de Paris, 1892, de la tuberculoze chez les enfants, chapter 6, typho-tuberculosis) This is a masterly contribution to the subject of tuberculosis and will repay reading it The so called mixed infections are very hard to diagnose, unless we form a true clinical picture by these interesting observations

Diagnosis —The diagnosis of these diseases in infancy and childhood is by no means simple In fact, it is extremely difficult, and can frequently be made by a process of exclusion It resembles mostly typhoid fever, from which it can easily be differentiated by the absence of the diazo reaction Baginsky states that we must not rely upon the ophthalmoscopic examination, for the absence of tuberculosis in the choroid does not speak positively against depressence of miliary tuberculosis He furthermore states that knowing the dangers of tuberculin injections in children, he warns against using the same for arriving at a positive diagnosis The prognosis of localized tuberculosis is certainly good, especially so if radical surgical measures are instituted It has also been proven, and postmortem examinations have fortified this clinical fact, that cheesy infiltrations in the lungs have been cured Diffuse tuberculosis is, however, certainly fatal

Cases of meningitis have frequently been reported as cured by Fleischman and others This fact is doubted by equally *prominent* observers Professor Baginsky declares that he has never seen a child recover from tuberculous meningitis In my experience one child has certainly been greatly improved, although I do not believe that the disease is competely arrested I firmly believe that under the influence of treatment, many symptoms otherwise prominent are now latent, and the child's improved condition depends on the same It will take years of careful, close scrutiny to thoroughly test a single child with this terrible cerebral form of meningitis, before deciding whether it is really cured or otherwise

Less than three years ago I published a paper on the treatment of pulmonary tuberculosis, based on a series of cases which I attended in the children's department of the New York Post-Graduate Medical School and Hospital (*New York Medical Journal* for Aug, 17, 1895) One of the children herein reported was 2 years old at that time This case was reported by me at that time at the Post Graduate Clinical Society, during a discussion of Dr Crooks' paper on the value of creosote treatment in tuberculosis It was really instructive to have this case report every Monday at my clinic, and to be able to demonstrate on a patient (what we have always wished for) theoretically

Pulmonary tuberculosis frequently manifests itself without a cough, and if a cough be present without any expectoration, then we have a very different clinical picture in a child from that in an adult suffering with the same disease We may have moist râles at times, a little harsh breathing and slight elevation of the temperature Frequently there are small areas of dulness in the lung, caused by either consolidation or from enlarged and swollen bronchial glands Then, again, I have seen cases of tuberculosis in which there have been no pulmonary symptoms on either percussion or auscultation, and where the clinical history was absolutely negative In a case of this kind which I recall, the diagnosis of tuberculosis was made when the child suffered from a prolonged attack of diarrhea An accidental examination of the micropurulent discharge from the bowels showed almost a pure culture of tubercle bacilli, and thus the diagnosis was established

The symptoms upon which we have relied chiefly in making a diagnosis have been loss of weight, disturbances with digestion, a slight attack of febrile malaria, besides constant irritability Such children will frequently show very slight, if any, pulmonary symptoms, so that the diagnosis must be made by a process of exclusion Such distinct diagnostic features as the presence of cough, expectoration and tubercle bacilli, dulness on percussion, with moist râles and night sweats, as we find them in the adult, are out of the question How often do we have children brought to us with a distinct history of intermittent fever, lasting several months, and it is only when we can trace such a case back to a former infection of measles, pertussis or pneumonia, or to an infection of influenza, that our attention is directed to the possibility of there being a case of tuberculosis before us Dulness on percussion over the thorax is so frequently due to enlarged bronchial glands that it must be borne in mind when suspecting consolidation, especially is this true in those forms of so called scrofular enlargement It is, therefore, to my mind not such an easy matter to diagnose a case of tuberculosis, and it is a safe advice to follow, "to observe a suspected case of tuberculosis for several weeks, and sometimes months before giving a positive opinion relative to either the diagnosis or more particularly to the prognosis in a given case" While speaking of the prognosis, it may be proper for me to say that it is always a wise plan not to commit yourself positively as to the outcome of any given case of tuberculosis, for frequently do we find a sudden hemorrhage appearing, which may end fatally in a short time, while our patient was apparently improving and giving us hope On the other hand, let us not lose sight of the fact that a great many cases of tuberculosis (with cavities) have been cured This has been proven by postmortem examinations many times This I mention in order to demonstrate the necessity for extreme care in passing judgment upon a given case My plan is never to call a case hopeless until I am positive that all means used for relief were hopeless

Dietetic treatment —The treatment consisted of supporting diet—giving a highly concentrated form of food in as small a quantity as possible Thus, eggs and milk and expressed meat juice, and the farinacæ are chiefly used When children care for it, I frequently advise buttermilk and all forms of fermented milk, white meat, chicken, fish and shellfish, or broth made from the above at frequent intervals So much for the dietetic treatment

Medical treatment —No drug that has ever been used has been found as efficacious as cod liver oil and creosote The former I usually give in a 25 per cent emulsion, and if the stomach tolerates it, I then increase gradually, giving a 50 per cent emulsion, and if I find this well borne then I try the pure cod liver oil, giving a teaspoonful to a child under 5 years three times a day If, however, the stomach will not tolerate cod liver oil, then I use it in the form of the bath, i e, by inunction My plan is to have the child's body sponged with soap and water, then dry the skin thoroughly with a coarse turkish towel and rub the child's body, chiefly the chest and abdomen, for about five or ten minutes every morning In this manner we can frequently have one ounce of oil absorbed into the circulation

Creosote is certainly par excellence, the only drug to be used in this disease While formerly we were restricted to the use of the ordinary beechwood creosote, within the last few years chemistry has given us the creosote carbonate To Dr Holscher of the Drei-Konigenhospital in Mulheim on the Rhine, belongs the credit of having discovered the value of this drug In a letter recently received by me from the Doctor, he reiterates his former good results, and states that Chaumier and others have given as much as 30 grams per day He also refers to the fact that Professor von Leyden reports giving from 5 to 25 drops of this drug three times per day

My own experience with creosote carbonate has been limited to between forty and fifty cases I usually give children of 1 year one drop, children of 5 years five drops three times per day In other words, one drop for each year until ten drops three times per day are given There is usually a marked increase in the appetite noticeable, and a decided improvement in the cough, if any is present Symptomatic treatment is not contraindicated, and urgent symptoms of whatever nature should be properly looked into

Alcoholic stimulation requires but one word namely, that if necessary alcohol should be used, but cautiously

Hygienic treatment—This, I consider to be the foundation for an ultimate cure if properly carried out No medicine can equal fresh air and sunshine and cleanliness The bulk of our cases seen in both dispensary and private practice occur in children living in tenement houses where just the conditions above mentioned are lacking In a paper recently read before the Society for Medical Progress, of our city, Dr W Freudenthal dwells especially on the importance of sunshine and ventilation, if we attempt to cure a given case of tuberculosis

I feel that I owe you a word of apology for attempting to speak on tuberculosis, especially in a region surrounded by climatologists and men whose lives have been spent in the treatment of tuberculosis But I feel that infantile tuberculosis, as we frequntly see it in cases which are diagnosed as marasmus and allied troubles, are cases of tuberculosis

187 Second Avenue

DISCUSSION

Dr Slacle of Minneapolis—I was pleased to find the Doctor in opening his paper stated the relation of scrofula to tuberculosis that it is considered the tubercular diathesis Two years ago, just the day before I was going to deliver a lecture on scrofula before the class, I received Dr Rotch's work, and I was surprised to find that the terms struma and scrofula were not in his work at all and no explanation anywhere I wrote to him in regard to it and he responded very kindly and courteously that in dropping those unscientific terms, scrofula, struma, colic, diathesis, etc , he was but following the suggestion of the American Pediatric Society It was a question with me whether it was prudent to drop those terms and whether it could be done by any one man—they have been used so long At any rate, it seems now that it is but a tubercular diathesis Yet I have a paradox to state, which makes me suspect that its nature is not thoroughly understood I have a large clientéle among the poor Russian Jews [illegible] prone to those local manifestations which we have been accustomed to call scrofula or struma Yet I have to state that it is a remarkable fact that they are comparatively immune from tuberculosis later on Something has been said about that by some foreign writers and there has been an attempt to explain it If we admit that the scrofula or strumous manifestations in early life make them immune later to tuberculosis, then we would have to deny what seems to be an established fact, that struma is but the tubercular diathesis In regard to Dr Fischer's treatment of tuberculosis in children, there is nothing to gain Undoubtedly it is a disease of malnutrition, and undoubtedly good hygiene and good nutrition are of very great value Undoubtedly the few remedies he mentioned creosote, nux vomica, cod liver oil and alcohol, are good remedies in well chosen cases In regard to cod liver oil, we find so many young children that do not digest cod liver oil that I have come to prescribe the maltine with cod liver oil, rather than the emulsions of cod liver oil, preferably the extract of malt with cod liver oil and hyposulphites

Dr H D Jerowitz, Kansas City—In reference to tuberculosis in children the fact is that very frequently a chronic pneumonia and a case of tuberculosis are easily confounded A great many so called cases of tuberculosis in children which recover are nothing more nor less than cases of chronic pneumonia or pneumonia in the third stage with pus or a pneumonia complicated with an empyema A number of these cases, as we see, are caused by measles or pertussis, by malaria or typhoid fever, and owing to the decreased vitality, the pneumonia, instead of passing on to the resolution, proceeds to the chronic stage, and during this time the case presents the usual appearance of a case of tuberculosis, lasting all the way from several weeks to as long as five or six months As a rule we think it is a case of tuberculosis that is beyond recovery, but the case gets well The only way I know of differentiation is with the microscope and that is not always practicable with young children We can not always get the sputum, and therefore in a great many cases it is often only a question of opinion as to whether it is a case of tuberculosis or pneumonia So it seems to me a great many cases of supposed cure in tuberculosis are only cases of cure of chronic pneumonia None of the remedies suggested are new One of the chief remedial agents, I consider, is fresh air The majority of these cases live in unhygienic and unsanitary surroundings

Dr Rosa Encelman, Chicago—It is a question to me whether the Doctor has thought of the ante fetal origin of tuberculosis, either through the sperm or an ovarian genetic origin Another factor to which I wish to call attention, is the possible origin through what I have been pleased to call a scrofulous vaginitis A great many patients come to me with what I believe to be a scrofulous vaginitis By "scrofulous" I mean, as one of the gentlemen has recently said, a predisposition Such children usually have chronic glandular enlargements and all the train of symptoms which cause us to make the diagnosis of scrofula

Dr Henry E Tuley, Louisville—I think the Doctor lays too much stress upon the presence of injury I recall distinctly one case that presented itself at my clinic There was no history of any heredity or injury The patient was decidedly anemic, very much emaciated, and had a considerable accumulation of ascitic fluid The mere suggestion of an operation caused the mother to withdraw the child from our observation About five months later the patient returned again to the clinic and was entirely changed in character During that time it developed that nothing had been done There was no trace what [illegible] scitic accumulation nor [illegible] ould lea [illegible] there had been a [illegible] I [illegible] self to the surg [illegible] int This was [illegible] at once, the family consenting to this The boy improved wonderfully in the next two months and has grown stout and strong About four months later, a year and a half from the first observation, he returned with a cough and emaciation and there is now involvement of the apices of both lungs and microscopic evidence of tuberculosis These cases present such peculiarities that it seems to me the importance of the variety of symptoms should be impressed upon us Another thing the Doctor mentioned in passing is the presence of a subnormal temperature in tuberculosis I would disagree with him in regard to that, having made observations in several cases, one especially, which I reported with a forty days' record of the temperature, with a high temperature each day, never reaching normal for several weeks before the signs were present in the chest, the child finally dying of a tubercular pneumonia, the autopsy proving the diagnosis I think more often these cases have high temperatures than they have subnormal or low ones

Dr **McConnel**, of Kansas—With children, especially, it is very difficult to continue for any length of time the internal administration of any preparation of cod liver oil, in emulsion or any other form Inunction I have found a very useful method of using cod liver oil It can be applied twice daily over the abdomen and chest of the child, and the child will tolerate it better that way often than in any other way Dr Lawrence mentioned rarely finding the condition in males and also rarely finding it idiopathic I wish to mention a case of a young man with tubercular peritonitis, the origin of which was traced to an injury received from a fall off a bicycle That is the only instance I have encountered in which it came in that way About ten weeks previous to this case applying for medical aid, the boy gave a history of having fallen from a wheel and struck on the right handle of the bicycle in the right iliac region The pain was so violent that he said he fainted and was unable to stand or walk for several minutes From that time his health began to decline, his appetite failed and he became emaciated, thin and anemic His parents became solicitous for his welfare and consulted several surgeons There was considerable diversity of opinion in regard to his ailment Some considered it peritonitis Until an operation was performed, the character of the case was not cleared up There had been a general peritonitis of the abdominal cavity, but the appendix was not involved The adhesions were many, both of the mesentery and the intestines A laparotomy was performed and drainage used, which greatly improved the child's condition That has been three months since, he is not well to day, but he has improved

Dr H B **Whitney**, Denver—In regard to Dr Lawrence's paper, I agree with him, especially as to diagnosis I think he has laid stress where it should be laid, especially on the pain where there is much emaciation, the slow development of ascites, and together with that it seems to me is very common the presence of masses of induration or irregular tumor masses here and there scattered over the abdomen These things have seemed to me to be of great importance in the diagnosis of tubercular peritonitis I would also like in this assembly to lay special stress on what seems to me to be an unquestionable fact, and that is the comparative immunity of children of tubercular parents here in Colorado I merely wish to suggest to you very earnestly whether it should not be more carefully considered as to the sending of children here to Colorado, who are strongly predisposed to the development of tuberculosis We do here see a certain number of affected joints and some cases of peritonitis, but in the main children here grow up with a decidedly less predisposition to tuberculosis than elsewhere Where the parents of the children have not developed tuberculosis to such an extent as to compel them to go to Colorado, it seems to me we should consider very carefully whether it would not be wise to send them to Colorado for the sake of the children

Dr **Edwin Rosenthal**, Philadelphia—In the institution with which I am connected, little children picked up on the streets, died in a few days and on postmortem I found nothing at all but tubercular peritonitis Further dissection revealed only an enlarged lobe in the lungs These were little infants that probably perished from exposure and neglect In this home we receive all sorts of children found on doorsteps and so on This brought me to think that the condition of tubercular peritonis is found in infants perhaps more often than we give credit for The so called inflammations of the bowels are often of tubercular character Tubercular peritonitis follows measles as well as whooping cough, and when we have cases of whooping cough or measles that have recovered, we must not discharge the patients too soon, for they are never thoroughly well until months afterwards In fact, we should keep them under observation for at least six months afterward In the case of simple whooping cough, which the Doctor said, if it had any hereditary history, might turn out to be a case of tubercular gland disease, and would end in tubercular disease, if it were a case that had a tuberculosis for an inheritance, it would easily turn into tuberculosis of the knee or hip joint, and the proper etiologic factor would be such diseases as whooping cough or measles

Dr **Louis Fischer**, New York City, in closing —In reference to the remarks of the gentleman who found so many cases among the Russian Jews, I believe that is true because they adhere so closely to the Biblical teachings It seems they have a certain form of inspection which is a sanitary measure They inspect the bronchi and lungs of all animals slaughtered, and if they find nodules and disease, or if they can not inflate the lungs, the animal is rejected Unfortunately, those of us who have strayed from that practice are as prone to that disease as anybody else I purposely went into the matter to find why people with external manifestations of the disease did not develop tuberculosis, and I believe it is simply because the vital factor is not introduced, namely the tubercle bacillus The gentleman stated that where cod liver oil was not tolerated he gave malt I am heartily in favor of giving malt, but the same objection open to cod liver oil is open also to malt, that where the stomach will not tolerate cod liver oil it will not tolerate the action of malt For that reason I have discarded the use of malt When I was associated with Dr Chapin of New York, I noted the weight of children taken before and after inunction Nothing was given but cod liver oil externally, and we were surprised to find how much good could be done in that way Dr Jerowitz of Kansas City mentioned the fact that it is difficult to get the sputum of children in order to make a diagnosis I remember one case at the Post-graduate, in which we were baffled in making a diagnosis The child had a slight elevation of temperature It was one of the cases in which we suspected the possibility of intermittent fever We examined the blood and found no plasmodia On examination of the lungs no evidence of tuberculosis was found, yet examination of a little mucus discharged from the bowel showed the tubercle bacillus The guaiacol treatment is one I use also Fresh air was mentioned and I mentioned the value of sunshine In fact I was very anxious to hear Dr Whitney's views of the value of the climatic treatment, for which my paper was purposely intended The Doctor stated that he found a certain immunity among children in this climate I believe we could secure the same immunity if we had continuous sunshine and fresh air and the value of pulmonary gymnastics I believe where we have little girls from 6 to 10 years old in the East, by making them inspire and expire in the parks, we do more good than by any other means I do not believe the drug treatment of tuberculosis is the real treatment, but sunshine, fresh air, massage, anything plus oil, plus nutrition, are the vital factors in the treatment of tuberculosis

Dr F F **Lawrence** Columbus, Ohio, in closing —I believe

I stated that where we had ascites in the absence of heart, kidney or other visceral lesion which would give rise to ascites, that is presumptive evidence that the peritonitis is tubercular I agree with my friend from Louisville that there are a great many cases not of tubercular character In regard to aspirating, I do not use the aspirator at all about the abdomen I do not like to think that I may plunge the aspirator needle into a loop of intestines and have to make an operation to close the opening Like a great many things (Kentucky whiskey, for instance) it is all right in its place In regard to the remarks of my friend, Dr Tuley, who said, I believe, that I laid too much stress on injury, I said that in cases in which there is a tubercular affection in some other part of the body there may be no injury I still say and believe that it will almost if not quite universally be found that there is some mechanical injury to the abdomen some time before As to when we should commence treatment, the time to begin active treatment in tubercular peritonitis, that is when to operate, is just as soon as we are satisfied that we have a chronic peritonitis, whether tubercular or not We are not justified in taking the chances, of the effusion becoming absorbed and the patient recovering, when an incision and drainage is practically without danger The whole subject of tuberculosis is unsatisfactory so far as its curative treatment is concerned Tubercular peritonitis in children is much more likely to be severe and is likely to follow upon some tubercular condition in some other part of the body

SOME DISEASES COMMON TO THE FEEBLE-MINDED

Presented to the Section on Diseases of Children at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo , June 7-10 1898

BY MARTIN W BARR, M D ,

CHIEF PHYSICIAN PENNSYLVANIA TRAINING SCHOOL FOR FEEBLE MINDED CHILDREN
ELWYN PA

I count not the least valuable to myself of my former collaborations with the late Dr Isaac N Kerlin a study that, we made together—with intent of reducing to tabulated form—of those diseases most common to the feeble-minded This study involved the examination of medical records of 1400 cases, covering a period of twenty-five years, and I have since extended it so as to include some 3000 cases Sifted out, we find the diseases, some eighty in number, distributed equally among the sexes, and in varying proportion in the different grades Broadly considered, there are three conditions or classes which the feeble-minded present to the eye of the medical observer, with modifications of course in different grades, causing the individual, therefore, to repel or to succumb to disease each in a different way We have, first, a physical development according to age, susceptibilities to pain or pleasure being almost normal, and the mental development fair, but limit reached in early youth, what we would call mentally feebly gifted but physically normal, meeting disease much as do normal people under similar environment and with average longevity Second, are those undeveloped in mind and body, as the cretins, for instance, predisposed from birth to certain forms of disease and an easy prey to any

In marked contrast are those who exhibit almost entire habitude to pain, able even to endure amputation without flinching and rather enjoying anything that gratifies the egotistic sense or that brings the individual into notice He is ignorant of pleasurable sensations, absolutely devoid of sympathy with his kind, and being absorbed in self, his thoughts are constantly inverted It is from this class that many of our criminals are drawn For them the gallows has but few terrors and they suffer the extremes of heat or cold, and even the pangs of hunger, without the consequences common to those of ordinary type

Lastly, those physiologically old, who either wear out in childhood of "old age," or else, as old people too feeble to resist sudden attack, die in youth or early childhood Included in this class are those who seem made of such poor material—whose tissues necropsy reveals as absolutely worthless—that they are unable to resist disease or any nerve storm, and simply go to pieces Reviewing these peculiar types the physician ceases to wonder at various apparent anomalies one constantly encounters in our hospital wards Here one falls and passes away from slight cause that would hardly affect a normal babe, another, at the very gate of the grave, with hardly a pulsation or a breath, will suddenly revive and recuperate as a normal person could hardly do

The major nervous diseases, such as Friedreich's ataxia, syringomyelia and hydromyelia, which one would naturally think allied to brain diseases, are practically unknown Anterior poliomyelitis is occasionally found, but the most common nervous diseases are the cerebral palsies of childhood Meningitis is also common and confined almost exclusively to boys of the high and middle grades Hysteria is peculiar to these grades, but occurs most frequently among the girls, as do the various neuralgias True chorea is rare and found not at all among the lower grades, and only in about 5 per cent among the higher, although choreiform movements are fairly common Epilepsy claims about 20 per cent of the feeble-minded, chiefly of the imbecile and idio imbecile class, and is seldom seen in the idiot, either apathetic or excitable

There is much hereditary predisposition to lung troubles which, coupled with lack of resisting power, renders such complications as phthisis and pneumonia inevitably fatal Asthma, bronchitis and pleurisy are not frequent, nor is laryngitis, while tonsillitis, pharyngitis and rheumatism are common among all classes, the latter among the boys of the higher grades Ephemeral fever occurs with the temperature running so alarmingly high that fatal results seem inevitable, and then as suddenly subsides in response to the simplest remedies

Cutaneous affections are rare among the high and middle grade imbeciles, though frequently met with in the low grade and idio imbeciles, due doubtless to inertia and the sluggish and unclean habits that characterize these classes Eczema is common, lingering and persistently returning in spite of most careful treatment Rupia escharotica, tinea, acne, alopecia, impetigo, herpes, erythema nodosum and urticaria are among the list of cutaneous diseases Acne sebaceum or "butterfly disease," of which but twenty cases, including three of my own, are reported, seems to be confined exclusively to the lower grades of mental defectives Ulcers are frequent, especially on the upper and lower extremities, and are obstinate in responding to treatment

The sluggish habits of these children find the usual results in constipation, dysentery, diarrhea, dyspepsia and gastritis Gastric ulcers are found occasionally among the boys, with the girls never Enuresis is common among all grades and is often [illegible] Hemorrhoids are

are common among the higher grades of both sexes, as are also hernia and prolapse of rectum Deficient circulation is almost exclusively confined to imbeciles of the lower grades, thus cyanosed hands and legs and blue lips are characteristics of the idio imbeciles, as also of the grades of the Mongolian type, who often develop scrofula Syphilis is rarer among the feeble-minded than is generally supposed

Defective vision due to errors of refraction is found among 90 per cent of the high and middle grades, and among the low grades there is much conjunctivitis, iritis, corneal ulcer and blepharitis Tests and also class work in the schools reveal a fair possession of color sense, and color blindness is the exception rather than the rule

Absolute deafness is equally uncommon even among the members of the idio-imbecile and idiot class, although partial deafness is occasionally met with Both sexes are subject to otorrhea, and especially to otitis media Hematoma auris is met with in 25 per cent of boys, and is confined almost exclusively to the left ear I know of but one case double Adenoid growths are a fruitful cause of the speech defects found in the high and middle grades, and their early removal greatly facilitates that training in articulation which holds an important place in all schools for defectives

This rapid résumé of a subject of which the limits of this paper will not permit more than a glance may, I trust, be the means of eliciting notes of similar experience from others engaged in work among the mental defectives These collected may in time form a sound basis of theory such as may aid materially in the practical work of the future in our hospitals

---

ARTIFICIAL FEEDING OF INFANTS, ESPECIALLY IN GASTRIC DISTURBANCES

[ABSTRACT]

Presented to the Section on Diseases of Children, at the Forty ninth
Annual Meeting of the American Medical Association
held at Denver Colo July 7-10 1898

BY J M G CARTER, M D , Sc D , Ph D
rofessor of Clinical and Preventive Medicine in the College of Physi
cians and Surgeons Chicago (School of Medicine of the
University of Illinois) Ex president Illinois
State Medical Society Etc
CHICAGO

Gastric disturbances of infants are due mainly to improper food The food may be at fault in quality or quantity Rarely cases of congenital malformation or deficiency are met in which the usual food preparations do not agree If the disturbance is caused by the food and is not due to some deficiency in the baby's stomach, the first inquiry regards the source of the food If the food is mother's milk, the health and temperament as well as the disposition of the mother must be observed If the mother's milk is acid the administration of a little lime water to the baby after each nursing may remove the difficulty Mother's milk may contain too great a relative proportion of proteids and constant functional disturbance in the baby's stomach arise In this and other cases mother s milk may have to be abandoned and some form of artificial food prescribed If the disturbance has continued until organic injury of the stomach has supervened (as chronic gastritis) additional modifications of food may be required The food may require complete or partial predigestion or peptonization Under such circumstances it is often a long and tedious task to find a preparation of food which will entirely remove the condition and relieve the symptoms

Next to mother's milk, cow's milk is the proper food for infants This must be modified so as to correspond to mother's milk Each case requres special investigation If there is constipation and a poorly nourished condition of the patient, cream should be given in larger proportion than in cases of well nourished infants, with a tendency to diarrhea Bearing in mind the fact that normal human milk is alkaline while cow's milk is neutral or acid, a necessity will be recognized for using a little lime water with the cow's milk Sterile milk should be used If proper precautions have been taken in milking the cow and the milk is passed *at once* into sterilized bottles, a healthy cow's milk *is sterile* and needs no heating except to raise it to proper temperature for feeding the baby, about 98 or 100 degrees F The milk must be analyzed, and then by comparing with normal human milk a formula can be given and the milk prepared as needed

Human milk contains water 88 4 per cent , fat 4 per cent , lactose 6 5 per cent , proteids 1 8 per cent If a cow's milk is found to contain water 87 3, fat 4, lactose 5 69, proteid 2 80, a simple calculation shows that to reduce the cow's milk to the equivalent of mother's milk it is necessary to add 57 1 per cent of water To prepare 500 c c of this modified cow's milk from the specimen here given will require 312 c c of milk and 178 c c of water (174 water and 4 lime water) To this must be added 9 c c of cream and 10 gm of lactose

When it is not convenient to analyze the milk, a good average food may be thus prepared Skimmed milk 300 c c , water 166 c c , cream 30 c c , lactose 8 gm , lime water 4 c c If constipation occurs, increase the proportion of cream, if diarrhea, reduce the amount of cream or increase the proportion of lime water Sometimes colic and even diarrhea may be caused by the proteids in cow's milk and it is found necessary to reduce the quantity of milk and increase the proportion of cream

It occasionally occurs that summer heat, or some condition of the stomach, may cause such digestive disturbance that cow's milk must be totally discarded When such is the case, evaporated milk, malted milk, malted meat, milk food, and similar commercial preparations may be tried, selecting with a view to the conditions prevailing in individual cases

SOME PERSONAL EXPERIENCES IN INFANT FEEDING

Presented to the Section on Diseases of Children at the Forty ninth
Annual Meeting of the American Medical Association
held at Denver Colo June 7-10 1898

BY WILLIAM H WELLS M D
Adjunct Professor of Obstetrics and Diseases of Infancy in the Philadel
delphia Polyclinic Instructor of Obstetrics in the Jefferson
College Fellow of the College of Physicians of
Philadelphia Member of Pediatric
Society of Philadelphia
PHILADELPHIA PA

There is no question in pediatric medicine which at the present time is exciting more interest, and justly, too, than the subject of artificial feeding of infants Where the mother has well developed breasts, containing a plentiful supply of good milk the question of infant feeding is an easy one, and it is not the object of this paper to discuss the question of breast feeding, or even to touch upon the manner by which, as far as our knowledge at present reaches, the lacteal secretion in the breast can be modified by food and general hygiene It is our intention to dwell in a brief manner only on the subject of the feeding of infants by artificial means, first, by foods derived from the milk of the cow or other animal, second, by foods made more or less directly from the grains In the study of this question we have made our observations chiefly in the infant's clinic of the Polyclinic Hospital of Philadelphia, as district physician among the poor in one of the most populous parts of that city, and also among our private patients

The indications for the withdrawal of breast milk and the adoption of artificial feeding are that whenever the mother or child is suffering from a continuance of breast feeding, the child should be weaned As special indications we would mention syphilis, either in the mother or child, tuberculosis or other wasting disease, and any of the exanthemata in the mother Pregnancy and menstruation frequently so alter the composition of the milk as to require weaning Hard work, poor food, and general bad hygienic surroundings may render the mother's milk unwholesome for the child Whenever the milk is below par in quality, this being evidenced by less than the normal gain in weight from week to week on the part of child, or where the breast milk for some unaccountable reason disagrees with the child and can not, after a reasonable attempt, be so modified as to suit the digestive organs of the infant, the latter should be weaned Women with uncontrollable nervous systems make, as a rule, poor nursing mothers, so that this alone may be a cause for the substitution of artificial feeding Occasionally we find infants whose digestive systems are too weak to assimilate their mother's milk, these children generally thrive better on modified cow's milk than from the milk in their mother's breast With our increased and more accurate knowledge of infant feeding, especially by the use of modified milk, the scope of what is generally known as artificial feeding is so widened that we often find an infant will thrive much better when fed by this means than from breast milk In discussing the subject of infant feeding we will briefly consider 1, feeding by the modified milk of animals, particularly the cow, *a*, cow's milk modified at home, *b*, cow's milk modified in laboratories, 2, Gaertner's so called fatty or mother's milk, 3, condensed milk, 4, proprietary foods

Modified milk —The milks of many animals, notwithstanding quite marked differences in the proportion of their chemical constituents, may be so modified as to closely resemble the milk of the human female It must, however, at the same time be borne in mind that the digestibility of the mixture does not entirely depend upon the fact that the proportion of the various elements (fat, sugar and proteid) may be so arranged as to closely resemble human milk, but the character of these elements must be as near as possible to the latter Thus, as everyone knows, the proteid of cow's milk is far less finely divided and is tougher and less flocculent, when precipitated by hydrochloric acid or rennet, than is the proteid of the milk of the goat or of the human female The proteids of different breeds of cows also vary thus the Devons, Durhams, Ayrshires and Holsteins, give milks the proteids of which are more finely divided, not only as regards their division in the emulsion of the milk, but also in the precipitated proteids, than the same elements in many other breeds of cattle notably the Jerseys The fat of milk must also be in nearly as fine a degree of subdivision as is found in human milk, and in this the milk of animals differs much, even among various breeds of cows there is found a wide difference, the Holsteins, for instance, giving a much finer emulsioned milk than probably any other breed As a rule a breed of cow noted for giving the best milk for buttermaking is not the best for infant feeding, because the milk which makes the best butter is one with large fat globules, i e , a coarse emulsioned milk, while as we before stated, a milk for infant feeding must be in a state of fine subdivision, in other words a fine emulsioned milk, As in by far the largest number of cases we are compelled to depend upon the cow to act as a foster mother for the human infant, we will only take the time to merely *touch* upon the question of the milks of other animals

Goat's milk is often of great service in infant feeding, the animal is easily obtained, is not expensive and is not hard to keep Its milk is well taken and assimilated by infants It is also capable of considerable modification An analysis of goat's milk which the author had made shows the following proportions of its constituents

Goat's milk —Fat 5 85, proteids 1 49, sugar (lactose) 5 11, mineral matter 0 88, water 83 67

This is to be compared with the relative proportions of fat, proteids and sugar in cow's and human milk

Cow's milk –The Walker Gordon Laboratory Analysis —Fat 4, proteids 1, lactose 4 50

Or human milk, same analysis Fat 3, proteids 1, lactose 6

It has been the author's experience, however, that in goat's milk the toughness of the proteid elements and their divisibility, vary more with the diet of the animal than do the proteids in cow's milk Ass s milk is said to prove satisfactory, but we have had no experience whatever with it Various preparations of milk, such as Koumys, Kephir, etc ,we have used but seldom These undoubtedly have some use for the nourishment of infants with feeble digestion, but their long continuance can not be recommended In view of these facts we return to the consideration of cow's milk

The composition of cow s milk differs considerably from that of the human female In the former the proportion of proteids is considerably higher than in human milk, and the character of the casein is tougher The proportion of fat is nearly the same in both possibly somewhat larger in cow's than in human milk There is, however, such an enormous difference in the analyses of cow's milk made by various observers that it is extremely difficult to get a standard test upon which to base our calculations The proportion of sugar is decidedly higher in human than in the cow's milk and the degree of alkalinity is slightly greater in the milk of the human female The object in modifying cow's milk is to bring the proportions of the various elements as nearly as possible to those of human milk Thus we add water in order to dilute and thereby decrease the considerable excess of proteids, but as in so doing this the sugar and fat are reduced below the proportions found in human milk, we must add these elements in the form of cream and sugar of milk or cane sugar This is the fundamental principle for modifying milk Milk in some form is undoubtedly the food for infants, as during the early months of life the starch digesting functions of the digestive organs, while perhaps not absolutely undeveloped, are incapable of continued action Allowing then that milk is the best food for infants, and that cow's milk can be so universally obtained, we consider that modified milk is the simplest and cheapest food that can be used, and in our experience its results are far superior to any patented infant food It is also capable of an almost endless variety of changes in the proportions of its principal constituents, and on this account it can be adapted to the digestive organs of almost every infant, if only a little care in the study of the case is exercised The next question is, how milk should be modified The proportions of the various elements must be arranged to suit the digestion of the individual child that we are treating, and frequently many changes must be made in the modifications before the desired result is obtained We have arrived at the desired point when a child previously illy nourished gains as does the average breast fed baby, of the same age and in good health As a pioneer in this branch of medicine the profession owes a large debt to Professor Rotch of Boston, and it is upon his most carefully computed tables that most of the scientific knowledge of the use of modified milk for infant feeding is at present based throughout the world

Home Modification—In treating the subject of home modification the author intends giving more of his own clinical experience than to the consideration of the subject as found in accurately compounded tables based on calculations involving a deep knowledge of high mathematics We have not infrequently seen these demonstrated at society meetings, and in journal articles as being "short and easy methods of calculating the proportion of the various elements of milk" In many cases these short methods occupy one or two blackboards, or two or three pages of a journal article in the working out The knowledge of the average mother does not extend this far, neither has the general practitioner time to spend all of one set of office hours in working out these problems However, a thorough knowledge of the method of computing these formulæ should be well understood by all those who are special students of pediatric medicine In our own experience it seems to be most important to get some formula as a basis, and to vary the proportion of the elements therein until a modification is obtained, which will suit the digestion of the particular case we are treating We can make few general rules in infant feeding, each patient must be studied from its own standpoint In our hospital work we are in the habit of taking as a basis a prescription such as the following, this being one of Rotch's formulæ Proteids, 1 00, fat, 2 50, sugar, 6 00, lime water, 5 00

This can be made as follows allowing that the cream furnished the average household does not contain over 10 per cent fat, and this generally happens Cream, 5 oz, milk, none, lime water 1 oz, water, 14 oz, milk sugar, 8½ teaspoonfuls In this formula we purposely kept the proportion of fat and proteids rather low, to allow for the greater toughness of the cow proteids This milk mixture we are in the habit of giving Pasteurized, that is, heated to about 170 degrees F The quantity for a child of three to five months is usually from four to six ounces, and the interval of feeding every three hours during the day (from 5 A M to 10 P M) and once during the night It is of the utmost importance that a baby be fed at regular intervals, and if the child is asleep when the feeding time comes it should be awakened If the above formula agrees it should be continued as long as a suitable gain in weight occurs, and the digestion remains in good condition As a rule we are in the habit of increasing the proteid and fat and decreasing the sugar as the child grows older Should any symptoms of indigestion arise the proportions must be changed A little study of the subject will quickly tell us which one of the elements is at fault It is only necessary to call your attention to the fact that where the proportion of proteids, for example, is too high the child will have colic, irregular attacks of diarrhea and constipation, the vomiting of curds and curds in the stools, or where the proportion of sugar is too high there will generally be frothy stools, acid in reaction, frequently producing considerable irritation of the parts around the anus, etc

For home modification among our out-patient infants in the Polyclinic Hospital we generally use the following method As soon as we have determined to wean the child, and have satisfied ourselves that the digestive organs are in a healthy condition, we place the patient on some such formula as the one before given, the prescription being filled in on a printed form, such as the following

Feeding—Milk mixture of ounces Fresh milk teaspoonfuls or ounces Boiled water teaspoonfuls or ounces Fresh cream teaspoonfuls or ounces Sugar of milk teaspoonfuls or ounces Peptogenic milk powder measures Lime water

After mixing the above in a nursing bottle, place the bottle in boiling water for ten minutes, but do not allow the mixture to boil Let it cool sufficiently before giving it to the baby Feed the baby every hours and once during the night

Keep the baby in the arms while feeding and hold the bottle for it

Do not allow it to lie down and nurse itself

Have two bottles and two nipples, and alternate in using them

If the child does not take all of the milk *throw the balance away* Do not keep it

After using it scald the bottle and nipple with boiling water, then fill the bottle with water containing some bread soda or borax

Put the nipples in a cup or glass and cover them with some soda or borax water Keep them there when not in use

Before using again rinse both the bottle and nipple with boiling water Never use tubes

Drink—A baby needs water Give it from one to four teaspoonfuls several times a day Boil a bottle full in the morning, and cork it up and keep it in the refrigerator for use during the day Use only water that has been boiled

Bathing—Wash the baby once or twice every day in warm water with castile soap Sometimes a little rock salt added will be good

Clothing—Have the bandages of wool, and not too tight Tight bands keep the baby from breathing freely The rest of the clothes should be cool Have clean clothes every day if possible

Change the diapers as soon as soiled, and wash the parts while doing so Never use a diaper that has not been washed thoroughly in boiling water

Fresh air—Take the baby out in the morning and evening in hot weather, and keep in a cool place during the day

Note—*Follow the doctor's directions implicitly*, and never give the baby any medicines that have not been prescribed by him

If for any cause we have reason to change the formula, we pick out from our milk tables one which is adapted to the needs of a child in the condition of the patient Each formula of our tables has on one side the percentages of fats, proteids and sugar with the degree of alkalinity, and on the other side the amounts of cream, milk and sugar in drams and ounces These latter we change to teaspoonful and tablespoonful, so as to be more easily read by mother or nurse We always have the patient return at least every other day and its symptoms are carefully noted Should any element of the milk formula seem to be disagreeing, this is changed to suit the indications of the case, and should the mother or nurse not understand the methods for the preparation of the milk, we always send one of our clinical assistants to show her By this very simple method we have saved the lives of some hundreds of infants, and we are happy to say that we have very seldom found even the most ignorant mothers who could not follow these simple rules Sometimes when we are in doubt as to the mother's preparation of the milk mixture we have the mother bring a bottle to us for testing In a future edition of these slips we intend having the rules printed in several languages, as our clinical patients are of all nationalities Among private patients it is often possible to go a step farther, and to use the methods for the home modification of milk which are described by Rotch and revised by Cautley The articles required are as follows A wide-mouthed glass jar holding one quart, a syphon of glass tubing, one quarter to one-half an inch in diameter and bent so that the end out of which the milk is to flow is six inches longer than that inserted into the jar One quart of fresh milk from a herd of cows is thoroughly strained and put into the jar, which is kept open for fifteen minutes in order to allow it to cool The jar is then sealed tightly and placed in a vessel containing ice-water and salt in the proportion of a teaspoonful of salt to a quart of water This is set in a cool place for six hours At the end of this time syphon out from the bottom of the jar three-fourths of the milk into a clean vessel The mouth must not be used to start the flow of milk through the syphon, but the latter must be filled with clean boiled water, the lower end closed with the finger and the syphon inverted, the shorter end being placed in the milk When the finger is withdrawn the water, followed by the milk, will run out of the longer division The materials necessary for preparing the milk mixture are as follows First, the milk which has been syphoned from the jar, second, the milk which remains in the jar and which contains 10 per cent of fat, third, milk sugar This may be purchased by the pound and divided by the druggist into packages, each containing 3⅜ drams or 200 grains Fourth, some lime water, fifth, some well boiled and filtered drinking water The milk sugar is first to be dissolved in the water and the other ingredients added in the necessary proportions

Holt's most excellent formula, as given in his textbook, while simple and practical to those who have had considerable experience in the use of modified milk, we have found too complicated for home use We must repeat that we consider the most important point in favor of the use of modified milk is the ease with which the proportions of a certain formula may be changed to suit the peculiarities in the digestion of the individual child we are treating It is not always necessary to adhere to intricate calculations if we have only one basic formula to work on A study of the symptoms produced by an excess or scarcity of any one element will speedily enable us to tell whether the milk is agreeing or not

MILK LABORATORIES

Of late years reliable milk laboratories have been established in different parts of the country In 1891 Mr G E Gordon established in Boston what was known as the Walker Gordon Milk Laboratory Since then branches of this house have been opened in New York, Philadelphia, Baltimore, Montreal and Chicago These laboratories furnish milk, which is modified upon a physician's prescription, in exactly the same manner as an apothecary dispenses drugs Briefly, the principal points of superiority of this method are as follows 1 The primal milk supply is under the supervision of the laboratories and the cows are selected, cared for and fed with but a single purpose in view, namely, the production of a milk suitable for infants' use 2 The freshness of the milk is not impaired by the process of preparation In these laboratories the milk is modified exactly and scientifically Every infant has milk freshly prepared, the formula being made to suit the particular digestion, the fats, sugars and proteids being prescribed with this object in view 3 The milk is modified and sold upon the physician's prescription, so that over-anxious mothers and nurses can make no mistakes as to the quantity and quality of the milk preparation The greatest advantages in this method are the accuracy of the prepared food and its careful sterilization or Pasteurization before its delivery The principal disadvantages are that it is somewhat expensive, and at the present time such milk is hard to obtain within more than one hundred miles of any of our cities In compounding and modifying milk, the directors of the laboratory consider the milk only in the light of its component parts In the modification the following articles are used 1 Cream which contains 16 per cent of fat (centrifugal cream) 2 Separator milk from which the fat has been removed by a centrifugal machine 3 A standard solution of sugar of a strength of 20 per cent It is possible by varying these elements in different proportions to produce almost any degree of modification In writing a prescription for a modified milk, the physician fills out a regular prescription form furnished by the laboratory, using any percentage of fat, sugar or proteids that may be desired, giving the quantity desired for each feeding and the number of feedings in the twenty-four hours The laboratory furnishes a daily supply in the bottles from which the child is to be fed

Among the most recent methods of modification is that of Dufour (*Rev mens des Mal de l'Enfance* September, 1896, quoted from the American Yearbook of Medicine and Surgery)

Dufour gives the following method for humanizing cow's milk Put the quantity suitable for one day at the child's age into a large graduate with a corked spout at the bottom Set aside tightly covered and and at a proper temperature for four hours to allow the cream to rise Draw off one-third the lower milk and add the same amount of water Add 35 grams milk-sugar and 1 gram of salt per liter Shake and pour into sterilized bottles If the child's gain in weight is unsatisfactory, add a teaspoonful or two of cream to the whole amount of milk (The replacement of one third of the bulk of milk by an equal quantity of water reduces the proteids and salts of the milk, but does not reach the proteids of the cream) More definite results are obtained in the wholesale manipulation advised by Dufour, in which the milk is diluted with one third of water and to each liter of the mixture are added 15 to 20 grams of milk-sugar and 1 gram sodium chlorid. The amount of cream here added produced 4 per cent. or more of fat. This preparation is used in all cases, the amount at a feeding alone varying with the age of the child.

Hesse describes in detail in the *Berlin Klin. Woch.*, July 27, 1896 (quoted from Yearbook of Medicine and Surgery, 1897), an improvement on the so called Dresden modification, a description of which, from an English observer, Worcester, was given in the Yearbook for 1897. Using Lehmann's analyses of human milk and cow's milk, Hesse demonstrates that if to 1 liter of 9.5 per cent. cream, 1½ liters of water are added, and to this 105 gm. of milk-sugar and fresh egg albumin (enough to represent 9.5 gm. dried albumin) a mixture is produced yielding 1.2 per cent. casein, 0.5 per cent. albumin, 3.8 per cent. fat, 6 per cent. sugar and 0.4 per cent. ash. To insure sterilization, however, he found that better results could be obtained by drying and pulverizing the paste of albumin and sugar, and the similarity to human milk was more closely approached by adding to this in process of manufacture a certain amount of lacto saccharate of iron. The resulting sterile powder is readily soluble in water, and when added to the diluted cream produced a mixture very closely resembling mother's milk in all its ingredients. In practice it was found that a reduction of the fat percentage to 3, and of the sugar percentage to 4.5 gave a more readily digested mixture. In a series of cases fed from birth to 1 to 5 months the average monthly gain was 13 oz. (not a very encouraging showing under conditions most satisfactory for testing a new process of feeding).

Gaertner's fatty or mother's milk.—Gaertner, in his *fettmilch*, or mother's milk, aims to reduce the excess of casein in cow's milk by the use of the following method. A separator, known as the Pfanhauser centrifuge, making 4800 revolutions a minute, is employed. The machine is filled with equal parts of fresh cow's milk and sterilized water. The speed of the centrifuge is regulated so as to separate the mixture into 1, creamy fatty milk; 2, skimmed milk. The two portions are led off by as many openings. An analysis of each of these portions shows that the creamy milk contains the same quantity of fat as found in human milk. About 2 per cent. of the casein is contained in the skim milk, and the balance, 1.7 per cent., remains in the creamy milk. In order to bring up the proportion of sugar to that found in human milk about three or four gms. of milk-sugar are added to every 100 c.c. of the fat milk. It is claimed that the fat milk has the advantage over diluted milk of having a higher percentage of fat, while the curd is rendered more digestible. This method of infant feeding has been quite extensively tried by Dr. Louis Fischer of New York, who claims to have had excellent results. Our own experience with it has been somewhat limited, and while the results have been fair, we do not think that they have been equal to those obtained from the use of modified milk. We are, however, still using it, and hope to be able to make a further report at some future time.

Condensed milk.—Condensed milk is largely used by the poorer classes as an article of food for infants. Being sealed in air-tight cans or jars and containing a large quantity of sugar it is easily preserved for a considerable time. It is also cheap and prepared with comparatively little trouble—both qualities which recommend it to the poor mother with the care of a large family. All that is necessary for its preparation is to mix with a certain quantity of water and pour into a nursing bottle. The proportion of lactose and cane sugar in condensed milk is in excess of that found in the human or cow's milk, yet the amount of fat and proteid, as well as the alkalin mineral matters, is considerably less. It is true that the large amount of sugar present tends to prevent constipation, but the other elements being disproportionately small makes condensed milk, as an article of food, deficient in general nutritive properties.

Children fed on condensed milk soon become fat, and for some time the digestion really seems to be improved; this is more frequently the case if the child is changed to a diet of this substance from one of farinaceous foods. After a continued diet of condensed milk, however, a child generally becomes flabby, restless or sleepy, suffers from impaired digestion with considerable fermentation, and is apt sooner or later, to drift into a condition of marasmus. Some of the worst cases of simple atrophy that we have seen have been infants who have been fed for a long time on this form of diet. In these children the period of dentition comes later, is irregular and prolonged, and a strong tendency to rickets or a chronic state of malnutrition is manifest. It has also been noticed that if children fed on this diet fall into a subacute diarrhea, it is almost impossible to save their lives.

Proprietary foods.—Many of these foods seem to be quite carefully prepared, and, having the advantage of convenience and cheapness, may be introduced with good results by the end of the first year. It has been taught by some authorities that finely-divided starch or dextrin introduced into milk acts in two different way. First, by its nutrient powers and secondly by its mechanical action. By mechanical action was meant that it was supposed the particles of the starch or dextrin so diffused themselves among the globules of fat and casein of the milk that the former were prevented from separating from the emulsion and the latter could not form a tough curd in the digestive tract of the child. This theory has of late years been disputed, and experiments seem to prove that the action of these substances as attenuants, so-called, is of little consequence. As far as their nutritious properties are concerned, the starchy or dextrined foods are far inferior to milk, for two reasons. First, the proportion of tissue building to the heat-producing elements is much below that of milk. In the second place, the starch, which is a heat-producing principle, must be converted into sugar before it can be absorbed. This change is accomplished by the action of the pancreatic juice and saliva, neither of which are to any extent established before the fourth month of life. The undigested starch, therefore, remains in the gastro intestinal canal and is extremely likely to cause fermentation. In order to make up in some degree for lack of nutritive properties, all farinaceous foods should be prepared with milk, and it really becomes a question whether in infants under 8 or 10 months of age, the nutritious principles are not dependent much more on the milk than on the food itself. In regard to proprietary foods it may be said that their best quality is that they form an easy and convenient way of introducing starch or partially dextrined starch into some modification of milk.

Dextrined foods.—Many preparations are sold in which, by previous heating or by digestion with diastase, wheat or barley flour is so modified as to be more easily digested than simple starch By the action of a temperature of 300 or 400 degrees F the principal substance, starch, forms dextrin a body differing from starch in the fact that it is soluble, and has the characteristics of a gum Quoting from the investigations of Professor Leeds, we find that the flour selected for such treatment should be rich in albuminous substances and made from wheat grown at certain seasons and of a certain grade, and should be made by the roller process

Liebig's foods —Under this head may be classed a number of proprietary foods, the essential construction of which is as follows The flour is prepared by means of diastase, equal parts of wheat flour and barley being used, and a certain amount of wheat bran added The latter substance is used because of the adherent phosphates and nitrogenous matter To these 1 per cent of bicarbonate of potassium is added, with water sufficient to make a thin paste This mixture is allowed to stand for several hours at the ordinary temperature, after which the latter is raised to 150 degrees F , and this is continued until all the starch is converted into maltose and dextrin The mixture is then strained and the residue pressed and exhausted with warm water, after which the extract is evaporated into vacuum jars at a moderate degree of heat The process is completed by drying at a higher temperature, the mixture being stirred thoroughly

Dextrined foods intended to be used without milk —This class of proprietary foods are prepared with the intention of using without the addition of milk, water only being necessary to prepare them for the feeding In the majority of these the starch, which has been partially or completely converted into dextrin, has been evaporated with milk during their manufacture An outline of their preparation is somewhat as follows The flour is first made into dough and baked, after which it is finely ground and mixed with condensed milk and then dried by a slow heat of moderate degree In the resulting mixture the starch has been wholly or partially converted into maltose or dextrose The albuminoids of the flour have undergone about the same changes as take place in other farinaceous foods The milk-sugar has undergone coagulation and the casein has become dried into a fine powder An example of this class of foods is the one sold under the name of Nestlé's Food Somewhat recently a food known as Eskay's Albuminized Food has been introduced The manufacturers of this food have endeavored to combine egg albumin with the other constituents

In regard to the value of these foods, we must say that there is no one of them that can be referred to as being the best upon which to feed a large number of children or a single child during a long period of time That they have a certain amount of usefulness can not be doubted, but our experience has taught us that for a diet for children under 10 months of age they are far inferior to modified milk

333 Pine Street

Glycerin in Chronic Rhinitis —Molteni considers this treatment the most effective for this affection The glycerin is best applied introduced into a pig gut or fish bladder previously inserted in the nose, through which it exerts its effect on the congested vessels *Gazetta degli Osp e delle Clin* , September 8

PROMPT ATTENTION TO EARACHES IN INFANCY AND EARLY CHILDHOOD

Presented to the Section on Diseases of Children at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10 1898

BY LOUIS J LAUTENBACH, M D

PHILADELPHIA PA

Children are not only more sensitive to abnormal impressions from without, but are more responsive to curative influences within, whether natural or artificial As a general rule, it may be considered that they are more quickly affected by disease and influenced by treatment, inversely as their age In adults the power of resistance is great, but when the limit of normal poise is once overcome, disease lasts a comparatively long time and convalescence is slow, whereas in children, we know how suddenly an illness reaches the danger point, and after a comparatively short run, is better This rapid recuperative power of the child is not always an unmitigated blessing, as it is often presumed upon, and from too great a reliance on nature, diseased conditions are overlooked, and the convalescent disposition is undermined and sometimes physical structures taxed beyond power of restoration

The result of this sort of unintentional neglect is seen nowhere more clearly than in the consideration of ear pain in infants and children Pains in the ear are often such a common story in a household where there are several children, that little or no remedial attention is paid to them, and this lack of attention is by no means confined to the poor and ill-informed, but is observed frequently among the educated and well-to-do

We are constantly informed as to a child's having had or having earache for days or weeks, sometimes that it is subject to recurring attacks, and yet the parents have done nothing to relieve the pain or inflammation, relying on the apparent results of preceding attacks, that the child has not become markedly worse therefrom They do not even ask ordinary advice, asserting sometimes in a half-questioning manner, that the attack of pain will gradually disappear, or will mention some family tradition to the effect, that children outgrow them Some, indeed, carefully shield the child from cold, or employ laxatives and confine it to a mild diet Again, some will have used hot sweet oil or glycerin, or laudanum with glycerin or sweet oil, to relieve the pain, but only a small proportion will have used any rational measures to allay the pain, and those who, in addition, have used measures to overcome the cause, are very few indeed

Unfortunately, this complacent view is sometimes shared by the family physician Too often he advises no treatment Sometimes the treatment instituted is irrational and not directed to a *prompt* dissolution of the trouble That they do require immediate attention is evident when we observe the after history of these cases of neglected ear pains

It is a *matter* of common knowledge that more than three quarters of all cases of ear affections originate in diseases of the throat and nose, and extend to the ear Those arising from primary inflammation of the ear structures are rare There are a few cases arising from toxic or specific blood conditions, as well as a very limited number due to some primary influence on the nervous structures

Whenever ear pain is present exploration of the nose and throat should invariably be made If the condition of these parts were not known before, the examination may shed considerable light on the special structures examined, as well as on the condition of the general health We will almost always find some throat disease present, either obstructive or inflammatory in character Enlarged and inflamed tonsils are the most common, but pharyngitis, edema, ulcerations, abscesses, elongated uvulæ, as well as nasal catarrh, polyps and pharyngeal adenoids are by no means uncommon To the light shed on the pain from these sources, we must add that obtained from an examination of the general condition of the child's circulatory, nervous and muscular systems

It is not uncommon to find the throat and ear condition secondary to malnutrition from indigestion and even comparatively mild forms of acid dyspepsia In fact, many of the supposedly rheumatic cases of throat, nose and ear diseases in children, attended by soft hypertrophic nasal swellings, with profuse discharges, or by soft spongy tonsillar enlargements with attacks of ear pains occurring usually two or three times a year, are undoubtedly, in their origin, cases of acid fermentation, and by strict attention to diet in their onset, would often be avoidable

This question of diet is a most important one, and by strict attention to measures based on a recognition of its importance, physicians have of late years been able to prevent much suffering and to save thousands of lives, but what is a greater gain to the race, are enabling men and women to become healthier physically and therefore mentally, than any that have gone before Children's habits especially, vary so much that each child must be carefully studied so as to observe to what extent his ways invite colds or nervous exhaustion with the development of reflex and inflammatory conditions

Many times, the attacks are caused by a general or local chilling of the surface of the body from improper or insufficient clothing, or from moistened clothing about the buttocks or chest All skin clothing, that is the first layer from the neck to the toe, from January to December inclusive, should invariably be of wool It absorbs more water from the skin than any texture of equal weight and retains within its fibers more air and greatly lessens the liability to chills and colds This hygienic law applies equally to adults Some mothers, believing in the hardening process, or because of fashion, dress children with insufficient clothing—legs and arms bare, neck and upper chest exposed Among the poor, such exposure occurs often from necessity

Again, harm is done by the prevalent doctrine that the night, clothing should not be as heavy or warm as during the day This view is certainly absurd At night, the coverings should be usually a little more and warmer than in the day, because, during the day, while the body is in motion, it adds, by combustion, more heat than when the body is quiet To keep the same temperature of the body at night, would require the covering of the body with a greater amount of heat non-conductors It is a fact that the night-sleeping body, not usually exhaling as much moisture as the day-working body, requires less heat to protect it from chilling, yet during the day, the extra heat needed, is supplied by the combustion of muscular tissue elements, whereas this is entirely withdrawn while asleep The clothing during sleep, should be a skin covering of wool with as much covering beside, as will equal or exceed that worn during the day

Some neglected earaches may get well without treatment, but as a rule, the child's physical condition, as well as his ear, is to some extent affected by every inflammation of this organ Continuous pains of the boring, pressing, bulging kind exert an influence on the nervous system, which is often somewhat relieved by violent sobbing, restlessness and great irritability, but the nervous system is weakened, loses its energy, and is sapped at times to such an extent as to produce convulsions and even cause death from reflex phenomena

Inflammation of the middle ear cavity, which is almost without exception present whenever there is ear pain, if unrelieved by nature or art, extends and gradually involves the surrounding parts and later on affects the bony structures, giving us mastoid disease with sometimes a mastoid opening, or, again, extending through the tympanic plate, causing meningitis and at times cerebritis Sometimes it involves the sinuses, causing phlebites, resulting often in death In children pus formation is so much more common and rapid than in adults, that we usually have pus formed early and quickly, infiltrating the surrounding tissues Rarely do we have mucus or epithelial excretions It is because of this peculiarity of rapid pus formation that sometimes serious results occur in these cases, before any provision has been made anticipating the involvement of the fatal spot

I recall having been sent for some years ago, to see a case of ear disease, occurring in a child four years of age In his letter to me, the doctor, after describing the onset of the symptoms and the progress of the case, mentioned that though he preferred me to see the case the day the message was received, if I found it inconvenient, the next day would do, mentioning that he scarcely deemed it essential that the case should be seen by a specialist, yet, to satisfy the family, he thought it best to do so This message was received shortly before noon, and as I was preparing to go to see the child about 4 o'clock the same day, a messenger came from the family, announcing that the child had died of the ear trouble It appears that it had been a case of earache occurring in a child rather subject thereto, and in which few if any measures had been taken in the past to arrest or cure the trouble This attack proving more severe than usual, they called upon their family physician some two or three days after the onset He, believing the case needed a little tonic and sedative treatment, prescribed accordingly On being sent for again the same day, he advised the use of warm oil and laudanum The next morning, the child having suffered violently with pain and having been unable to sleep, he was again sent for and used several doses of morphia, and ordered the bowels to be freely opened with mild chlorid of mercury Upon returning to his office, he sent me the note above referred to The child died the same day in a state of collapse, the severe pain persisting, until unconsciousness appeared No postmortem examination was made, but it was undoubtedly a case of cerebral involvement, following upon the erosion of the tympanic plate These cases are numerous, far more so than is usually supposed Undoubtedly many a case which is thought to be a specific variety of meningitis, is but a concealed case of ear disease Many a case of supposed stomach and internal disorder with malnutrition, has died from ear disease I, personally know of three such cases, and have heard rumors and have indefinite knowledge of others

Some of the children supposed to have died as the result of a blow or a fall, would never have died therefrom, had there not been present concealed ear diseases, affecting the mastoid or other parts of the temporal bone In two such cases I have been compelled to testify before the coroner, to exonerate from the charge of murder, those who had inflicted such blows In both cases, the mastoid was riddled and honeycombed with old disease, and in both was the cerebral surface of the temporal bone eroded, making direct connection between the brain cavity and the tympanum In one, there was, in addition, a cerebral abscess directly connected with the diseased ear

The symptoms in another case, interesting in this connection, were those of a young lady, who was sent to me from the upper end of Bucks County, and who died in our city while her case was being studied by several of our physicians She was sent to me on account of her sight, there being entire loss thereof The condition was that of total atrophy of the optic nerve, but there was in addition, the history of epileptiform attacks From the history of the case and the physical examination, there seemed to be sufficient evidence of increased cerebral pressure, supposed to be occasioned by a brain tumor, to justify the consideration of an operation After several weeks of hospital observance, by one of our most distinguished surgeons, he declined to perform it, believing it not to be justified Her general health was very good She was in the best physical and mental condition, when one night she retired early, as usual, and was found in a normal sleeping attitude, dead in the morning The postmortem revealed a large cerebral abscess, directly connected with a perforated internal plate in the temporal region, the temporal bone, being in great part destroyed During her life, her hearing had not been markedly deficient in either ear and her drum heads were intact but thickened After death, it was learned that as a child she had had violent, frequent attacks of ear pain with frequent pus discharges, but for some six years before her death there was no history of ear disease or ear pains of any kind

The symptoms in the two preceeding cases had been—as in the last case—attacks of pain lasting for days, at times mild and again almost beyond endurance, exaggerated at night, sometimes attended with and sometimes without pus discharges, yet the family in not one of these cases, seems to have realized the danger of these symptoms or the importance of prompt treatment

Of late years, accurate examination of the bony ear structures has been far more common at postmortem than formerly, and the frequency with which extensive disease in this location had been found, has much surprised the pathologist and the coroner, the decision in numerous cases being that death has been caused by ear disease where the diagnosis made during life had been far otherwise Very many cases of deaths from unrecognized ear disease, especially in children, have occurred in the past, and even now occur yearly by the score in all of our large cities and throughout the country

The story of ear pains, and therefore of ear inflammation, is one which should be displayed prominently in every nursery and school Ear pains are dangerous; they are not fleeting, evanescent nothings but indicate a condition of inflammation of the middle ear, which is necessarily followed by more or less damage to the parts and impairment of the general health

Among the minor points to be considered are the tendency to recurrence and the consequent nervous and physical exhaustion engendered and the impairment of hearing more or less great and more or less permanent, the necessity of throat and nose examination and treatment, and attention to the general condition and mode of life

Among the more serious aspects to be considered are 1, the possibility of the attacks causing total or considerable loss of hearing, and the consequent lack of proper mental development, 2, the serious inflammatory complications terminating in idiocy or epileptiform convulsions, 3, weakening of the bony structures about the ear, predisposing to their serious involvement from slight accidents and to attacks of cerebral disease

The citing of perhaps a few aphorisms in regard to their avoidance and cure is more important than a recounting of their danger Whenever a severe catarrh of the nose in a child occurs, call in the physician If the attack be a mild one, use protectors, preferably of petroleum ointments, within and about the nose If the throat is diseased, have it treated If the nostrils are obstructed they should be cleared If the tonsils are enlarged, they should be reduced or removed Any general derangements present should be recognized and attended to at once

All cases of ear pain should be referred to a physician, and pending his arrival, sweet oil can be rubbed into the neck and about the ear, or tincture of iodin be painted over the mastoid, or if the pain is severe, even a cantharides plaster can be applied If the pain continues or is excruciating, syringe the ear gently with hot water or apply a hot water bag or hot wet cloths or even hot flaxseed poultices frequently renewed, keeping head high above level of rest of body Occasionally, ice gives the most relief If severe pain persists, use hot bags at feet or a hot footbath followed by dry heat, sometimes a mustard poultice on the stomach, is required in addition Use cathartics, especially calomel, liberally and keep the child on a mild diet Examine the ear carefully, whenever ear pain is present, and determine at once the nature of the trouble and act in accordance with the conclusions reached

If the ear pains and the subsequent progress of the disease present in cases of acute fevers, were but promptly and properly attended to, there would soon be a marked decrease in the number of the deaf in our midst The neglect of these cases often necessarily follows from the engrossment of the doctor's energies in the primary disease, and is in some cases undoubtedly unavoidable, but whenever possible, prompt attention should be bestowed on that organ which, from a utilitarian as well as artistic aspect, is of such great importance

FRACTURE OF THE CLAVICLE IN CHILDREN

A STUDY OF TWO HUNDRED CASES TREATED BY SAYRE'S METHOD

Presented to the Section on Diseases of Children at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10 1898

BY A E GALLANT, M D
NEW YORK CITY

Of all fractures in children that of the clavicle is most common and presents the greatest difficulty in securing union without deformity

In a surgical service including 18,042 children of 10 years and under, there occurred 343 fractures, of which 172, or 50 per cent, were fractures of the clavicle Of this number, 12 were under twelve months, 112, 1 to 5 years and 48, 6 to 10 years old The youngest was but six weeks old Three cases between 1 and 5 years came to us with faulty union The fracture was located at the outer portion of the middle third, and in most cases there was distinct separation, and knuckling upward of the fragments All were single, simple fractures, with little evidence of laceration of adjacent tissues The line of fracture was more or less oblique, with upward and inward displacement of the acromial fragment Falling on the outstretched hand was given as the cause of the injury

Up to the time when Lewis A Sayre described "A Simple Dressing for Fracture of the Clavicle' (Bellevue and Charity Hospital Reports, 1890), no satisfactory plan which would meet the anatomic conditions had been proposed Since then it has almost superseded all others

Deformity—In reference to the deformity, Sayre says that "all authors agree that the deformity which occurs in the fracture of clavicle is, that the shoulder falls downward, forward and inward, and that the outer end of the sternal or inner fragment always rides over the inner end of the outer or acromial portion of the clavicle" Such a displacement of the fragments has not been met with in the series of cases here reported The point of fracture has been at the outer portion of the middle third, with the shoulder dropping downward, inward and forward, thus dragging on the acromial fragment so as to make an angle or knuckle at the seat of fracture, but the inner fragment has not been found displaced above the outer fragment as described by Sayre and Gray

DISCUSSION

Dr A C **Cotton**, Chicago—In using plaster for the correction of this tendency to deformity, or for any surgical purpose whatever my experience has been that not infrequently you meet a case whose skin won't stand plaster, the continued use of a plaster for even two days bringing out a very troublesome eruption The Doctor did not state, but I suppose a dressing put on for curing this deformity must stay on ten days to two weeks

Dr **Gallant**—The dressing is left two weeks

Dr **Cotton**—Many cases will not stand plaster for two weeks At a certain time of the year you can dress only a few cases in this way Even when the temperature is most comfortable, some cases will not stand plaster Where I can not use plaster I have been in the habit of using a stocking, introducing the hand into the stocking to the very toe of it and carrying the stocking around and attaching a bandage to the upper part of it First having made a collar, by rolling up some muslin, perhaps with some cotton, to encircle the shoulder, I sew the stocking to this collar A "figure eight" bandage brings both shoulders backward, another bandage holding the arm firm I believe that accomplishes all that is claimed by the dressing just presented This dressing is the simplest, I believe, that has ever been devised, but some will not bear it

Dr R B **Gilbert**, Louisville, Ky —In a case of fracture of the clavicle last summer I found the difficulty the Doctor refers to, in a child with a slightly eczematous skin In that case I perforated the mole skin bandage, which is the best bandage to use in such cases In that way you can obviate to a large extent the irritation of the skin, but it does not entirely obviate it It is much better than a pad in the shoulder, which not only causes irritation but presses on the vessels and nerves in the axillary space and often causes swelling and pain so it has to be removed The over shoulder strap is certainly of very great advantage, and it would, it seems to me, obviate deformity The adjustment of these plasters I think should be done under chloroform Otherwise the constant motion prevents proper adjustment of the bandage The anesthesia need be but partial

Dr A **Ernest Gallant**, New York City, in closing—In reference to the irritation, if you use a baby powder and use absorbent cotton in the fold of the arm, which you can tuck in after the arm is put up, the irritation to the outer arm does not amount to much If, as the Doctor says, you wish to use the perforated plaster, you may do so One point in reference to the plan suggested by Dr Cotton is that when you put a child up in a bandage you have got to put it up to stay Last year I showed you how to put up the femur of a child so the child could do anything it pleased The old way was to strap the child down, but in the way I suggested the child can play or do anything it likes I have no doubt the plaster itches, but that we can not avoid I appreciate the difficulty of this plaster, because I have had to use considerable plaster on my own hands and fingers in dressing infective wounds on myself But in any other way the child's arm moves more or less and there is great difficulty in the healing of the fracture I never use chloroform but I use laughing gas for the short operation Perhaps I am not quite so careful as to causing a little pain in children

After I had examined the child and found the fracture of the clavicle, I remembered having measured the child and found the shoulders three inches more in circumference than the head It was a dry labor and I have no doubt I broke the clavicle when I brought the child into the world I did not put any dressing upon it, nor shall I attempt to break it

NEURO-DEFORMITIES IN CHILDREN FROM AN ORTHOPEDIC STANDPOINT

Presented to the Section on Diseases of Children at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo June 7-10 1898

BY JAMES W COKENOWER, A M, M D
Secretary Iowa State Medical Society Professor Orthopedic Surgery
College of Physicians and Surgeons, Medical
Department of Drake University
DES MOINES, IOWA

It is generally conceded that nearly all deformities, especially in children, not traumatic or hereditary, are due directly or indirectly to some abnormal condition of the nervous system This branch, like all other branches in medicine and surgery, bows with obedience to its alma mater, because we can not understand the anatomy, pathology and histology of the nervous system, the cerebro spinal or any other specialized nerve cell, unless we understand general medicine and the laws of cell birth, life and growth

My experience, as a general practitioner, prompts me to admit that nothing is more important than the nervous system and its disorders, and yet there is nothing in medicine in which our knowledge is so deficient In the investigation of even so simple an ailment as headache, the field of medicine must be well examined to know whether the real cause of the pain is vicious heredity, nephritis, lack of exercise, anemia, puberty, menopause, menstruation, masturbation, occupation, or one or more of a myriad of other influences and diseases, all of which it is necessary to know to cure a simple headache How much more then, is it necessary for him who would successfully treat the nervous system, especially to that extent to obviate deformities produced by or through the nervous system, to know thoroughly, not only the nervous system, but the entire human system, and everything that would hinder or augment its normal development. Unless we have such knowledge, we will still find ourselves treating apparent poliomyelitis for scorbutis, rachitis for paralysis, torticollis for cervical adenitis, trismus for an erupting wisdom tooth, and the "knee jerk" for morbus coxarius these being deformities produced by abnormal changes in the nervous system. However, there are some "made to order" ovarian deformities, if I may be pardoned for mentioning the fact, which do not come under the scope of this paper, or any other, in many instances, and would not occur if a better knowledge of the nervous system and its influence over each component part of the human system existed. In many instances poliomyelitis or infantile paralysis in its various forms could be obviated if the functions and disorders of the nervous system were better understood. The remark once made by Prof. Jenner that more mistakes are made by "not seeing than by not knowing," is not without a lesson, and helps to confirm the fact that more mistakes are made in diagnosing than in treatment.

Next to the deformities produced by poliomyelitis or infantile paralysis, are those produced by hysteria, which the consensus of opinion of modern writers on the subject has placed among the diseases of the nervous system, which by no means is the most easily handled. I believe, the nervous system being well understood, that a line of general treatment may be used that will lessen the chances for such deformities and militate against existing ones. For this, the constitutional treatment must be looked after first, and the disease will always indicate same after which the special treatment can be prosecuted and the drugs used indicated by the specialization of the disease. All kinds of talipes, or club foot, wrist drop, rotary lateral curvature of the spine, and, in fact, nearly all the muscular deformities known to orthopedic surgery may be produced by some nerve disease, and to undertake to correct the deformity with surgical means without first endeavoring to ascertain the real cause which produced the deformity, and treating the same medicinally, would not be in keeping with the modern medical and surgical science of the day. To more fully illustrate how easily we may be mistaken in the cause and results of deformities produced by diseases of localized nerves, or the nervous system, I will report the following case which has recently come under my observation.

December 7, 1897, Mr. B. brought his little three year old girl to me for examination, stating that she had a crooked back, which the doctor said was caused by the rickets. Upon a careful examination I found that the child had a decidedly neuropathic family history, and a typic spasmodic rotary lateral curvature, which had been diagnosed and treated for rachitic curvature, and as the diagnosis was incorrect, the treatment must have been, because there had been no change for the better, but rather for the worse, after about six months trial. The further history of the case showed that any kind of excitement or fatigue would increase the deformity, and when in a state of repose or sleep, the spasm of the muscles seemed to lessen. This convinced me that it was a case for medicinal treatment. I gave her a good general tonic, strychnin internally, and locally used inunction and massage and put on a crinoline jacket to support the spine and lessen the fatigue caused by the effort of the child to stand erect. Six weeks later I put her on three drop doses of fluid extract of conium, increasing gradually to thirty drops, and hypodermic injections of atropin. These two drugs have always given good satisfaction in such cases. One month after this treatment began a marked improvement was noticed, which continued, and soon the amount of medication was gradually diminished, and time for same increased, until a little over three months from the time treatment first began, the jacket was removed and treatment stopped, as the spasm of the muscles was a thing of the past, and she could walk erect without support.

WHAT INFLUENCE DO STIMULANTS AND NARCOTICS EXERT ON THE DEVELOPMENT OF THE CHILD?

Presented to the Section on Diseases of Children at the Forty-ninth Annual Meeting of the American Medical Association held at Denver, Colo., June 7-10, 1898.

BY E. STUVER, M.Sc., M.D., Ph.D.
Member Colorado State Medical Society, Rocky Mountain Inter-State Medical Association (Sec.), American Medical Association, International Medical Congress (Berlin) etc. etc.
RAWLINS, WYOMING

Since the earliest dawn of history, there has been inherent in the human organism a longing or craving for something to blunt the keen edge of anguish and sorrow, as well as to curb the intellect and inhibit the will, thereby giving full reign to the sentiments and passions during times of conviviality and enjoyment.

Glancing down through the ages into the dim twilight of the past we behold the Chinese using wine from grapes and beer from rice, somewhat like the present saki of Japan, the Hindus sura made from rice, barley, honey and other ingredients by the common people and soma made from the juice of certain plants, and after fermentation offered as a libation to their favorite Gods, Indra, Vishnu and others by the priesthood and rulers. "The ancient Persian writings, the Zend Avesta, dating back to the period of Zoroaster possibly 4000 to 6000 years B.C., contain, like the Rig Veda, many references to a sacred drink, homa and a popular drink, hura."[1]

The Bible contains numerous references to the use of wine, which was frequently carried beyond the point of moderation. And so down through the ages we find all peoples from the lowest savagery to the highest civilization resorting to some form of intoxication. Here on the one hand we behold the highly cultured lady imbibing her strong tea, the orator or statesman trying to conjure up the shade of Demosthenes or Cicero or the poet to arouse his slumbering muse by liberal potations of wine, brandy or whisky, while on the other hand we see the Guatemala indians fuddling themselves with hemlock sap, the Peruvians with coca, the Tartars with fermented mare's milk and the Algerians with hasheesh.[2]

To the scientist and the philosopher, whose function it is to study the phenomena of nature, search out their causes, trace their effects, and co-ordinate all into a harmonious and symmetric whole, and especially to the physician, who should be a strong combination of both scientist and philosopher, this question appeals with peculiar force. What subtle but res [illegible] impelled races, nations and individuals to give themselves up to an indulgence and debauchery that have inevitably led to their ruin or extinction? What caused the Persians under the temperate Cyrus, who by their hardihood easily conquered the effeminate Medes, to fall victims to luxury and degenerate so that Xerxes, the descendant of Cyrus, the monarch of Asia Minor, with his mighty army, was ignominiously defeated by the hardy and temperate Greek? What, except gross intemperance and its twin sister, licentiousness, so degraded the stern, noble Roman character, reduced his physical power and dissipated his ambition, until from being the ruler of the world, he became an easy prey to the barbarian hordes of the north? What, in short throughout all time and among all nations, has been the result of the use of narcotic and stimulating poisons, save effeminacy, degeneration and extinction? With these indisputable facts of history before us, does it not become our duty as physicians, whose function it is not only to cure disease but to act as the conservators of physical, mental and moral integrity, to investigate carefully the exact physiologic effects exerted by these agents on developed and developing living organisms, and to trace the results of their moderate and excessive use both on the present and future generations?

We shall first consider the most widely used and probably least injurious of these substances, viz, *tobacco* The deleterious substances in tobacco smoke are *carbon*, which acts mechanically as an irritant, and discolors the secretions of the bronchial tubes, *carbonic acid gas*, which tends to produce sleepiness, headache and lassitude, *carbonic oxide*, "a very active, poisonous agent producing drowsiness, unsteady movements of the muscles and vomiting,"[3] and crude nicotine, which consists of nicotine proper, and a volatile empyreumatic substance containing ammonia, and a dark, bitter, resinous extract[3] The ammonia bites the tongue, makes the mouth dry and induces thirst, thereby causing the smoker to drink frequently and exciting a free salivary secretion, it also exerts a solvent influence upon the blood[3] Nicotine proper, produces tremor, palpitation of the heart and paralysis, while the volatile empyreumatic substance causes a sense of oppression, and gives an unpleasant odor to the breath

Concerning the physiologic action of tobacco, Wood (Ther and Materia Med, 6th Ed, p 396) writes as follows "Upon persons who are not habituated to its use, tobacco acts as a very powerful depressant, producing horrible nausea and vomiting, with giddiness and a feeling of intense wretchedness and weakness If the amount taken has been large, to these symptoms are added burning pain in the stomach, purging, free urination, extreme giddiness, passing into delirium, a rapid, running and finally imperceptible pulse, cramps in the limbs, absolute loss of muscular strength, a cold, clammy skin and finally, complete collapse, terminating in death" Nicotine is an exceedingly virulent poison, very small quantities, even 1/30 gr have caused poisonous symptoms in the body (J W Sevier, M D), and large doses almost instant death

Tobacco increases the fluidity of the blood, interferes with the development of and causes disintegration of the red blood corpuscles, diminishes the power of the blood to take up oxygen and give off the carbonic acid,[4] and thereby retards the progressive cell changes upon which the development of the body depends, it produces debility and irregular action of the heart[5] and lowers the tone of the whole circulatory system, it weakens digestion and assimilation, and not only prevents the burning up of waste materials but retards their elimination

On the nervous system, tobacco acts as a depressomotor, producing "languor, feebleness, relaxation of the muscles, trembling of the limbs, great anxiety, and a tendency to faint"[6] It also acts as a cerebral irritant, and interferes with the vasomotor centers of the brain to such an extent that the vessels are unable to adjust themselves to the condition required for healthy and untroubled sleep[7] The power of fine co ordination is likewise decidedly lowered by the drug

Tobacco frequently causes disturbances of the special senses Owing to the irritation of the nasal mucous membrane the olfactory sensibility is impaired, and probably owing to the irritation and congestion set up in the nose and throat, together with central nerve disturbance, the hearing is sometimes lowered, but of all the special senses the sight is most seriously affected, and tobacco amaurosis or amblyopia is a not infrequent result of the excessive use of the drug

While it is fortunately true that these effects which are almost entirely functional, rapidly disappear when its use is discontinued by those who have reached manhood, it is very different with adolescents, in whom the habit of smoking causes impairment of growth, premature manhood, and physical prostration[3] The question as to the effects of tobacco on the growing boy or youth has fortunately been removed from the sphere of sentiment and speculation, and is now settled by careful scientific investigations "From measurements of 187 men of the class of 1891, Yale, Dr J W Seaver found that the non-users of tobacco gained in weight during the college course, 10 4 per cent more than the regular users, and 6 6 per cent more than the occasional users of tobacco In height the non-users increased 24 per cent more than the regular users, and 12 per cent more than the occasional users In increase of chest girth the non users had an advantage of 26 7 per cent and 22 per cent, and an increase of lung capacity of 77 5 per cent and 49 5 per cent respectively These facts in regard to the dwarfing effects of tobacco are corroborated by observations on the class of 1891, Amherst, made by Dr Edward Hitchcock He found that in weight non smokers increased during their course 24 per cent more than the smokers, in increase in height they surpassed them 37 per cent, in gain of chest 42 per cent, and in gain of lung capacity 75 per cent It is probable that alcohol and other poisons have similar effects"[8]

The deleterious effect of tobacco on the muscular system, and in diminishing the powers of endurance is strongly emphasized by the fact that "*stop* smoking" is one of the first injunctions given a young man on engaging in training for a race or game of any kind requiring strength and endurance, because every experienced trainer knows that smoking lowers the working power of the human muscle by a large percentage,[9] and that to smoke merely invites defeat If tobacco so seriously injures the young athlete during a short period of training, how much greater must the injury be in the preparation for the arduous duties of our exacting modern civilization How seriously handicapped is the boy who enters the race of life with every cell and tissue of his body poisoned by nicotine

According to the evidence of teachers and educators all over the civilized world, tobacco exerts a very pernicious effect on the student He becomes dull, lazy and unreliable, and retrogrades in his work Indeed, so marked were these effects that "in France the difference between the students in the polytechnic schools who smoked cigarettes and those who did not, in scholarship, as shown by their respective class standings, was so great that the Government prohibited absolutely the use of tobacco in all government schools[10]" "Out of thirty principals and teachers interviewed by the *Chicago Record*, all were agreed that a low standard of scholarship characterized the boy who habitually used cigarettes[11]" The extended investigations of Dr Seaver, of Yale College Physical Department, and Dr McDonald's studies of school children at Washington, D C, conclusively show that cigarette smokers are more feeble physically and mentally than other students[12] This, together with the fact that a very large percentage of the prize-winners, and men who stand highest in their classes do not use tobacco, ought to convince every unprejudiced person that tobacco is at least injurious to the mind of the developing child and youth We make this statement boldly, notwithstanding the recent symposium of St Louis physicians, and the specious arguments and special pleading of lawyer Garrison in his paper, "A Brief for the Cigarette," read before the New York Medico-Legal Society, in which he tries to create the impression that because a large number of cigarettes examined were made of pure tobacco, and did not contain opium or other adulterants, therefore they were harmless What sophistry! Just as though pure tobacco, which contains a substance far more poisonous than strychnin or morphin, is not in itself sufficiently dangerous! Such attempts as these which try to overthrow clearly demonstrated facts and encourage boys and young men in the formation of a habit which can do them absolutely no good, but may be the source of much injury, both to themselves and their friends, besides being a nuisance to every one not saturated with the vile poison with whom they come in contact, are certainly not based on correct ethical principles, and leave a strong impression that they are stimulated by a *quid pro quo* from the tobacco trust

EFFECT ON THE MORAL NATURE

The use of tobacco has a peculiarly demoralizing effect on the moral nature of the young In addition to making boys tired, stupid and lazy, it makes them irritable, perverse and careless of the rights and feelings of others, besides, in many instances leading to lying and even stealing This tendency to moral degradation is exceedingly prevalent among habitués of all kinds of narcotic poisons, and especially so among those addicted to the use of opium I have seen quite a large number of so-called "*fiends*," and have yet to find the first one on whose word I could rely in a business transaction There may be honest ones, but if so I have never met them

For many years I have been firmly convinced in my own mind that much of the pallor, anemia, malnutrition, and the many evidences of retarded growth and development so frequently seen—especially among the poorer classes of our people, are largely due to the tobacco-laden, poisoned atmosphere which these children are obliged to breathe Many a time have I gone into small, poorly ventilated rooms, where at best it was difficult to get sufficient pure air, and found a child suffering from pneumonia or some other severe disease, so enveloped in the foul fumes of stale tobacco smoke that it could scarcely breathe, and every breath it did take was a poisoned one, and have seen the father, who appearently was very solicitous about his child's welfare, puffing away complacently at an old pipe whose horrible odor ought easily to win for it the place of honor in a tannery or a white lead factory, and while doing more harm than all the science and skill of the medical profession, armed by the whole materia medica, could counteract, would probably be finding fault with his physician and blaming him for the child's slow recovery Nor is this the most discouraging part of the matter, because in quite a number of instances when their attention was called to the evil effects of the tobacco smoke the fathers became angry and refused to believe that it had any such effect Such cases as these show the moral obtuseness that may follow and the utter selfishness that may be engendered by the use of tobacco better than any lengthy theoretical disquisition could possibly do Neither, according to competent authority, is the evil limited to the users themselves, but lingers to curse their descendants "No evils are so manifestly visited upon the third and fourth generations as the evils which spring from the use of tobacco"[13] says Sir Benj Brodie

Let us now consider the effects of alcohol on the human organism Sir Benjamin Ward Richardson tells us that "from the stomach alcohol passes directly into the circulation, so in a few minutes it is swept through the entire system If it be present in sufficient amount and strength, its eager desire for water will lead it to absorb moisture from the red-blood corpuscles causing them to shrink, change their form, harden and lose some of their ability to carry oxygen It may even make them adhere in masses and so hinder their passage through the tiny capillaries" (Diseases of Modern Life)

This attraction of alcohol for water, together with the fact that it coagulates albumen and forms a thin white film on the mucous membranes by acting on the albuminous elements of the secretions, and the peculiar ease with which it penetrates protoplasm (this substance can defend itself against most other poisons), suspends or destroys the action of all the primary organic elements[14] In short, it affects every cell and tissue of the body and as Dr Lionel S Beale tells us, "alcohol does not act as a food, it cuts short the life of rapidly growing cells or causes them to grow more slowly,"[15] thereby preventing their proper development and exerting a particularly injurious effect upon the young, retarding their growth—both mental and physical

EFFECTS ON DIGESTIVE AND ASSIMILATIVE ORGANS

There is a wide divergence of opinion as to the effects of alcohol on the digestive organs Formerly it was almost universally believed by physicians that alcohol in moderate amounts aids digestion, but the careful, accurate and painstaking investigations of recent years have demonstrated the fallacy of that opinion, and at the present time the majority of physicians who have made a careful study of this subject are convinced that alcoholic beverages not only do no good, but are positively injurious to digestion "One tablespoonful of whiskey reduces digestive activity more than 75 per cent" say Drs Chittenden and

Mendel[16] "Nothing more effectually hinders digestion than alcohol"[6] says Dr Richardson "If much alcohol is taken into the system the gastric juice is so changed by its direct action that digestion is arrested,"[17] asserts Dr Bunge "The idea of alcohol in any form being an aid to digestion is altogether fallacious and has brought disease and ruin to innumerable multitudes,"[18] is the verdict of Dr C H Shepard Dr T D Crothers says, "I have never seen a case where spirits used in any form, for any length of time, did not produce derangement and disease of digestion,"[7] and Dr J H Kellogg writes as follows "Nothing could be farther from the truth than the popular notion that alcohol, at least in the form of certain wines, is helpful to digestion " Roberts showed years ago that alcohol, even in small doses, diminishes the activity of the stomach in the digestion of proteids Gluzinski showed ten years ago that alcohol causes an arrest in the secretion of pepsin and also its action upon food Wolf showed that the habitual use of alcohol produces disorder of the stomach to such a degree as to render it incapable of responding to the normal excitation of food Hugounencq found that all wines, without exception, prevent the action of pepsin on proteids, the most harmful are those which contain large quantities of alcohol, cream of tartar and coloring matter Wines often contain coloring matters which at once completely arrest digestion, such as methylin blue and fuchsin "[19] Many similar expressions from the most celebrated physicians in the world might be cited, but the above are enough to show that alcohol even when exhibited as a therapeutic agent, should be used with as much care as strychnin opium, or any other poison, and not in the careless, indiscriminate manner in which it has been used in the past

From impaired digestion there naturally results a deficient supply of healthy pabulum for enriching the blood and building up the tissues All the cells and tissues of the body are surrounded by membranes, on the integrity of which the silent work of building up the body depends "If they are rendered too porous and let out the colloidal fluids of the blood—the albumin for example—the body dies, dies as if it were slowly bled to death If, on the contrary, they become condensed or thickened or loaded with foreign material, then they fail to allow the natural fluids to pass through them They fail to dialyse and the result is either the accumulation of the fluid in a closed cavity, a contraction of the substances inclosed within the membrane, or a dryness of the membrane in surfaces that ought to be freely lubricated and kept apart Upon all these membranous structures alcohol exerts a direct perverting power of action It produces in them a thickening, a shrinking and an inactivity that reduces their functional power That they may work up rapidly and equally the membranes require to be at all times properly charged with water If in contact with them any agent is brought that deprives them of water then is their work interfered with, they cease to separate the saline constituents correctly and if the evil that is thus started be allowed to continue, they contract upon the contained matter, in whatever organ it may be situated, and condense it " "By its effect on these membranous envelopes and coverings, alcohol becomes one of the most extreme causes of the modification of animal function and one of the greatest sources of structural degeneration "[3] "The long-continued presence of alcohol in contact with the membranes destroys their dialysing property and produces in the end organic changes "[8]

This effect of alcohol on the membranous structures exerts à most pernicious influence on the health and development of the body While, as previously shown, its action on the digestive organs impairs the quality and reduces the quantity of the pabulum formed for the nourishment of the tissues, this last action not only interferes with the selective activity of the cells and tissues and the free passage of the nutritive material through their enveloping membranes but at the same time retards that retrograde metamorphosis which is always conjoined with healthy activity, and by clogging the membranes, prevents the free elimination of those retrograde products or toxins which are being constantly formed in the body Nor is this all, for by lessening the oxygen-carrying power of the blood it prevents the burning up of these waste materials and toxins, and thereby interferes with functional activity, besides poisoning the system

Viewed in the light of these facts, the so called conservation of the tissues produced by alcohol, instead of being an advantage, as so generally taught, is, I believe, a matter of very serious import to many a patient With the assimilation of the life giving material impeded, and the elimination of death dealing poisons retarded, the only explanation I can find for the widespread belief in the beneficial effects of alcohol is the tendency of the medical profession to conservatism It is so easy to float with the current, it is so pleasant to advocate those doctrines transmitted by generations of ancestors and which have become so strongly ingrained in our natures as to be a part of our mental being, it is so hard to stem adverse currents and fight against the opinions and dicta of the many, it is so unpleasant to strive against inherited cravings and boldly to determine to make truth our guiding star, that the wonder is that any progress has ever been made But while this is true, and all human progress and advancement are conditioned on the overcoming of these difficulties, the Creator of the universe has implanted in the minds of some rare spirits such a longing for the truth, such a desire to penetrate the arcana of nature, that they boldly face all difficulties, overcome all obstacles and never give up the fight until the banner of truth proudly floats over the innermost stronghold of error I am happy to say that in the solution of this great problem our own Association has taken an active and commanding part, and among the gallant standard bearers none occupies a higher position than the Nestor of our profession, the revered and beloved N S Davis

EFFECT ON THE MUSCULAR SYSTEM

For ages the almost universal impression has been that alcohol gives muscular force, that it enables man to do more work, to undergo greater hardships, to withstand greater cold and heat than he could without it Accurate scientific investigations with the dynamometer and other instruments of precision have, however, positively demonstrated the fallacy of this impression As Dr Bunge has very cogently stated, "thousands of experiments upon large bodies of men have been made and have led to the result that in peace or in war, in heat, cold or rain, soldiers are better able to endure the fatigues of the most exhausting marches when they are not allowed any alcohol A similar result is observed in the navies and on the thousands of commercial vessels belonging to England and America, which put to sea without a drop of alcohol Most whalers are manned by total abstainers '[20] Arctic explorers endure the severe cold much better when they abstain from alcohol than when they use it even in moderation The great business interests of the country are beginning to appreciate the fact that alcohol unfits men for doing the best work So convinced are they of this that many railroads and large manufacturing and mercantile establishments will neither employ nor retain in their employment persons addicted to the use of alcoholic beverages

That alcohol lowers muscular force is very conclusively shown by the fact that those who engage in athletic sports must stop drinking if they expect to excel No prize fighter, ball player, oarsman or any kind of athlete can keep up drinking habits without so injuring himself in a few years that he is relegated to the rear as "a back number' This is understood by all trainers and has impressed itself so strongly, that, even in beer-drinking Germany, the favorite national beverage is being discredited by athletes "It is stated that three clubs of Leipsic students have abandoned the 'morning drinking bout,' and that several additional university clubs are about to take the same step The desire to excel in all athletic sports is said to be the impelling cause of this action on their part" This practical acknowledgement that beer drinking is inimical to the best physical condition and to the highest degree of athletic success would be significant in any country, but is especially so in Germany, the great beer-drinking country of the world Careful experiments made on a number of persons by Dr Kellogg several years ago showed that muscular strength is diminished more than 30 per cent by the use of alcohol, and the same author declares that nothing could be more absurd than the administration of mixtures containing alcohol when tonic effects are desired [19]

The careful and elaborate experiments made on dogs by Prof C F Hodge (*Pop Science Monthly*, April, 1897) showed not only a marked diminution in muscular activity, but a greatly lessened power of endurance on the part of the dogs that received alcohol

EFFECT ON THE SPECIAL SENSES

Careful experimental investigations as well as everyday practical experience have demonstrated the fact that alcohol reduces the power and functional activity of the special senses, besides so perverting the action of the nerve centers and interfering with transmission to and from the periphery, that correct impressions of objective phenemena can not be obtained The acuity of vision is lowered, the power of hearing reduced, the sense of smell blunted and the taste so obtunded that fiery and even caustic liquids can be swallowed without wincing When carried to the stage of complete narcotism the functions of the special senses are for the time being lost and those "gateways of the soul" which are given us for protection are closed, and the man—deprived of sensation, motion and the power to see, hear, taste, smell or feel—lies before us, a mere vegetating mass, with barely enough respiration and circulation to sustain life, and if the narcotism is carried too far these stop too and he dies

EFFECT ON THE NERVOUS SYSTEM

But while alcohol retards digestion, impedes assimilation and excretion, reduces the oxygen-carrying power of the blood, and inhibits the nutrition of the cells and tissues of the whole body, still it is on the nervous system that its most far reaching and malign influences are exerted According to Dr George Harley,[22] it acts on nervous tissue in three distinctively different ways "Firstly, through its chemic action on the blood, second, by disordering the liver's functions and causing the bile to accumulate in the circulation, thereby poisoning the brain and nerves, and thirdly, by its accelerating the heart's action and thus sending an increased supply of blood to the brain'

Dr Norman Kerr[23] writes as follows "Alcohol paralyzes the vasomotor nerves, and thereby relaxes control over the vesels so that these dilate and allow more arterial blood to pass to the brain With this superabundant supply of blood there is great activity of function This is the stage of exhilaration, excitement, brilliancy, sometimes frenzy and delirium Owing to the loss of the contractile power of the vessels the increased blood-supply can not be returned to the veins from the brain with sufficient rapidity, and thus there is a block, causing impediment of the circulation, which ought to be free and unimpeded to allow of duly aerated, fresh arterial supplies, this is the stage of depression—of depression and collapse, when the brilliancy dies away, memory fades, speech is thickened, voluntary movement ceases, sensation is dulled and consciousness fails This process, frequently repeated, sets up permanent tissue changes The covering envelope is thickened and otherwise so injured that proper nutriment can not be conveyed to the brain, and thus that organ is badly nourished The shape of the brain cells is altered, and the physical degradation of the cerebral substances sadly impairs the intellectual and moral faculties"

Dr B W Richardson says "It has four distinct effects on the nervous system 1, simple exhilaration or excitement, caused by paralysis of nerves controlling the supply of blood, 2, muscular weakness or lack of control of one's movements, 3, mental debility, involving the weakening of the will, judgment and reason, 4, unconsciousness, with entire prostration of the body, stupor and delirium tremens," and Dr N S Davis states that "alcohol diminishes nerve force, sensibility and the action of the nerve centers in direct proportion to the amount entering into the blood'

"The excitement of all natural stimulants is not necessarily followed by a corresponding depression, but it is the inevitable result of alcohol and all other narcotic stimulants, that they are followed by depression more than equal to the excitement produced, so that a person using narcotic stimulants is more depressed than ever, and, therefore, is more inclined to repeat and increase the dose" ' And I desire to add that this tendency of alcoholic beverages and other narcotics to create a craving which only *their use* in increasingly larger doses can satisfy, is one of the great dangers connected with their use Time will not permit me even to allude to the many pathologic changes or diseases that result from the excessive or long-continued use of alcohol in any of its many forms Enough has [illegible] ver, to show that it seriously interfe [illegible] ve and lative functions, even in the adult, and how much more serious must its effects be on the growing child or youth, whose normal development is conditioned on the possession of pure, rich, properly oxygenated blood, active assimilation and unimpeded elimination? If it reduces muscular power and activity in the adult, how much more serious must its effects be on the rapidly developing muscular system of the youth! If it reduces the power of the special senses and so perverts sensation and interferes with the ability of the mind correctly to interpret the actual condition of the physical and mental powers in the adult, how great must be the injury it inflicts on the immature muscular system, and how terrible its effects on the nervous system of the growing boy!

EFFECTS ON THE MIND

In view of the foregoing effects on the physical organization, the question naturally arises, How does alcohol affect the mind? What influence does it exert on the immortal part of man? If human experience and observation have ever incontrovertibly established any truth, I believe they have proved that alcohol dulls and perverts the perceptive powers, deranges the emotions, beclouds the intellect and inhibits and paralyzes the will. "The will is always lessened in force and activity. The ability to determine between two or more alternatives, to resolve to act when action is necessary, no longer exists in full power, and the individual becomes vacillating, uncertain, the prey to various passions and to the influence of vicious counsels."[2] "The more purely intellectual faculties of the mind rarely escape being involved in the general disturbance caused by alcohol. The power of application, of appreciating the bearing of facts, of drawing distinctions, of exercising judgment aright and even of comprehension, are all, more or less, impaired. The sense of right or justice, which the individual may have had, is so weakened or destroyed that he will lie or steal or commit murder or other outrages, even where there is no provocation." "The memory is among the first faculties to suffer,"[26] writes Dr. Wm. A. Hammond, and Dr. August Forel of Zürich, says: "The poisoning of the brain by alcohol is all pervasive. We need not descend to the drunkard. In looking at the moderate drinker we see that his sensibilities are less fine, he cares less for the strict truth, he is more negligent of the proprieties and less active mentally."[27] Nor is this all, for "under alcoholic influence the brain begins to think awry. It can not think straight,"[28] and its influence on the psychical processes is curious, for while it renders them much slower, the individual under its influence believes them to be much quicker than usual."[29] Indeed, experiments made in Heidelberg University show that the consumption of alcohol, whether in large or small doses, produces a tendency to paralysis of the mental faculties.[30] And still, many would excuse free indulgence in alcohol on the ground that it is necessary to arouse the mind, to cause thought to flow freely, to stir latent genius into brilliant activity, or awaken the slumbering muse and snatch undying fame from Parnassean heights. Stuff and nonsense! The genius that will not illuminate without alcohol, had better be left to "innocuous desuetude," to take its place with the "mute inglorious Miltons" of the past, and the muse whose celestial fire can only be stirred into an active flame by means of whisky, brandy or even champagne, is at best but a sorry jade, and had better be allowed to slumber peacefully on. If the experience and investigations of the most eminent physiologists and thinkers are of any value, more long-continued, arduous and severe mental work can be accomplished without alcohol than when it is taken, even in small amounts. On this subject Prof. C. F. Hodge writes as follows: "Helmholtz has said in describing his methods of work that slight indulgence in alcoholic drinks dispelled instantly his best ideas." Prof. Gaule once told the writer as an experiment during the strain of his "Staats examen" that he suddenly stopped his wine and beer and was surprised to find how much better he could work. An eminent professor of Leipsic once said that the German students could do twice the amount of work ("Konnten zwei mal so viel leisten") if they would let their beer alone. Dr. August Smith has found that "moderate, non-intoxicant doses of alcohol (forty to eighty c.c. daily) lowered psychic ability to memorize as much as 70 per cent."[31]

EFFECT ON THE MORAL NATURE

As pointed out in the foregoing quotations, alcohol blunts the finer sensibilities and dulls the moral perceptions so that the regard for truth, justice and the rights of others is greatly lessened. Indeed, it is a matter of common observation that old habitués are entirely unreliable, and in many cases their most sacred pledges are utterly worthless. So thoroughly are they in the power of an insatiable appetite, and so absolutely are they enslaved by it, that they would violate their most solemn promises, yea, even, if such a thing were possible, would barter their immortal souls for a glass of whiskey. This, together with the fact that a large percentage of the crimes committed are directly or indirectly due to indulgence in alcoholic liquors, should lead to the most stringent measures to protect the children and youth of our land against their blighting influences. These protecting influences, stimulated by a thorough physiologic knowledge and an aroused conscience, should originate in the home, be continued and strengthened in the schools, and strongly reinforced by the legislatures and courts of our land, and finally should receive the unqualified and earnest support of every physician. When we consider the strong inherent craving for alcoholic beverages in the human race and the powerful inherited tendency (latent though it be) in such a large percentage of persons, I do not believe any physician is justified in using alcohol in the treatment of any case of disease, unless, after a careful investigation, he is convinced that no other remedy will answer just as well. If such a course were conscientiously pursued, I predict that alcohol would soon be reduced to a very limited sphere, because I believe that nearly every disease in which it is now so extensively used could be treated better without it, and the medical profession be spared the odium of producing so many drunkards. The same is true of opium and other narcotic poisons which are now so extensively, indiscriminately and unfortunately—I think needlessly—used. If we would devote more time to securing a clear conception of the great laws regulating physiologic activity, to ascertaining the causes of diseases and trying to remove them, or assist nature in overcoming their effects, instead of merely administering a narcotic dose to cover up the painful symptoms, we would do a great deal more permanent good and not lay ourselves open to the imputation of having done much harm

DISCUSSION

Dr **Slagle** of Minneapolis—In regard to tobacco, the bad effects of it, of course, can hardly be exaggerated The subject brought to my mind an experience I had when I started out in the practice of medicine, about 1861 Among my first cases I had a baby that was very ill On my first visit it had turned suddenly worse The symptoms were all bad sweating almost pulseless, and I at once made an unfavorable positive prognosis that the child was dying I did not observe that a lot of old ladies had gathered in and had been smoking The house was full of tobacco fumes I gave the case up and was going to visit a relative some miles away I returned in the morning and my patient was better, and recovered Then I searched for the cause and found it was the fumes of tobacco with which the room was filled which depressed the child and came near killing it, and caused me to make the blunder in prognosis

In regard to the use of alcoholic stimulants, I do not like to hear Dr B W Richardson quoted, eminent as he was, I think that he went to extremes The more I practice medicine the more I give alcoholic stimulants in certain diseases, and I am sure with good effect Of course, no one can exaggerate the baneful effect of the excessive use of alcoholic stimulants But in the practice of medicine, especially with children, I am sure it is a good therapeutic agent I believe it is, when properly used in properly selected cases, a valuable agent As to its injuring digestion, that is a mooted question, there are good authorities on both sides I am sure it does not always injure digestion I hoped the essayist would speak of opium The more I practice medicine, and my department is diseases of children almost entirely, the more cautious I am of using opiates in any form in diseases of young children Indeed, I use opium very little I may state that in the earlier days of my professional experience I saw great harm from it I am even willing to admit that I believe I killed some with it. It is a very dangerous agent to use in diseases of children, and I find we can get along without it Those of the rising generation are less excusable, perhaps, for its use than we of forty years ago We have now many remedies that were unknown then, that take its place

Dr **Louis J Lautenbach**, Philadelphia—Up to the present time the youngest age of any one who has been found the subject of tobacco blindness has been 19 years of age This afternoon I expect to report a case I saw 13 years of age, and since then I have found a number of cases of about that age and from there on, and I find, from the influence of tobacco on the system, that these cases are very common indeed I for one am very much in favor of the enactment of certain laws in regard to the use of tobacco If we face honestly the two questions of alcoholism and tobacco, we will find that tobacco exerts the greater harm It is not easy to think so, for we have been taught differently We can use alcohol in reason and it will do good, but upon the young I have never seen any case where the use of tobacco has done any good, but I have seen numberless cases in which it has done harm You go through the streets of our larger cities and notice the young boys smoking and you will see certain characteristics caused by the use of tobacco I think before long we will have laws prohibiting the use of tobacco by minors In the case I mentioned, the vision was about 1/5, the patient was a boy about 13 years of age, rather tall, and he had been following the habit about a year His heart's action was very irregular When the tobacco was stopped, the vision became 6/9, showing the influence of the tobacco on the vision I do believe tobacco has not been talked about more because it is one of our pet vices I find it far more difficult to get patients to stop the use of tobacco than to stop the use of alcohol

Dr **John Ridlon**, Chicago—I simply wish to say a word in protest against the universal application of the conclusions in the paper read Of course, the conclusions of the essayist are correct in a measure, but they are incorrect in their general application Now, as to tobacco, I don't know what I would have been had I not commenced smoking at 13 As far as the effect of alcohol on digestion is concerned, it is true alcohol delays digestion, but it is not necessary to conclude therefrom that it is harmful to the individual Delayed digestion often makes more perfect digestion The patient may suffer difficulty from the digestion being completed before the digestive process has ceased There can be no question that alcohol often is an advantage and help in digestion, not because it hastens digestion but because it delays digestion

Dr **R B Gilbert**, Louisville—I heartily agree with every word that has been said here about tobacco I come from a State that boasts of its tobacco and whisky, and Kentucy probably would not thank me for saying a word against tobacco, but I have written against it, and I have not missed an opportunity to speak against it It gave me dyspepsia and everything else until I quit it It reduced my weight to 120 pounds The point the gentleman makes in his paper is one we should pay considerable attention to We should educate the public mind on the evil effect of the tobacco habit on the infants and children of our nation I believe today, sir, that the degenerated condition of the country that is at war with us, is due as much, if not more, to their use of tobacco than to any other one vice they have We should go back to the ancestry to find the cause of the ill effect on the children I have found one or two children of such a family have a nervous temperament, even sometimes to such an extent that they could not follow the ordinary course of the common schools, many of them becoming epileptic That is not all, it has a degenerating effect upon the moral character The average tobacco user defends himself by saying it is a luxury and a pleasure I know old farmers in my country, apparently hearty and hale, although they use whisky, but they are the exceptions I want to say a word about the use of tobacco among doctors, especially those who practice obstetrics [illegible] w a case in w [illegible] ieve the doctor killed [illegible] ving his [illegible] co to resuscitate i [illegible] th was [illegible] co, and he bl [illegible] hild's [illegible] ld's [illegible] to to account for the death No obstetrician knows what moment he may have to use artificial respiration

Dr E STUVER, Rawlins, Wyo, in closing—I fully understand the fact that tobacco may have its proper usage, I believe, however, that the proper use of tobacco is in the exceptional case, and not in the general rule for mankind Tobacco should not be used by the young Of course, my discussion took up the general physiologic effects of tobacco But the special application is that in the growing boy, tobacco retards growth not only of the muscular system and the nervous system, it not only interferes with digestion and impedes the elimination of toxic products from the system but it interferes with the whole development of the child in every particular, morally and intellectually as well as physically If I had the time to complete my discussion of the alcoholic question, some of the reasons would have been seen for my objections to alcohol, especially for the young We see many of the effects of alcohol in the young not due to its direct use, but due to the use of alcohol by the ancestors While I am glad to know one of the gentlemen claims to get good results from alcohol, yet the more I practice the more I find I can get good results without alcohol I can get better results from strychnia than from alcohol, in a case of pneumonia or any other condition of lowered vitality

GASTRO-INTESTINAL CHOLERIFORM CATARRH

Presented to the Section on Diseases of Children, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo, June 7 10 1898

BY EDWARD L DAVID A B, M D
Assistant to Professor of Diseases of Children Prosector of Anatomy Assistant Demonstrator of Anatomy in the University of Louisville, Medical Department
LOUISVILLE KY

Of the various titles, as cholera infantum, infectious diarrhea, choleriform diarrhea, summer diarrhea, summer complaint, acute mycotic diarrhea, by which this disease is known, none are as expressive as gastro-intestinal choleriform catarrh, for none designate as much at the outset, of the extent and character of its manifestations or variety of its action, summer complaint and summer diarrhea especially should not be used, they being indefinite and meaningless The tendency of giving a number of names to a single disease should be overcome, be simple and comprehensive so no misunderstanding will be possible, avoid a variety of synonyms, they are confusing to physicians in general, who have not this knowledge at their command—knowledge which is tedious and unnecessary, and often leading to serious mistakes

Gastro-intestinal choleriform catarrh, while not of common occurrence compared to other diarrheal disorders, is relatively frequent in children under 2 years of age, is of short duration and frightful severity Occurring as it does in children of such a tender age, weak and easily overcome, it is incumbent on us to know it thoroughly, recognize it early, that we may treat it vigorously and properly It is now generally accepted that the exciting cause of this disorder is bacteria, the exact nature of which is undetermined, whether introduced into the system with impure food or residing in intestines, and made capable of exerting their destructive processes by being transformed into pathogenic germs or forming ptomains is a question to solve, on which our energies should be directed Accepting that bacteria is the cause, we are certain that their action is limited to certain periods of the year, not exerting their influence during very cold months—of twenty six cases none occurred during December, January nor February—on the other hand, the prevalence of the disease during June, July and August would tend to the belief that during a high temperature, the bacteria are especially numerous or active, or changes in the body are such as to especially invite their inroads Dr L Emmett Holt, in his splendid work, "Diarrheal Diseases," draws the inference that "it is not the bacteria directly which produce the lesions, but their ptomains, and, further, that the action of the latter is principally on the blood-vessels" Assuming Holt's inference to be correct, as from our present knowledge it appears to be, what are the causes predisposing to the formation of the ptomains?

Knowing that bacteria exist in the intestinal canal in health, without detriment to normal conditions, anything which changes the healthy tissue or otherwise forms a medium for their development or action would be a predisposing cause

That there is a distinct connection between occurrence of this disease and condition of temperature can not be questioned, occurring only during warm periods and absent during very cold establishes beyond doubt such a relation, whether it is the life of the germ, the normal resistance of the child, or that food undergoes putrefaction to a much greater degree, or that increase of unhealthy surroundings favor the micro-organism, is yet to be decided My observation of twenty-six cases were as follows

April 1, May 1, June 5, July 10, August 6, September 2, October 1

According to the age the cases occurred as follows First six months, 2, second six months, 7, third six months, 9 fourth six months, 5, between 2 and 3 years, 3

There are several reasons for frequency in infancy, one which is seldom emphasized being the natural tendency—from weakness of a child of such a tender age—to succumb to the inroads of any irritant or its inability to resist an irritant But standing above all other causes excepting bacteria, is that old enemy of the infant, which seems to wax stronger as time goes on—improper feeding, it is worthy of note in this connection that the child so fortunate as to be nourished at the breast escapes this dread disorder, with rare exceptions Reasoning from this fact, what is more probable than that food is the vehicle by which bacteria are introduced, a nidus for their development, or causes changes in the mucous membrane favorable to their action? For instance, in over-feeding, the organs of digestion are overtaxed by the increased work and their power gradually diminished, there remains in the intestines a quantity of undigested food which undergoes decomposition, irritating and causing a change in the normal state of the intestines, and a culture in which the bacteria may produce their evils There is scarcely an infant which is bottle fed that escapes diarrhea during the first two years of its existence Improper food of any kind, over-feeding, unhealthy source of obtaining milk, are self-evident reasons for this, meats, vegetable, fruits, are common causes and should be prohibited, because the infant is unable to digest such food We should carefully guard against all irritating ingesta, animal or vegetable, and more so, if not strictly fresh, the ptomains may be introduced in the food and not formed in the intestines, though the latter appears to be in general the modus operandi In conjunction with other results of high temperature the difficulty of obtaining pure milk rapid decomposition of food, and the desire for more liquids on the part of the child resulting from excessive heat, should be borne in mind

One other fact in this connection of feeding, one which was first called attention to by Dr R B Gilbert the sexual act causes colostrum to be present in milk this is irritating, difficult to digest, and has a laxative effect, in two cases I could trace cause to no source except this Pregnancy and menstruation in mother nursing child may cause diarrhea, indiscretion in eating or medicines to mother, the latter may also be the cause in the child, a laxative to overcome constipation continued too long is more commonly a cause than generally credited

Unhealthy surroundings predispose by increasing the liability of contamination of food and drink, or rendering child less capable of resisting by the impoverished air impairing the blood to a greater or less degree, and to the fact of the freer contamination increasing number of bacteria or forming ptomains Dentition is an exploded cause, excluded by the occurrence of this disease mostly in warm weather and seldom in cold, while if it was causative the disorder would be met with at all times without regard to season or temperature Sudden exposure to cold would only act by lowering the standard of resistance, in itself it would be no detriment as far as this trouble is concerned

Any disease present may predispose to this diarrheal affection in like manner to surroundings, by placing the system in a more receptive condition to accept the contagion This form of diarrhea often follows other and slighter intestinal disorders, the reason for which is apparent, the local irritating effect of the milder form being prone to render the mucous membrane of intestines more or less unhealthy and particularly affected by the action of the bacteria

It is unfortunate that there is so little definite knowledge of the anatomic changes occurring, for a disease is best studied in relation with its pathology, there are but few cases that are reported and these only partly satisfactory This lack of facts is due chiefly to the rapid course of the disease with but slight changes compared to intensity of symptoms, the disability to obtain consent for postmortems before cadaveric changes occur, or to different modes of beginning of the disease There would necessarily be a different state of the gastro-intestinal tract in a case following a previous diarrhea to that in which this disease is independent of any other form of trouble According to Rilliet and Barthez the following is a summary of the anatomico pathologic changes divided in four states, *a* ' either the stomach is softened without any lesion of digestive tube, *b*, or the stomach is softened at the same time that the mucous membrane of the intestines, and especially the follicular apparatus is diseased, *c*, or, the stomach is healthy, while the follicular apparatus or the mucous membrane is diseased, *d* or, finally the gastro intestinal tube is not the seat of any lesion appreciable to our senses in the present state of our knowledge, or it presents lesions so insignificant that they are not sufficient to explain the gravity of the symptoms "So far, the disease resembles all the catarrhs but what is special is the abundance of serous secretion and the disturbance of the great sympathetic nerve ' The salivary glands are especially affected, becoming enlarged and micro organisms are found, which however indicate but little, as bacteria abound in the intestines in health If the disease lasts longer than usual there are more decided changes, proliferation of cells in the glands which open on the surface and also from the ductless glands, the degeneration of the epithelium resulting in erosions which expose the basement membrane, or if the disease is protracted, loss of substance is still greater, forming follicular ulcers, if it has lasted a long time a hyperplasia of the connective tissue with thickening of the mucous membrane or formation of mucous polypi May have cysts formed by an agglutination at the orifice of a follicle Of the changes in other organs nothing has been noted save in blood, there is decided lessening in the quantity of the blood and in its solid ingredients, resulting in the terrible anemia which occurs so speedily, also may have evidence of hypostatic congestion

However, the changes in a typic case of gastro-intestinal choleriform catarrh, to our definite knowledge, are those of an acute catarrhal inflammation Generally a child has a diarrhea and little attention is given it, perhaps four or five actions in the day, when, without warning, it is seized with vomiting or the stools are greatly increased in number, and the character changed to that peculiar sort which typifies this disease Or, less frequently, the characteristic diarrhea begins suddenly—at first the stools having a little fecal matter in them, but soon they change to the rice-water discharges similar to those occurring in Asiatic cholera, these are colorless, generally odorless, serous in character and of large amount, occurring twenty to thirty times or even more in a day If the stomach is chiefly involved vomiting precedes the diarrhea, but generally the intestinal symptoms occur first The vomit consists first of the contents of the stomach, or any food taken, then is slimy, containing mucus and serum, and finally, from retching, biliary matters are regurgitated and vomited

In all my cases these two symptoms occurred, the intestinal one generally coming first, at times the two together, exceptionally the vomiting first Intense thirst from drain on blood-vessels, colicky pains, tenderness and retraction of abdomen, often rumbling in bowels Child restless, depressed, irritable, refuses everything save cold drinks, which are almost immediately vomited, pains in muscles, especially of neck Voice weak and hoarse, tongue at first coated, following diarrhea is very dry rapid and great emaciation, sunken eyes with lids partly open, face pale, skin loose, with prominence of the bony points of the body, extremities cold and moist Pulse is extremely rapid, from 140 to 175 per minute, weak and irregular, may be impossible to count finally may become so small as to be imperceptible Respiration is increased in frequency labored and irregular Temperature varies from 103 to 107 degrees in typic cases

If the case terminates fatally, child has convulsions urine scanty or suppressed marked stupor, pays no attention to surroundings, face cyanotic, cold, clammy skin, fontanelles sunken, pulse imperceptible, respiration accelerated and shallow hyperpyrexia generally, but may be subnormal temperature, state of coma In favorable cases there is a gradual abatement of the symptoms, may become an ordinary diarrhea or merge into a decidedly inflammatory one, first vomiting ceases, then change of stools, becoming more fecal in character There is seldom recovery after the more severe, especially cerebral symptoms occur

The prognosis is decidedly unfavorable depending on age, surroundings previous health, whether bottle-fed or by breast; and especially on severity of attack Of the twenty-six cases which I reported seventeen died, or about 65 per cent The duration is generally from twenty-four to forty-eight hours As to diagnosis there can be no doubt There is no disease which presents this marked group of symptoms in the brief time that this does, other diarrheal affections which simulate this run a much longer course, Asiatic cholera is differentiated by its longer course and presence of comma bacillus

Treatment —If possible, a child not breast-fed should be taken to the country during the summer months, or daily to the parks which are to be found in every city of any pretensions The room should be large, well aired, of an even temperature, in which the child is kept, no foul-smelling articles of any description should be left near the child, all vomit and discharges destroyed, preferably by burning The diet should be carefully chosen and carefully given, a suitable amount at regular intervals, above all, avoid overfeeding and restrict to a milk diet, previously boiled if possible, in those in which milk disagrees, barley is an excellent substitute, boiled, strained, and with a pinch of salt added, but as little food as possible should be given during the acme of the disease Any derangement of stomach or bowels, however slight, should be promptly and vigorously treated, bearing in mind that in the generality of cases gastro-intestinal choleriform catarrh follows a milder form of diarrhea In children nursed at breast the mother must be forbidden to nurse the child within three or four hours after coition, as colostrium is likely to excite a diarrhea

From violence of symptoms, rapidity of course and unfavorable prognosis, the indication is decided treatment from the onset, the child should be seen every hour, or better, if possible, for the physician to remain at its bedside during the height of the disease, or for as long a time as his other duties will permit, often immediate attention turns the tide to a favorable course and he may be able to save the little sufferer, it is my custom, whenever applicable, to remain with the patient the entire night and as much of the day as time will allow For the vomiting paregoric, creosote, iced champagne or brandy by mouth, or if vomited, by rectum, if this is unsuccessful a hypodermic of morphin may be tried—but is contraindicated after the symptoms of collapse begin In addition to vomiting opium is good for the diarrhea, restlessness, pain and tenesmus, but should be stopped if drowsiness comes on For the diarrhea, bismuth has given by far the best results, it is an antiseptic and an astringent—two qualities which serve our need especially, opium by lessening peristalsis, lime-water or some other alkaline to neutralize the acidity, pepsin to aid digestion and prevent decomposition of food and formation of gases and acids

The only method I ever adopt of reducing temperature is by cold baths or applications—place child in a bath a few degrees below that of the temperature of the body, and then by addition of ice the water is cooled a few degrees, being satisfied with moderate improvement in this regard This is the best and safest plan, fever is reduced thus only a short time, and the baths should be repeated as often as indicated by a hyperpyrexia

For the pain and tenesmus the application of counter-irritation is valuable, as it lessens amount of medicine necessary to be given internally a piece of flannel folded four times and large enough to cover abdomen is dipped in hot sweet oil or lard, to which about a half a teaspoonful of turpentine has been added, and applied, covered with oiled silk and a cloth, is an excellent method A remedy which has proved of great value to me in these cases is creosote, it is carminative, antiseptic, astringent, is sedative to mucous membrane of the stomach (acting on terminal nerve filaments probably), indications which it is necessary to meet, I give it in one drop doses every two hours combined with bismuth, pepsin and paregoric For nervous irritation or cerebral congestion bromid of potassium is good, but must be used cautiously lest it excite more violent vomiting, it being decidedly irritant in some cases For threatened collapse nothing equals whisky or brandy, ten to twenty drops per hour, in addition to this hot baths with addition of mustard, injections of camphor and atropia, the latter especially if the collapse is threatened from the heart

It is best to give whisky or brandy throughout the disease frequently, if not tolerated by stomach give by hypodermic method, I have used alkaline solutions and, I believe, with benefit, hypodermatically, a 1 per cent solution, or per rectum, 3 or 4 per cent solution We can not be too careful during convalescence A slow, gradual increase in the amount of food, given either predigested, or better, with a digestant and an antiseptic The following formula has been of the greatest benefit during the acute stage of this trouble, before stupor comes on or collapse is threatened

℞	Creasoti	m xii	|070
	Tr opii camph	℥ ss	15|50
	Bismuthi subnit	ʒ iii	11|66
	Pepsini scalæ	ʒ i	3|88
	Syr Aurantii cort	℥ ss	15|50
	Aquæ menth pip , qs , ad	℥ iii	93|30

Mix Sig *Teaspoonful every two hours to a child one year of age*, vary with age and severity of symptoms

In conclusion, I wish to emphasize several points Move child to country during warm months whenever possible, especially if under three years of age Do not think it necessary that food be given during height of disease, it is better to give no nourishment for twenty-four hours than to risk aggravating symptoms Be in almost constant attendance on patient Give stimulants from the beginning, but no opium if least sign of stupor present, especially not hypodermatically The strictest hygiene must be observed

---

IS THE USE OF THE TERM "TYPHOID PNEUMONIA" JUSTIFIABLE? A CASE IN POINT

Presented to the Section on Diseases of Children, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10 1898

BY H D TULEY, M D

LOUISVILLE, KY

The title of this paper was suggested by the following case, the postmortem findings of which made the original diagnosis recorded incorrect

The child was a robust girl, 13 years of age, seen first on Jan 30, 1898, she having had a chill on the two previous days, with a maximum temperature on the first day of 101½ degrees and on the second day 103½ From this time to the eleventh day, all of the symptoms were those of typhoid fever, and the diagnosis was so recorded There had been a general malaise for several days before the first chill, the headache was quite severe, gradually improving as the second week approached, the tongue was heavily coated a brownish yellow, with red edges and tip, but was moist, slight abdominal tenderness at first low down and a little to the left of the median line, right sided tenderness with gurgling soon developing, dry skin, epistaxis, cough quite severe and annoying at times, moderate temperature, from 101 to 102, pulse 120 to 125, rose colored spots appeared about ninth day, typic diarrhea during second week

On the tenth day the temperature rose one degree, the pulse to 140 and the respiration to 50, but the chest still negative Frequent examinations carefully made had up to this time failed to reveal anything abnormal On the twelfth day signs of consolidation were found in the right base near the angle of the scapula, this gradually extending until the most of both lungs were involved Despite free stimulation, administration of strychnia and nitroglycerin, and free administration of oxygen, her condition gradually became worse and she died in the state of severe cyanosis on the nineteenth day of her illness

For four days before her death there was a severe diarrhea, which rather tended to strengthen the original diagnosis of typhoid fever, complicated by a pneumonia

Autopsy three hours after death Lungs almost completely consolidated, save a small area along the anterior borders of both A small area of pleuritic adhesions was found at the left apex posteriorly Spleen was normal, liver also Intestines pale, with some distention of the upper ileum, the lower portion being collapsed and empty The small gut was entirely normal, save a very slight evidence of congestion about the lower one third Enlargement of the mesenteric glands of the lower ilium, none however larger than a pea Colon normal Bacteriologic examination of the lungs showed presence of diplococcus pneumonia, with no other organisms present

In the recent literature on the subject of typhoid fever, by several authors, notably Osler, a great deal of stress is being laid on the occurrence of typhoid fever without intestinal lesions In the case just related many of the symptoms pointed to a typhoid fever, enough certainly, unconfirmed by the Widal test or diazo reaction, which were thought unnecessary in view of the symptoms present, yet no lesions save slight mesenteric gland enlargement were to be found in the abdomen

As to the pneumonia The child was seriously sick for ten days before any signs were apparent in the chest, and no symptoms save the cough that would lead one to think of pneumonia, an annoying symptom which is frequently present, in the writer's experience, in typhoid fever occurring in children* The question to be settled, and which I trust will be brought out in the discussion is, was this a case of typhoid fever—*sine* intestinal lesions—complicated with pneumonia, was it a case of continued fever with a coincident pneumonia, was it a central pneumonia from the beginning with manifestations in the chest delayed until the eleventh day, or shall we class it as a typhoid pneumonia?

Osler states that "the term typhoid pneumonia is commonly used to designate cases with adynamic symptoms and it is to be distinguished from those cases in which typhoid fever begins with a definite pneumonia, the so-called *pneumo-typhus* of foreign writers ' Tyson refers to typhoid pneumonia in the following "The term typhoid pneumonia is one in common use by many who have no definite notion of its meaning, and, like the term typho-malarial, has occasioned confusion In the first place the case may begin as a lobar pneumonia, the intestinal symptoms appearing at the end of the first week or later, at which time also the spots may appear, establishing the diagnosis, while the usual crisis of pneumonia fails to make its appearance Again, a pneumonia may supervene in the second or third week of typhoid fever as a complication in which the true relation is less difficult to determine Finally there may be a true pneumonia, to which stupor a dry tongue, and generally adynamia may be added, without the distinctive lesions of typhoid fever This is true typhoid pneumonia which it may not always be possible to separate from the typhoid fever beginning with a pneumonia Both of the forms of pneumonia may be caused by the typhoid bacillus or the pneumococcus '

Many interesting points are suggested by the history of this case which would perhaps enlarge the scope of the discussion, as the use of oxygen in pneumonia, hydrotherapy, etc, but these points have been purposely omitted by the writer that this one may be the more fully discussed Is the use of the term "typhoid pneumonia" justifiable?

It occurs to the writer that its use in the case related, in light of the symptoms and postmortem findings is justifiable, and should be limited to such cases, but without a postmortem the term should be used with caution and extreme discretion

DISCUSSION

Dr Slagle of Minneapolis—My experience has confirmed my first teaching in the University of Louisville that we have typhoid pneumonia, properly so called, and that we have typhoid fever with pneumonia I have no doubt from the very good history Dr Tuley gave of that case, that it was originally a case of typhoid fever, sine lesions of the intestines, which can occur, the pneumonia supervening later on, that it was not a case of typho pneumonia, although I believe that is a proper term I have seen made cases of typhoid fever, with pneumonia supervening In regard to the diagnosis of typhoid fever in young children My experience is that it is one of the most difficult problems in diagnosis to at all times correctly diagnosticate typhoid fever in young children There are a number of very good physicians who dispute that very young children ever have typhoid fever I am sure I have seen at least two cases of typhoid fever in infants, one about a year old and the other about eighteen months They both occurred during an epidemic of typhoid fever in our city, Minneapolis We had between four and five hundred cases of genuine typhoid fever in Minneapolis The remarkable part of it was that it was an epidemic of typhoid fever during what is supposed to be the healthy season of the year, the only instance of an epidemic of typhoid fever that I have seen in the winter time We did not succeed in finding the cause of the epidemic Some attributed it to the water, but that was not proven to be the cause, at least many of us were skeptical about that There were some cases of typhoid fever in quite young children One case I was called to see, which others had seen, and the point hinged on the diagnosis I am satisfied from the symptoms present and the way the case ran that it was a case of genuine typhoid fever in a child twelve months old, whose mother had just recovered from typhoid fever and had been nursing it I have found it one of the most difficult things in all the field of diagnosis to make a definite diagnosis of typhoid fever, at least anything like early, in young children, and to differentiate it from meningitis or from influenza or from certain bowel troubles

Dr J P Crozer Griffith, Philadelphia—Some of you who have been reading the papers know that Philadelphia has the great honor of having about four or five times as much typhoid fever as any other city in the United States During the past year we have had a shocking epidemic of it I am quite thoroughly convinced that typhoid fever is much more common in young children, even in infants, than it is ordinarily supposed to be The New York physicians, at least many of them, have taken the ground that it is very rare Northrup has never seen the lesions of typhoid fever in children Recently, I had the pleasure of carrying the war into the enemy's camp, when I lectured to Dr Northrup s students in the hospital on this subject, and narrated many cases I have seen I have seen typhoid fever in a child three months old, which is the youngest I have known The youngest case heretofore reported was recorded by Gerhardt a number of years ago in a child three months old The child was in the same room with its mother, who had typhoid fever, but who did not nurse it all, and it had the usual symptoms of typhoid fever I have seen typhoid fever at twelve months, twice at nineteen months, and several times under two years Many of these cases were corroborated by the spots and spleen, and others by the blood examinations repeatedly made I saw a child last winter, of two years, with the slight lesions of child's typhoid Two physicians of Montreal have recently written an interesting article in the Montreal *Journal*, recording nine cases which they could recognize as undoubted cases of typhoid, yet there were no lesions of typhoid fever A curious thing is that in fetal typhoid fever there are no intestinal lesions There were about ten cases of fetal typhoid fever reported before the recognition of the Eberth bacillus became general, that is, before you could differentiate it well from the colon bacillus You know many mistakes at first originated in the differentiation between the Eberth bacillus and the colon bacillus Up to the time of the possibility of the clear differentiation between these organisms, there were only about ten cases, and since then there have been about nine cases of undoubted fetal typhoid fever, the children born from typhoid mothers, all dying before or after birth, and in all cases the Eberth bacillus was differentiated In every one of the nine cases there was a total absence of lesions in the intestine The mesenteric glands, of course, were enlarged I am very skeptical about the diagnosis of the case reported by Dr Tuley as typhoid, simply because the symptoms were so developed I have watched closely these cases of slowly developing symptoms of pneumonia a number of times until the crisis occurred

Dr **A C COTTON**, Chicago—I do not see any objection to the term typhoid pneumonia as expressing a complication of typhoid fever I don't see what objection there would be to typhoid bronchitis I remember looking the matter up very carefully a number of years ago in the preparation of a paper read before the Chicago society I took a hundred cases of typhoid fever, selected only on account of the complete nature of the histories Two thirds of them were from hospital records, the remainder from private practice, and 68 per cent of those cases showed positive pulmonary lesions, from mild bronchitis to pneumonia I do not know what harm there is in saying typhoid bronchitis as indicating a bronchitis complicating typhoid fever I do not know that we should attach any significance pathologically to the co existence of typhoid fever and lobar pneumonia, but I think that is a convenient way of designating the complication If it be indisputably a case of pneumonia, the presence of pneumococcus being demonstrated at the start, and the devolpment of unquestionable typhoid fever following, it would seem better to call it pneumo typhoid

Dr **H M McCLANAHAN**, Omaha—I think if we gave more attention to the matter we would find more cases of typhoid fever in children When we recognize that much of the typhoid fever comes from milk, there is no reason why the child should not be exposed more than the adult There is no reason why its intestinal tract should not be more susceptible My experience is that typhoid fever in children is comparatively mild in the majority of cases Perhaps, first and most frequently, it is mistaken for malaria In this day, with the aid of the microscope, that is hardly necessary It has been said that a case of malarial fever that did not yield to quinin in a week was not malarial fever Another fact I have observed is that the rose colored spots do not remain as long in typhoid fever in children as they do in adults, and sometimes we overlook them They are not as numerous and prominent, and are more evanescent in character Constipation, rather than diarrhea, is the rule in typhoid fever of children So less importance can be attached to diarrhea in making the diagnosis than is true in the adult I saw a child in which a diagnosis of meningitis was made, and I think it may be stated that the symptoms of meningitis, with high fever, closely simulate those of typhoid fever Meningitis, I think, is rather rare in children, except where it is secondary to ear trouble or something of that kind In most cases, we may expect the cerebral symptoms to be very prominent before we can make a positive diagnosis I think there is no doubt typhoid fever is more common in children than the older practitioners have been led to believe I know many doctors prescribe for a child without having it undressed to examine it

Dr **EDWIN ROSENTHAL**, Philadelphia—The question was: "Is the use of the term 'Typhoid Pneumonia' justifiable?" I take the stand that "typhoid pneumonia" is wrong, wrong in every respect I can not conceive that there should be two diseases under one name The cases of typhoid fever I see are, perhaps, the worst that can be seen in the city During the last epidemic I saw some cases in which the temperature was subnormal, the temperature falling to 96 degrees, and one case remained for one week at that degree and then rose and took its usual course If a case of typhoid fever becomes complicated with pneumonia, the pneumonia is only an addition to it If a man tells me he has a case of typhoid pneumonia, I do not know whether he means that he has a typhoid fever complicated with pneumonia or a case of pneumonia that has fallen into a typhoid state

Dr **HENRY E TULEY**, Louisville, in closing—At first we were puzzled to make the diagnosis, the rose colored spots appearing, then pneumonia following, and the fact that on postmortem we found no lesion in the intestine was interesting I think it is clearly understood that the prefix "typhoid" in the term "typhoid pneumonia" refers only to the typhoid state and not to a typhoid fever I think we should use it very carefully, and preferably, not at all I appreciate what the chairman said about diagnosticating late pneumonias, where the signs are difficult to find although a careful examination of the chest is made I think we should only use the term "typhoid pneumonia" when we mean the typhoid state which has developed in a case of pneumonia

---

AUTO-INFECTION VERSUS TYPHOID FEVER AS SEEN IN YOUNG CHILDREN

Presented to the Section on Diseases of Children, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10 1898

BY W C HOLLOPETER, M D
PHILADELPHIA PA

An irregular type of fever incident to auto infection is frequently found in artificially reared children It is also encountered in young adolescence, and may be found in breast-fed children of irregular habits When associated with a depressed system or unhygienic surroundings the fever is most likely to assume a more protracted and intermittent type When found in breast-fed children, the fever is suddenly ushered in at a high grade (103 to 104 degrees), very frequently sustaining this elevation of temperature for several days, when it may break into an intermittent form The fever associated with intestinal toxemia has many times led to the diagnosis of typhoid fever, from which it can only be discriminated in young children by a careful analysis of the various symptoms, conditions and surroundings, diet and exposure and all the many complications incident to artificial management

The clinical picture of a child suffering from auto-infection so closely resembles those many reported cases of typhoid fever that I will attempt to discriminate between the symptoms of these two forms of fever

In early life, the period prior to six months, excessive or improper food is usually rejected by vomiting, and consequently we do not, as a rule, find many cases suffering from acute milk poisoning, except from atmospheric causes, but shortly after this age, when the food enters the intestinal tube more freely, irregular and improper feeding finds its primary manifestations in a mild degree of irregular fever The more intense expressions of auto intoxication may even culminate in a severe form of nerve paralysis, as illustrated in mid summer diarrheas It is in the milder classes of cases, however—not in those of severe acute milk infection, as seen frequently during hot weather, nor in the wasted infant approaching general atrophy —that we meet our most troublesome problem in differential diagnosis

The true clinical picture of auto intoxication is most frequently found in young children suffering from a prior existing chronic intestinal catarrh Children who have recently passed through any of the exanthemata are more prone to inherit intestinal indigestion from these eruptive disorders and hence are more likely to contribute common examples of acute auto infection At the end of the first dentition, if this has been accomplished under dietetic difficulties and unfavorable environments, it will offer the period of greatest frequency The general physiognomy of a child to assume this type of fever is suggestive of the many internal pangs through which it has passed, the child bears the marks of disturbed nutrition, the circulation is usually poor, hence the surface will be found cool, especially the hands and feet, the skin is dull, perhaps harsh and dry, probably earthy or yellowish The child is more likely to be languid than irritable The discoloration under the eyes is quite marked, pink in young children, darker in older To this general physiognomy of a young child suffering from this predisposition, we often have superimposed, sudden, acute excerbations due to some recent dietetic errors, or probably some emotional or climatic disturbances, according to the temperament of the individual, as illustrated in the following cases

Case 1—Harold, aged 6 An unusually healthy child of healthy parentage Normal labor Had for some days looked pale, appeared languid and constantly irritable, gastric irritation pronounced, associated with heavily furred tongue One morning he ate a breakfast of heavy food very rapidly, at noon complained of headache, and during the evening was feverish, having a temperature of 102⅘ degrees Following morning he seemed better was cheerful and lively, attended school until noon Toward evening, however, fever returned with temperature 102¼ degrees again The next morning temperature fell to 100 Complained of headache greater part of the day, though sponged two or three times Fourth day, temperature 100 degrees, much more comfortable, no headache, temperature in the evening 102 degrees Fifth day, severe headache early in the morning Evening, temperature 100 degrees Injection of glycerin and warm water, followed by a large bowel movement Thorough irrigation with warm water and bicarbonate of soda removed a number of hard cheesy masses Succeeding this the temperature was 99 degrees, much more comfortable Evening temperature reached 102⅗ degrees At this period he commenced to vomit Seventh day temperature was normal, evening temperature was 101⅖ degrees Eighth day the morning temperature was 99 degrees, evening temperature 102 degrees Ninth day, morning temperature 99 degrees, noon temperature 102 degrees

The case thus outlined ran forty-nine days of elevated temperature, associated with delirium, alternating with profound stupor, unconscious bowel movements, irregular heart action The boy had nose-bleed, rose colored spots, and assumed most strikingly the general physiognomy of typhoid fever I believe that the *prior-existing intestinal catarrh* was *provocative* of an acute intestinal infection, producing a decided impression on the system, benumbing the reflexes and locally exciting an inflammation of the small bowel He gave negative response to Widal's test

In striking contrast to the above history of a prolonged auto-infection fever, permit me to briefly outline what I believe to be a case of typhoid fever in a child of one year

Case 2 —A B, 1 year old, breast fed, an unusually well developed child, weighing at the time of the commencement of his illness about twenty pounds, having had none of the eruptive fevers, and but slight disturbance incident to the cutting of the six incisors The general regimen of the child was up to this time unusually favorable The family had recently moved into an old house where the plumbing was not up to the highest sanitary model The child was apparently well up to the day of seizure He was ill but a few hours I found him with a temperature of 105 degrees, loose bowels, moderately distended abdomen, slow, irregular pulse, respiration quickened, general disinclination to be disturbed, photophobia The fever sustained this height, varying from 104 degrees to 105⅕ for ten days, when it quickly, within twenty four hours, reached the normal without any subsequent recurrence The child, at the end of the second week, or four days after normal temperature had been reached, seemed perfectly well and happy The blood gave a positive Widal test for typhoid In this case we had vomiting, loose bowels, five to six per day, not necessarily offensive, evidence of imperfect digestion was present, but no masses were voided We failed to find the rose colored spots, the abdomen was soft and slightly painful, the spleen was undoubtedly enlarged, the tongue dry no nose bleeding The case seemed to be more of the cerebral type, as the sphincters lost their control, yet we had no subsultus, and the case closely resembled a meningitis

The diagnosis of the case rests on the continued fever, tympanitis, enlarged spleen, and last, and probably the most certain, the positive response of the Widal test I admit the overwhelming difficulty surrounding a positive diagnosis of typhoid fever in so young a subject from malarial, influenzial fever, ileocolitis, meningitis, or possible acute tuberculous, or auto infective fever From malarial fever we make the diagnosis by the absence of *plasmodium malarii*, and by the fact that I gave five grains of quinin per rectum for five days without any response in the temperature The temperature curve was too uniform for malarial infection From ileo colitis the diagnosis was easy, as the child was supported on mother's milk drawn from the breast and administered by a spoon While the case assumed a cerebral type, it was most evidently not one of meningitis No irregular respirations No constipation The pulse was not in keeping with the respiration No local paralysis No retracted abdomen The temperature was too high for meningitis The unequal and irregular class of symptoms which go to make up a severe case of influenza in the very young afford the most probable picture to which we may refer this assemblage of symptoms, yet the Widal test should incline us to regard it as a true, uncomplicated case of typhoid fever The urine in this case, while greatly reduced in quantity and containing an excess of urates and some oxalates, was free from indicanuria—a more positive evidence of auto-infection

I have selected the two cases of fever in young children, because they both stand on debatable ground, yet both possessing strong evidence of correct diagnosis The older child, with slow onset and general malaise, irregular type of fever followed by a most unusual form, gave strength to the assemblage of symptoms suggestive of true typhoid, yet, on closer scrutiny, they would negative this opinion, especially with a more conclusive test of Widal's reaction, ruling it out of this category

The second case, the young child of one year, with an assemblage of symptoms wholly unlike the unusual symptoms of typhoid, was undoubtedly a genuine one, not only by reason of exposure, but by the positive reaction test and the absence of indicanuria

The whole subject of auto-intoxication, as found in young subjects, is exceedingly fascinating as possessing such a kaleidoscope of passing, changing symptoms as to bewilder the investigator It has passed through many changes of meaning since its recognition Auto-intoxication through the intestinal canal consists of retention of the usual abnormal material in the bowels The result of this retention is decomposition, putrefaction and fermentation of the waste part of the food, giving us formic, buteric and lactic acid, and a generous amount of offensive gases pressing on the intestinal filaments of the pneumogastric and other nerves, giving rise to many local and general symptoms The decomposition of albuminous products gives rise to the formation of phenol, indol, skatal and tyrosin With knowledge of these many products of imperfect assimilation in the intestinal tube, a varied train of symptoms must necessarily arise, suggesting directly a disorder of the bowels themselves and reflexly of the respiratory system as seen in reflex bronchitis, nervous cough, local and general convulsions The circulation is positively disturbed, oftimes profoundly influenced, producing tachycardia, cold hands and feet, livid lips, blue eyelids, erythema fugax, and perspiring head and limbs The kidney may assume an effort to dislodge the intruder, as found in lithemic urine, excessive uric acid and indicanuria This long line of symptoms may be greatly enlarged, according to the personal equation of the investigator and the child's environments We possess one positive proof that they are actually associated with the poison retained in the intestinal tube, because the symptoms disappear when the fermenting masses are removed

That form of auto intoxication found in adults, characterized by depressed spirits, disgust for all exertion, retiring disposition bordering on melancholia—the pessimistic individual—has its parallel in the young child in feverishness, fretfulness, destructive ness, nameless crying, aversion, and unusual perversion of the childish state

Indicanuria I have found nearly always suggestive of auto intoxication in young children and precedes the more serious symptoms by many days This condition of the urine has not received the careful study it merits Constipation is not always associated with auto-intoxication, as we might first imagine

Oftimes the more fluid the intestinal movements are the more rapid may be the absorption of the poisonous material In these cases the urine is highly noxious, and a good example of this diarrheal form of auto-intoxication is seen in cholera However, in cholera the absorption of toxins seems to be continuous, while we may have frequent colliquative evacuations The convulsions in young children suffering from gastro-intestinal disturbances may be explained better in terms of auto-intoxication than by the usual reflex theory or the undeveloped cortex

---

SUBNORMAL TEMPERATURE IN TYPHOID FEVER

Presented to the Section on Diseases of Children at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10, 1898

BY H H FREUND, M D

PHILADELPHIA

The vagaries of the temperature history of typhoid fever are familiar to us all While the mass of recorded temperature shows a certain regularity extending over a period of nearly three weeks, in historic or average cases, yet our experience brings to our knowledge a series of cases at variance with the classic course These differences exist in cases gathered when happening in either childhood or adult life While in adult life we can with certainty prognose the febrile history in an average case, in childhood this is more difficult, as the vagaries of temperature are so elusive that many days may elapse before the true condition can be determined The degree of temperature is of different significance in childhood and adult life—what would be considered a dangerously high temperature in the adult would not carry the same import in the child Why this should be so, would seem to me to be due to the greater resistance of the adult against febrile disturbances due to septic influences

Why do our cases often present subnormal temperatures? is the subject upon which I would want the gentlemen to throw some light I have seen several instances of this phenomenon, but none in which this symptom was so marked and in which it persisted so long as in the case of a young boy whose history I will relate

The patient was 9 years old, healthy, well-proportioned, and had complained for several weeks before medical advice was sought When first seen, he had probably advanced well on to the second week of typhoid, with roseola well marked At the beginning of the third week, the temperature dropped as low as 96 4 degrees, axillary and *per orem* For eight days the temperature persistently remained about this degree During this time the patient was otherwise doing well, skin cool and dry, intellect good urination good, bowels opened each day presenting nothing unusual, no evidences of internal hemorrhage Patient felt well, did not complain of any unusual aberrations, finally on the eighth day, we were enabled to record a natural temperature This long-continuance was a source of great anxiety to all concerned, yet despite all our efforts to restore the normal condition, no means seem to have been of the least avail

---

An Encouragement —In the United States 70 000,000 gallons less of alcohol were consumed in 1896 than in 1888

OBSERVATIONS IN DIPHTHERIA

Presented to the Section on Diseases of Children at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10 1898

BY H D JEROWITZ, M D
KANSAS CITY MO

It is not the purpose of this paper to lecture upon diphtheria and its treatment before this assembly of eminent physicians nor to enter into any detailed bacteriologic study which would perhaps be only an incomplete reiteration of principles thoroughly known discovered and taught by some of the other members present, but merely to base my remarks upon conclusions drawn from an impartial observation covering an experience of seven years, which, as has been my good fortune, has been much larger than one would naturally expect for that short space of time As to conclusions, it must be remembered that experiences vary with different observers, depending 1, upon the virulence of the epidemic, and 2, upon the mode of treatment A third item may also be mentioned, as it plays an important rôle in deductions made in this article, and that is the susceptibility and resisting powers of certain classes or sects of people

From this it is evident that unless the observation includes all the different sects and all kinds of epidemics, statistics would not be reliable Such an extensive experience, however, could not be expected from a general practitioner in a town of 150,000 inhabitants, having no children's hospital or any other opportunity of studying the cases, except as they occur in private practice The observations include several hundred cases of "exudative" or "membranous" angina, having the diphtheria bacillus The majority of these cases were comparatively mild and some could not be distinguished from an ordinary sore throat with either a punctate or a coalescent exudation A certain number (about 8 per cent) were followed by paralysis and some had laryngeal involvement (about 4 per cent) For a long time I was reluctant to call these cases diphtheria, as they did not appear serious enough

It seems that the ancient diphtheria described in text books and the modern diphtheria, having as its principal diagnostic point the presence of the Klebs Loeffler bacillus without regard for the clinical appearance, are two different things The books describe diphtheria as a severe sickness with profound septic poisoning, a depressed heart and a rapid tendency to cardiac failure, the latter being the chief cause of death, and occurring often inside of twenty-four hours The patient is said to present an anemic appearance and the fever is not high The membrane upon which they dwell a good deal is said to be gray and *within* the mucous membrane, not a superficial exudation It is not detachable, as it is really the mucous membrane itself, whose only possible way of removal is sloughing off, leaving a raw ulcerated surface which has to heal The glands of the neck are enlarged, which is also considered a constant symptom The mortality is given all the way from 50 to 100 per cent, and some physicians even today believe that when a case recovers it was not diphtheria

The modern diphtheria of today is any sore throat, even without exudation, which will give a culture of the Klebs-Loeffler bacillus The child may apparently be well and play, there need be no cervical enlargement, no dirty membrane which is undetachable, the principal thing is the germ In some of these cases there is a decomposition going on in the throat with septic infection and usually a fatal result It is evidently the fact that formerly only these septic cases were considered diphtheria, hence, the great rate of mortality But now, when the diagnosis is made so much oftener, I find that diphtheria is not such a dreadful disease as generally supposed, and whose danger is like in measles, scarlet fever, etc, principally from the complications

The most important of these are involvement of the deeper respiratory passages, nephritis with uremic poisoning, septic infection, and sudden cardiac paralysis The clinical picture is about as follows Sudden onset with high fever, chilliness, and general malaise, sometimes vomiting and occasionally convulsions Very often the throat is not complained of and a diagnosis can easily be overlooked, until the condition becomes serious Such cases as these, it resulting fatally, unnecessarily increase the mortality rate, hence it should be the rule of every physician who has been called in to see a sick child to examine the throat, even though he be positive of its uselessness On examining the fauces we find a white or yellowish patch on one or both tonsils, extending sometimes to the posterior wall of the pharynx and uvula, and even further This exudation can in a great many cases be removed, but it will soon reappear If left alone it will disappear in from ten to fourteen days—sometimes longer It does not slough off, in some cases it simply loosens and is spit up, while in cases where it is more adherent it seems to become absorbed, getting thinner and thinner until it finally disappears, leaving a healthy mucous surface, which in some cases may appear slightly congested, but not raw

When the lower air passages become involved, unless the trouble begins there, the attack is usually sudden and entirely distinct from the pharynx It does not extend from the latter to the larynx, but *is a separate procees* It is recognized by the hoarse and croupy cough, and the stridulous respiration

Uremic symptoms occurred in about 5 per cent of the cases, and these would invariably have paralysis Albumin was rarely found, being absent in many cases having uremic symptoms The paralysis involved principally the muscles of the throat In three cases it affected the ciliary muscle of the eye, having the same effect as if a mydriatic had been employed In one case it involved the left arm, in one both lower extremities, in two the muscles of the back and the back of the neck, which resulted in a drooping of the head, in one beginning with the muscles of the throat, extending to the extremities, then to the muscles of the chest and finally the heart, and in still another, now under observation, the paralysis involves the sphincters of the bladder and anus and the muscles of the left hip and leg With the exception of the one fatal case and the one now under observation, the paralysis disappeared, varying in its course from one week to three months

The number of deaths was seven This is about 1¾ per cent A brief description of each would perhaps be of interest

Case 1 —Female child, age 3½ years Had been sick for a week before medical aid was received Pharynx, larynx and trachea involved Tracheotomy was advised but refused until the patient was almost exhausted It was then performed, but patient died next day from exhaustion No antitoxin used

Case 2 —Male child, age 3½ years Began slightly on tonsils, but child played on the street right along, and soon became croupy, and was so for three days before I was called Finding just a small speck of exudation on one tonsil, and having treated the other children of the family that week for a mild diphtheria, I warned the mother of the seriousness of the case, but she said the child always was croupy when ever he took cold, and disregarded the advice The next morning the condition became worse, the breathing very stridulous and difficult and the lips cyanotic After an unsuccessful attempt at intubation, tracheotomy was performed and the child at once improved The membrane involved the wound and twelve days afterward the child died at night from neglect by allowing the tube to get plugged up No antitoxin was used

Case 3 —Female child 3½ years old Took suddenly sick with laryngitis one day, and the next day the obstruction was so complete that the child was apparently dead, when intubation was attempted, but as it was not considered safe with this, tracheotomy was resorted to Then with artificial respiration and application of heat to the body, the child rallied after about five hours and was able to sit up and drink The following morning the child died of neglect, the inner tube having been laid on a table by the attendant and forgotten to be replaced, so that when the child was beginning to suffocate, the attendant in trying to remove the inner tube (which was not there) lost so much time by thinking it was caught in some way, that the child succumbed In this case no membrane was visible and no antitoxin was used

Cases 4 and 5 —These two cases were one male and one female, age 3½ years, who had septic infection and laryngeal involvement Antitoxin was used too late and shortly before death tracheotomy was performed, which relieved the dyspnea for an hour, when they succumbed to cardiac weakness dependent on the septicemia

Case 6 —Female child 3½ years old Had, together with the other children of the family, tonsillar diphtheria, which disappeared in about three or four days in all of them But in this one about three days afterward, fever developed, and a slight patch reappeared on the tonsils When the child cried there seemed to be a stridulous or sawing noise which led to an examination of the lungs There were subcrepitant râles showing that the lungs must have been involved There was no cough nor hoarseness The child was apparently well, and when asleep there was not the slightest noise with the respirations Only when the child cried could this peculiar sound be heard This child lived another week after this, dying from slow carbonic acid poisoning, as was noticed by the gradually increasing cyanotic appearance No antitoxin was used

Case 7 —This case was a tonsillar diphtheria of one side The membrane disappeared in five days by gradual absorption then came uremia and paralysis The urine was full of albumin, dropsy developed, and the paralysis increased until it involved almost the entire body Soon the albumin and dropsy disappeared, the paralysis became somewhat better, the child sat up, and in reaching for something, sudden death occurred This was about six weeks from the beginning of the illness No antitoxin had been used

In summing up these cases, No 1 might have been saved with antitoxin, if used early enough No 2 died of neglect, but antitoxin would have prevented the operation No 3 had no visible membrane, and died of neglect Nos 4 and 5 could not have been saved No 6 could have been saved with antitoxin if it had been used in the first attack No 7 might have been saved by antitoxin, but as the exudation was of short duration, and the general symptoms mild, it is a question

Thus, out of the seven fatal cases, only three could be really attributed to the disease This would make a mortality of three-fourths per cent

TREATMENT

As to the treatment, I only wish to mention a few points It is useless to detach the membrane for two reasons First, it quickly reappears, thus giving it new activity and prolonging the disease Second, by forcibly detaching, the surface is abraded, and septic infection easily follows I dare say that if you leave the membrane alone in all cases, you will have less septicemia and less deaths Gargles or sprays should be mild, antiseptic, and often When not practicable, antiseptics such as listerin, hydrogen peroxid, etc, can be administered internally Whisky for stimulation Plenty of water in all cases, and calomel when indicated, especially in uremia Iron I never employ, as by its astringent and cauterizing properties it can only interfere with natural drainage and healthy excretion With this treatment, the disease can not be cut short, nor does it prevent its extension For this we must employ antitoxin

ANTITOXIN

As to the use of this agent, I can give you my observations from an impartial standpoint The first thing noticed after using antitoxin is a reaction, an immediate effect, something that we do not observe after other remedies unless we give full doses It is therefore evident that the antitoxin is a powerful agent, and certainly produces some change in the system

The second thing noticed is that in every case where I administered antitoxin in the proper dose, the membrane disappeared inside of three days Without its use, while I have seen cases get well in the same length of time, yet the majority of cases lasted from ten to fourteen days Third, in all cases where I employed antitoxin in the beginning the larynx did not become involved, and uremia did not occur, while in cases treated without antitoxin the larynx became involved frequently, and uremia also followed Fourth, in cases where the membrane involves the larynx, trachea, and even the bronchial tubes, recovery followed when treated with antitoxin while the same class of cases before the use of antitoxin always died Fifth, neglected cases complicated with septicemia and laryngeal involvement, do not recover with any treatment Sixth, in severe cases of dyspnea, with occasional cyanosis, the use of antitoxin and emetics has obviated the necessity for tracheotomy Seventh measles as a complication is no bar to the use of antitoxin Eighth in laryngeal cases complicated with uremia or nephritis antitoxin was followed by favorable results, thus proving that uremia and nephritis are not necessarily contra-indications to the use of antitoxin Ninth, as paralysis was seen to follow only the cases of long duration, those in which antitoxin was administered early were not followed by paralysis Of those in which it was given on the second or third day it followed in about 8 per cent of the cases From this it follows that antitoxin does not prevent paralysis except indirectly by cutting short the disease Tenth, place of injection, behind scapula No abscess or other bad result followed

INTUBATION

This has been resorted to in extreme cases Some cases were rendered worse, and were at once followed by tracheotomy Some were only slightly improved, and in these the tube was removed and the patient carefully watched, so that tracheotomy could be performed immediately upon indication therefor, but the severe attacks of suffocation were only transient, and surgical intervention became unnecessary

TRACHEOTOMY

This was performed five times, all proving fatal Two of them died of neglect, two of them had profound septicemia at time of operation, and were only temporarily improved so far as respiration was concerned, and one was already exhausted from suffocation, owing to procrastination on the part of the parents The operation was always done without an anesthetic There were a great many other cases that seemed to indicate tracheotomy and looked as if they could not live more than an hour or two, yet they recovered without the operation Therefore I think that cases recovering from an early tracheotomy would have done so without it In cases dying from slow carbon dioxid poisoning from membranous bronchitis or membranous pneumonia, I did not perform tracheotomy, as it seemed to me useless

Let us summarize a few points

1 The majority of cases are mild, and affect only the tonsils and pharynx

2 The exudation lasts from one to two weeks There are exceptions to this

3 Removal of the membrane is useless, as by denuding the surface septic infection is promoted, and besides, the membrane soon reappears and remains longer than if it had not been meddled with

4 The involvement of the larynx is always sudden and comes as a new attack, and not by extension of the diphtheritic process

5 The larynx becomes involved in about 4 per cent of the cases

6 Every case complicated with uremia had post-diphtheritic paralysis

7 Laryngeal involvement is to be most dreaded between the ages of 3 and 5

8 Intubation and tracheotomy will become less and less necessary as the value of antitoxin is being recognized

9 Conclusions as to antitoxin have been given above

INDICATIONS FOR INTUBATION

Presented to the Section on Diseases of Children at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo June 7-10 1898

BY H M McCLANAHAN, M D

OMAHA, NEB

The conclusions deduced from a study of the symptoms of laryngeal diphtheria, as stated in this paper, are the result of personal observations at the bedside My sole object in presenting them to the distinguished members of this Section is to elicit their candid criticisms, that, profiting by their large experience, I may be the better qualified to decide when to act, when to defer and when to desist

When called into the presence of a little patient suffering from laryngeal diphtheria, the decision of the question whether to intubate or not is a very grave one, and we can only rightly measure our responsibility when we realize that a human life may be sacrificed by an erroneous decision Aside from the symptoms, our decision will be modified by two circumstances, namely the previous treatment and the environment of the patient Before the discovery of antitoxin, the majority of cases of laryngeal diphtheria became urgent enough to demand intubation for their relief Under the influence of this remedy 60 per cent recover without mechanical aid It will be apparent then that in a given case our decision will be modified by the fact whether antitoxin has been previously administered We may defer operation in a case already under the influence of this remedy, whereas in another case presenting identical symptoms we would feel warranted in intubating at once, because twelve to twenty-four hours must elapse before amelioration of symptoms can be expected In hospital practice, with a resident physician constantly at hand and competent to operate, surgical interference may be deferred for immediate urgent symptoms, knowing that the relief of the stenosis can be procured in a few moments In private practice, where a delay of hours might easily occur before the physician could return to the patient, greater caution is necessary My conclusions are deduced from cases in family practice, and it is from that standpoint that I wish to discuss the subject

Let us briefly note the symptoms that indicate the necessity for intubation:

The character of the respiration —Labored inspiration is a constant symptom in all varieties and degrees of laryngeal stenosis The importance of this symptom depends upon the amount of muscular effort expended in pumping air into the lungs There is no way of measuring this expenditure of vital force more certainly and accurately than by observing the extent of the epigastric recession with each inspiration Where there is noticed a deep depression, we may be certain that the patient is in a critical condition, and we have no assurance as to how long he may be able to continue this effort Intubation here meets two important indications More oxygen is received into the lungs, and violent muscular effort is suspended, increasing the vitality and saving the strength of the patient Labored expiration is an important symptom; to my mind, the most important evidence of a pseudo membrane in the larynx While this is usually associated with labored inspiration and other symptoms, the two are not always in proportion, for example, in one case each expiratory effort was prolonged and labored, with a pause at the end of the inspiratory act, but inspiration was comparatively easy, with but slight epigastric recession, yet this patient was both cyanotic and extremely restless Intubation restored the rhythm of the respiratory act with prompt relief of the cyanosis

The number of respirations per minute —This is important, as indicating the extent of involvement of the respiratory tract In laryngeal diphtheria my observation has been that the respirations are not greatly accelerated, whereas if there be involvement of the lesser tubes and air vesicles, we find both labored and rapid respirations This class of cases present the most unfavorable prognosis, not so much on account of the laryngeal stenosis as of the septic pneumonia complicating the case While in these cases intubation will relieve the labored respiratory act, it does not lessen the frequency of the respirations I believe, however, the operation is indicated, not only to relieve the stenosis, but to enable the child to cough more vigorously, and more effectually to clear out the lesser bronchial tubes In two cases where the symptoms were not extremely urgent there were attacks of dyspnea, due to spasm of the muscles of the larynx, presenting a typic picture of spasmodic croup Both became markedly cyanotic during the attack There was no evidence that this was due to particles of loosened membrane, and I am satisfied from the study of the cases that it was a spasmodic condition complicating the true croup This complication adds greatly to the suffering of the patient and the anxiety of the friends The history of such attacks, coming on at irregular intervals, in a case where the other symptoms are not extremely urgent in the interim, in my experience, demands intubation In the two cases of this type—while I do not affirm that they would have terminated fatally—I do say that, as the result of intubation, they recovered more comfortably

Extreme restlessness —This is an important symptom When a child is continually changing its position and tossing about from side to side, we may feel certain that it is in a dangerous condition While this symptom is usually associated with the other symptoms, especially that of epigastric recession, I have seen cases where this was by far the most prominent feature Indeed, in two cases, but for the restlessness, the patient would not have been thought in immediate danger I am satisfied this restlessness is due to a lack of oxygen, and is dangerous not only for this reason, but also because the patient rapidly wears itself out by its exertions When, therefore, extreme restlessness is a marked symptom, even if the other symptoms do not appear urgent, it demands intubation for its relief The relief given in these cases is usually very prompt

Cyanosis —When not due to a spasmodic condition or loosened membrane cyanosis is usually a late symptom, and a very serious one We sometimes notice this symptom where the others are not prominent, but as far as I have observed, it has been preceded by the other symptoms mentioned I am satisfied that many cases of this type are not cyanotic so much on account of the laryngeal stenosis as because of obstruction in the deeper portions of the respiratory tract, and I think this explains why it is that intubation often fails to give complete relief. The operation is indicated, however, to relieve the stenosis and to enable the child to cough and more effectually clear out the deeper portions

From this brief study I will draw the following conclusions The majority of cases recognized early are amenable to treatment by antitoxin A certain number, however, fail to respond to the remedy In these cases, if at the end of twenty-four hours a study of the symptoms leads us to the conclusion that the patient is not better, then intubation should be done In all cases presenting any one of the following symptoms prominently, namely deep epigastric recession with each inspiration, labored and prolonged expiration, extreme restlessness, spasmodic attacks coming on at intervals, or persistent cyanosis, then intubation should be performed I am satisfied that in our enthusiastic confidence in antitoxin, we often expect too much from the remedy, and that in cases seen late it would be wise to intubate and administer this remedy rather than give the remedy and wait for its effect Antitoxin and intubation are in no way antagonistic Intubation is the complement of antitoxin, to be used only where indicated, and when indicated it is generally a life-saving operation

---

INTUBATIONS FOR DIPHTHERITIC CROUP

A REPORT OF THIRTY-EIGHT CONSECUTIVE CASES WITH THIRTY-SIX RECOVERIES ALL TREATED WITH ANTITOXIN

Presented to the Section on Diseases of Children at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY F E WAXHAM, M D
Professor of Diseases of the Chest and Laryngology Chicago Clinical School
CHICAGO ILL

Desiring to add my testimony to that of many regarding the value of one of the gr
of the century, I beg l to p

cases on record These cases were no less severe nor less dangerous than those operated upon before the days of antitoxin, and the great reduction in mortality can not be attributed to a milder type of the disease

June 30, 1895, through the courtesy of Dr L T Durbin, I was called to operate upon a boy of 3 years The tube was worn six days, being coughed out once, but returning dyspnea required its reintroduction Antitoxin used, bacteriologic examination positive, recovery slow, but complete

Sept 2, 1895 Dr Wm P Munn called upon me to intubate a child 2½ years old The patient was nearly dead from asphyxation Antitoxin given, tube ejected several times from exfoliation of membrane below the tube, bacteriologic examination positive, uneventful recovery

Oct 6, 1895, I was called by Dr A M Bucknum The patient was 2½ years old Antitoxin given, child greatly exhausted from difficult breathing, examination positive, good recovery, tube was worn five days

Oct 16, 1895 Dr J W Hawk called me to operate upon a boy 3 years old Patient greatly exhausted, removed tube on third day, but it became necessary to reintroduce it, The tube was permanently removed on the ninth day, examination positive, antitoxin used, good recovery

Oct 23, 1895 Courtesy of Dr David Thompson Patient 2 years old, very unfavorable case, nasal cavities, pharynx and larynx involved and the child nearly dead from asphyxia Antitoxin given and intubation performed, examination positive, tube worn five days, perfect recovery

Oct 23, 1895 Courtesy of Dr C B Richmond Patient 3 years old, pharyngeal and laryngeal diphtheria Antitoxin given, intubation performed, examination positive, tube worn five days; recovery

Aug 6, 1896 Courtesy of Dr Hugo Mager Examination positive, antitoxin, recovery, tube worn four days, age 6 years

Sept 13, 1896 Courtesy of Dr P V Carlin Examination positive, antitoxin, recovery, tube worn four days, age 16 months

Nov 8, 1896 Courtesy of Dr Charles Jaeger Examination positive, antitoxin, recovery, tube worn five days, age 4 years

Dec 2, 1896 Courtesy of Dr Catherine Hayden Examination positive, antitoxin, recovery, tube worn five days, age 2½ years

Dec 31, 1896 Courtesy of Dr George Packard Antitoxin, recovery, wore tube four days, age 3 years

Jan 12, 1897 Courtesy of Dr L E Lemen The patient had been sick with croup for three days before the doctor was called, membrane had already invaded the bronchi Intubation done at once and antitoxin given, examination positive Tracheotomy became necessary twenty four hours after intubation on account of membrane in lower trachea and larger bronchi Death occurred within twelve hours, from bronchial obstruction Age 4 years In the light of our present knowledge we should have given antitoxin in double the strength and repeated it more frequently

Jan 22, 1897 Courtesy of Dr Herrick Examination positive, antitoxin, recovery, tube worn two days, age 3 years

April 7, 1897 Courtesy of Dr P V Carlin Positive, antitoxin, recovery, age 2½ years, tube worn four days

Aug 14, 1897 Courtesy of Dr F E Warren Positive, antitoxin, recovery, age 4 years, tube worn five days

Sept 30, 1897 Courtesy of Dr H L Taylor Positive, antitoxin, recovery, age 4 years, tube worn five days

Oct 16, 1897 Courtesy of Dr D R Lucy Positive, antitoxin, recovery, age 2 years, wore tube six days

Oct 31, 1897 Courtesy of Dr P V Carlin Positive, antitoxin, death occurred from broncho pneumonia thirty six hours after the operation Age 16 months, surroundings very unfavorable people living in a shack of two rooms

Oct 31, 1897 Courtesy of Dr Von der Smith Positive antitoxin, recovery, expelled tube on the third day, age 1 years

Nov 7, 1897 Courtesy of Dr Leavitt Positive, antitoxin, recovery, wore tube five days, age 3 years

Nov 23, 1897 Courtesy of Drs H B Whitney and H C Snitcher Positive, antitoxin recovery, wore tube five days, ars

97 of vid Thompson Positive, nd a half days, age 1

ington and Munn

Positive, antitoxin, recovery, wore tube seven days, age 5 years

Dec 13, 1897 Courtesy of Dr A K Worthington Positive, antitoxin, recovery, age 2½ years, wore tube six days

Dec 14, 1897 Courtesy of Dr H C Smitcher Positive, antitoxin, recovery, age 13 months, wore tube nine days This was the fourth case of diphtheria in the family, and the second one operated upon

Dec 21, 1897 Courtesy of Dr Frank Dulin Positive, antitoxin, recovery, age 6 years, wore tube five days

Dec 30, 1897 Courtesy of Dr C P Perry Positive, antitoxin, recovery, age 2 years, expelled tube on fifth day

Jan 1, 1898 Courtesy of Drs McLaughlin and Weaver Positive, antitoxin, recovery, expelled tube on fourth day, age 6 years

Jan 15, 1898 Courtesy of Dr J S Neva Positive, antitoxin, recovery, age 6 years, tube worn five days

Jan 31, 1898 Courtesy of Dr P V Carlin Positive, antitoxin, recovery, age 2½ years Tube removed on fifth day

Feb 3, 1898 Courtesy of Dr P V Carlin Positive, antitoxin, recovery, age 6 years, removed tube on fourth day

Feb 15, 1898 Courtesy of Dr P V Carlin Positive, antitoxin, recovery, age 8 years, removed tube on fourth day

Feb 20, 1898 Courtesy of Dr D R Lucy Positive, antitoxin, recovery, age 2 years, removed tube on sixth day

Mar 3, 1898 Courtesy of Dr I B Perkins Age 17 months, positive, antitoxin, five doses, each 1000 units, recovery, removed tube on fifth day

Apr 27, 1898 Courtesy of Dr T J Carlin Positive, antitoxin, recovery, removed tube on fifth day, age 2 years

May 11, 1898 Courtesy of Drs Ellsner and Gorsuch Positive, antitoxin, recovery, removed tube on fifth day, age 6 years

May 12, 1898 Courtesies of Drs Warren and Worthington Positive, recovery, removed tube on sixth day, age 2 years

May 24, 1898 Courtesy of Dr P V Carlin Positive, antitoxin, recovery, tube ejected two days after introduction, age 20 months

In this connection I would allude to an adult, 40 years of age, with diphtheritic croup, to whom I was called in consultation with Dr W E Shotwell The patient expelled a membranous cast of the trachea and recovered under repeated doses of antitoxin without an operation Recovery was formerly so very rare in the adult, that I believe this case is worth recording I should also call attention to a case to which I was called by Dr P V Carlin, March 1, 1898, and which has been excluded from this report, as the patient was moribund and died during the operation, and could not be resuscitated, although tracheotomy was also performed This is the only case that has been excluded

To recapitulate of the thirty eight cases operated upon, five were under 2 years of age with four recoveries, or 80 per cent, eleven were 2 years old, with eleven recoveries, or 100 per cent, six were 3 years old, with six recoveries, or 100 per cent, seven were 4 years old, with six recoveries, or 85 7 per cent, two were 5 years old, with two recoveries, or 100 per cent, six were 6 years old, with six recoveries, or 100 per cent, and one 8 years old, with one recovery, or 100 per cent, total, thirty-eight cases, with thirty-six recoveries, or 94 7 per cent—a mortality of only 5 3 per cent in a class of cases that formerly was dreaded above all others

A few years since it was my experience, out of several hundreds of operations to have saved 35 per cent Why this great reduction in mortality from 65 per cent to 5 3 per cent? There is but one answer It has been due to the use of antitoxin If my experience stood alone the conclusion might well be doubted, but inasmuch as the great reduction in mortality has been noted by all operators, it must be conceded to be correct In former years patients died, in the great majority of cases, after intubation or tracheotomy, from the extension of the diphtheritic exudate into the bronchi At present this rarely occurs I am fully convinced that when antitoxin is properly and energetically employed in full doses and repeated, the disease is at once cut short and no further progress occurs I am also convinced that if a patient dies after intubation from bronchial obstruction due to the presence of diphtheritic exudation, the remedy has either been used late, the extension having taken place before its administration, or it has been used with a hesitating hand and in insufficient dosage, or the preparation has been of uncertain strength When a child is taken ill with diphtheritic or membranous croup—which I consider identical—the danger is so great that hesitation in the heroic use of antitoxin is almost criminal I certainly should advise a full dose of 2000 units even for a child, and half the strength for infants, repeating the dose in twelve or sixteen hours In one of the cases reported, four doses of 1000 units were given an infant 13 months old, and in another 17 months old, five doses of 1000 units without any injurious effect

Even at this late day we occasionally meet with those who still cling to former methods of treatment, hoping to carry their patients through without subjecting them to the dangers (?) of antitoxin, and who are apparently afraid of the remedy and hesitate about repeating the dosage I would again and again repeat and emphasize the fact that antitoxin *must* be given early It *must* be given in full doses and repeated once, twice or thrice, if necessary My confidence in antitoxin is so great that I sincerely believe that with intubation, aided by the proper and free use of this remedy, death from diphtheritic croup should rarely occur

---

DIPHTHERIA AS VIEWED BY THE GENERAL PRACTITIONER DURING THE LAST YEAR

Presented to the Section on Diseases of Children, at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY ALEX McALISTER, M D

CAMDEN, N J

It is not my aim to present a learned dissertation either on the pathology or scientific treatment of diphtheria These subjects have been before the profession so constantly during the last three years that such a paper would prove only an intrusion upon your valuable time What I wish to do is simply to make a few practical observations that must be patent to every general practitioner Until recently diphtheria ranked as the gravest of the anginas and the most dreaded of the acute febrile affections This applies with especial emphasis to the laryngeal types, formerly largely regarded as a distinct disease, but now generally recognized as identical with diphtheria of the larynx and properly treated with heroic doses of antitoxin Yet the nasal and naso-pharyngeal types with their preponderance of constitutional manifestations and former frightful mortality were scarcely less dreaded both by the physician and parent

Recent advances in diagnosis and treatment, it seems to me, have left scarlet fever at the head of the anginas and typhoid at the head of the acute fevers in point of morbid possibilities Even the progress which has been made in diagnosis is to be credited to antitoxin, it being due to the new impulses contributed by serum therapy In the American Pediatric Society's report on the collective investigations of the antitoxin treatment of laryngeal diphtheria in private practice, this advance is admirably noted in the following words "In the early days of intubation it was customary to speak of the percentage of recoveries, and 24 to 27 per cent were considered good result In the last report the recoveries had crept up so high in the one hundred cases that it seemed more natural to speak of the percentage of mortality", and again, in speaking of O'Dwyer's personal experience prior to the introduction of antitoxin, in nearly five hundred operative cases of laryngeal diphtheria in which the mortality rate was 72 44 per cent "When he had reached the seventieth case on the fifth hundred something occurred which carried the phraseology up over the divide At this point in history, antitoxin arrived and interrupted forever the old series In his next fifty-nine cases the mortality was 23 7 per cent'

Recognizing that the past year was doubtless exceptional in many a section of our country for the small number of cases of diphtheria which appeared, it may nevertheless be observed that, incidentally with the more general introduction of serum therapy, we have a decrease in the number of cases as well as in the severity and popular dread of the disease and the rate of mortality This wholesome change is due to an ever broadening and deepening conception of both diphtheria and its *biologic antidote*, antitoxin

The resort to immunizing injections to prevent the spread of diphtheria to other members of the family where a case or two has appeared, is not so largely practiced as the value of the measure demands, but is rapidly gaining in popular favor But aside from any resort to this measure, it is evident that serum therapy has exerted a most potent influence in restricting the number of cases While it is always within the range of possibility for the most malignant case to follow the mildest case, yet the proneness to spread the infection is always greater in severe cases Admitting this, it is clear that whatever checks malignancy also controls the tendency to spread and materially restricts the number of cases that would otherwise occur This beneficent influence can never be adequately estimated, although it is very considerable One of the most encouraging experiences of many a general practitioner who has adopted the serum treatment of diphtheria, is that he now only occasionally meets more than the initial case or cases in a family Many of the latter class even assert that they never even meet the exceptional new infection

In view of all these facts, it would seem that the attitude of the general practitioner toward the serum treatment is a more seasonable subject for discussion than the merits of antitoxin In the investion of this most interesting subject the initiative was doubtless taken by Dr George L Cole of Los Angeles, Cal, who made a study of the question in his own State and reported, recently, in an admirable paper entitled "Sero therapy,' before his State Medical Society In reponse to a circular letter addressed to about three hundred physicians he received replies from 156 Of this number, only four expressed themselves as antagonistic to serum treatment, but none of these had personally tried the remedy nor had a desire to do so With the opportunity to compare the clinical notes of hundreds of physicians who have each treated many cases in private and hospital practice, of thousands of others who have less numbers, and with the unequivocal results of great collective investigations conducted both at home and abroad, it would seem that even the most obscure general practitioner is no longer justifiable in refusing to give his diphtheria patients the full benefit of the more humane and successful serum treatment According to my personal observations, this effect is rapidly being attained Physicians who were once loud in their opposition are now warm advocates, or in preference to the humiliation of a public retraction, have become secret users of antitoxin

Speaking of the product, as now freely available to every physician, it is to be observed that marvelous progress has been achieved I was one of the first in the East outside of our large cities to employ the remedy That was before antitoxin was prepared in Philadelphia for commercial or other purposes The article was then difficult to procure and very expensive The quantity of serum necessary to inject in order to secure what was then regarded a full curative dose was inordinate, being upward of one fluid ounce The syringe which I then employed has long since been laid aside as suggestive rather of minor rectal surgery The improvements which made it possible to inject much larger doses in very much smaller quantities of serum, that is to say, which gave us concentrated serums, are without parallel elsewhere in the pharmaceutic sciences

One year ago the most concentrated product in the market contained 500 immunizing units to each cubic centimeter of serum, but at present serums are available of 1000 and even 2000 units per cubic centimeter The latter, it seems to me, have reached a degree of concentration which is no longer advantageous or even practical A serum which contains nearly 150 immunizing units to each minim of the serum, or even half this strength, is relatively difficult to handle, owing to the small bulk and the unavoidable source of loss while it remains a question whether such high concentrations possess any special therapeutic advantages at all It seems to me, and in this I voice the sentiment of the general practitioners with whom it is my pleasure to exchange views from time to time, that a product permitting the administration of 1000 units of antitoxin in from 2 to 4 centimeters, i e, from one-half to one fluid dram of serum, if well ripened and conveniently bottled, is the ideal antitoxin from every point of view It is conceded that the more concentrated the product is the more readily deterioration takes place, so that the higher strengths are relatively unreliable after one to four months This in itself is a considerable disadvantage to the general practitioner, who, more often than any other class of physicians finds it indispensable to keep an available quantity of a strictly reliable product constantly upon his shelves To him there are a score of elements that enter into a particular antitoxic serum of vastly more importance than higher degrees of concentration, per se, however commendable as an achievement in its preparation the latter may be Chief among these elements I would name a high unit value, seasoning of the serum, a definite system of standardizing, convenient and sufficiently strong bottles and uniform potency

DISCUSSION OF DIPHTHERIA

Dr **Louis Fischer**, New York City—In the paper of Dr Engleman this morning I was interested in hearing that her results with the mixture of the antitoxin with anti strepto coccus serum were good I was very much interested recently to hear from some gentlemen discussing the subject, that they endorsed the view I maintained, namely, that antistreptococcus serum today can not be classed as a remedy to be used My experience dates back but two years, when I had the pleasure of seeing a series of cases under Dr Baginsky of Berlin We did not find it of value In one case, in which the antistreptococcus serum was used, the bad effects were due to its use Today we have not a streptococcus antitoxin, but only an antistreptococcus serum, which is not equally of value in all cases While doing good in erysipelas, it does not do good in cases of scarlet fever, although we have proven that the streptococcus is the etiologic factor in scarlet fever Therefore, I wish to reiterate what I said in New York, that I believe the time has not come when we may say that we are permitted to use the antistrepticoccus serum in the same sense that we use the antitoxin in diphtheria I would be pleased to hear if the various authors who have read today will state whether they have used this with the antitoxin, and their success

Dr Engleman stated that she fully believed the etiology to be still in a confused state Mr Chairman, I can only tell you of a very interesting case of a child who had an affection of the throat and showed the Klebs Loffler bacillus A child brought into the hospital for the relief of a phimosis, was operated upon and some of the smegma inoculated in a test tube When placed under the microscope beside a culture obtained from a case of diphtheria, a friend of mine, who is a bacteriologist, was absolutely unable to differentiate them When in Berlin I saw the streptococcus and staphylococcus in a great many cases While the accepted theory is that the Klebs Loffler bacillus is the sole cause of diphtheria, and that it can produce diphtheria, I think there is still room for improvement in the study of the etiology of diphtheria I learned from another bacteriologist, who said he knew of the bacillus of smegma, that is similar to the diphtheria bacillus I need only say a word of the pseudo diphtheria bacillus which is frequently present under normal conditions

Passing to Dr Jerowitz' paper, the gentleman referred to the fact that he does not use iron I was rather surprised to hear that statement, because I regard iron as one of the most important drugs in the treatment of diphtheria While the accepted conclusions in regard to antitoxin are so positive, I believe iron still holds its own as a remedy in diphtheria The treatment of diphtheria was in such a condition of chaos four or five years ago, in regard to this antitoxin question, that I believe we are to be congratulated on the progress made in this line, and I believe it is due largely to some men who have gone throughout the country and advocated the use of antitoxin Largely it is due to such work as that of Dr Rosenthal I will state, however, that I do not use antitoxin in every case It was only about two months ago that Dr Garrigues telephoned me to bring enough antitoxin for four cases But I found only some little spots, which by a little gargling got well I know another case in which by using a little wash the child recovered I do not use the antitoxin unless there is no improvement in twelve hours However, if I am called to a case in which a whole tonsil or the palate is involved or when there is stenosis, I would regard it as criminal not to use antitoxin I never give under two thousand units of antitoxin in any case

The paper of Dr Waxham is a valuable contribution The statistics are such that it would be a crime not to use antitoxin where there is laryngeal involvement The Doctor has shown the old tubes of O'Dwyer We have had the rubber tubes introduced, I believe I showed some of the tubes last year at the meeting of this Section in Philadelphia, and we have been using them since The lime salts do not deposit on them, which is of value especially in the cases where we must use the tubes for a long time In the case of a child I intubated on February 20, I am confident if I had used a metal tube I would have had to use a series of tubes by this time, but the rubber does not permit the deposit of lime salts on the surface Dr O'Dwyer's new sets have also these new tubes and they are made according to his own directions The tubes I use are made corrugated, because I find them so slippery that they are coughed out if we do not have them corrugated The gag of Dr Waxham I have used and I believe it is an excellent gag I should like to ask Dr Waxham how he treats his prolonged cases of stenosis Some cases were reported by Dr O'Dwyer at the last meeting of the Pediatric Society I refer to the class of cases where you have intubated and left the tube in for a week or ten days, removed the tube and have stenosis, and must they have prolonged intubation? I have mentioned a case where the child has worn the tube over three months I have tried tracheotomy in several of those cases and I have found that each and every one of them has died

Dr Ross ENGLEMAN, Chicago, in closing —I have nothing to say, except to emphasize the subject of polymorphism of the Loffler bacillus As the Doctor says, I think the subject is still in an experimental state I do not think we can say certain symptoms refer to the staphylococcus or streptococcus or Loffler bacillus infection, because of this polymorphism, and we often do not get anything except a mixed infection In my series of cases I did not use the antistreptococcus serum in sufficient doses, so I would not express an opinion as to its use in these cases As to the question of the prolonged intubation, I am very glad to hear from Dr Fisher of the use of the rubber tubes I have had a few cases that were very troublesome and shortly after I had those cases I read O'Dwyer's article, I think in the July number of the *Archives of Pediatrics*, in which he referred to the use of alum and paraffin, which seemed very ingenious and with which he said he cured his ulcers in a short time where the tube had been worn three months or longer

Dr JAQUES, Chicago —I had charge of the South Side Dispensary in Chicago at the time Dr Waxham was beginning his career as an intubator and I have called him out, in the most bitter and disagreeable weather, and he never has failed to respond to perform intubation In nine out of ten of those cases death followed When I recall the experience he went through I am glad no such experience will be possible for the next generation We should have in mind always the fact that it takes two things to make a case of diphtheria First, the predisposition to the disease, second, the presence of the germs I have frequently obtained cultures of the Klebs Loffler bacillus from my mouth, although I have never had diphtheria in my life In any individual not susceptible to diphtheria, there is, through the action of the cells, an antitoxin produced which protects the individual from the action of the germs When the individual loses this condition of resistance or it falls below a certain standard and the Klebs Loffler bacillus is introduced on the membrane, Klebs Loffler diphtheria will follow and will progress according to the susceptibility of the individual Unless you have the clinical symptoms following the finding of the germ, you do not have diphtheria Dr Waxham, in his paper, stated that he always gave at least two thousand units to a child and more to an adult If you will pardon me for a moment, I wish to illustrate the stand I have taken, that the younger the child the larger the dose of antitoxin should be, not in the amount of serum but in units We understand that the growth of the bacilli produces the ptomains In the experiments we estimate the amount of toxin which kills the animal by the size of the animal, and the smaller the animal the smaller the amount of toxin required to produce the animal's death The growth of bacilli here is as large in the infant as in the adult, and therefore a larger amount of antitoxin is required I use three or four thousand units in infants I want you to beware of the concentrated antitoxin A drop will stay in the syringe, a drop will be lost, probably, in seeing that you do not inject any air "I prefer the antitoxin of average concentration, say 5 cc to three or four thousand units One of the gentlemen who read a paper said he did not think antitoxin is a preventive of paralysis I do think the gentleman has carefully considered that statement You might as well say that water does not prevent the spread of fire Antitoxin does prevent paralysis The toxin produced by the Klebs Loffler bacillus causes necrosis, and when that ptomain accumulates to a sufficient amount to produce destruction of the corpuscles of the blood, the kidney tubules and the destruction of the vital centers, the patient will die So if you give your antitoxin it must be given before this destruction occurs and then you will prevent paralysis

Question —I would like to know how long they quarantine patients to prevent the spread of the disease

Dr JAQUES—In the Health Department of Chicago we do not placard any house unless the Klebs Loffler bacillus is found in the case and the diagnosis is made by one of the inspectors in the health department We have not followed the quarantine very carefully for the reason we work there in harmony with the physicians We are simply the assistants of the physician We say to the doctor, you go to your patient, take with you a little culture material, give it to us after inoculation and it will be returned to you as your private property The patients do not know in one fifth of the cases that the health department had anything to do with the case The physician is responsible for the spread of the infection, and he looks after it then very much better then the health department could do As a result our diphtheria statistics, as perhaps you know, have been remarkably low, being in the charity cases only 6 7, when formerly they were nearly 40

Question—How long do you keep the house placarded?

Dr JAQUES—We leave that to the discretion of the Doctor Often it does not stay on the house over an hour and often it remains on the house for a long time The patient is at once isolated, and if the patient is isolated and put in the care of a trained nurse, the individuals in the house are in no more danger than an individual in an ordinary street car If the physician desires to take the responsibility of the case, the placard need not go on the house at all Every doctor knows that when he calls on the health department he will not be interferred with in any way If the patient is so poor that antitoxin can not be bought, it will be furnished them by the health department without cost

Question—I would like to ask the physician from Chicago, if when he found the Klebs Loffler bacillus in his throat, and thought he was not subject to diphtheria, did he not think he was a menace to other persons, who were debilitated?

Dr JAQUES—I think the only time I would be a menace would be when kissing, and I am not subject to that habit When I found this bacillus in my throat, I was very careful to take means, by gargling, to keep my throat from being a subject of infection I have gone from a case of intubation to a case of confinement and performed version and do not know that I ever transmitted diphtheria There is a great mistake in the belief among the general public as to the contractibility of the disease and the danger of physicians If they are clean, there is very little danger of contagion Contagion is spread only by contact and not at all through the air

Question—Do you ever fumigate the premises after a case of diphtheria?

Dr JAQUES—We have spent several thousand dollars in the last year in the practical methods of fumigation, and we have found formaldehyde gas one of the most practical methods It is clean, leaves no odor and is one of the simplest and best methods We simply take formalin, or the 40 per cent. solution of formaldehyde gas, add four parts of water, stop up the cracks in the room, extend a sheet across the room and throw the solution on the sheet. We then get out of the room as quickly as possible The disinfection is perfect We place tubes, wrapped in flannel, in various places in the room and if any of them grow, the disinfection is repeated This does away with the use of sulphur and we find it by far the best method of disinfection

Dr AGNEW, Philadelphia—I think Chicago does better than Philadelphia In the first place, we have a hard and fast law that all cases have to be placarded When the culture is made the house is placarded and the placard is removed when disinfection is attended to I believe one of the causes of spread of the disease is the non report of cases of diphtheria, due to the fact that the placard interferes with people's business I think, myself, there ought to be discrimination and where the physician in charge is willing to assume the responsibility of isolation, the placard should not be on But the act of 1895 states that a placard shall be put on, and the Board of Health of Philadelphia, who have the discretion in this, have insisted on this placard being put on every house One of our most distinguished physicians in Philadelphia unfortunately had a case in his house, that I am satisfied everything was done to isolate, but in that case the placard was put on his house I believe cases of diphtheria can be so taken care of that the risk to other people will be reduced to the minimum, probably reduced to nothing It would be interesting to know whether in Chicago they use force to remove patients, where the doctor does not assume control of the case We have to deal with a population in my city where no isolation is used and we are allowed to send a force in and take the patient out You will all admit that under such conditions a case taken to our municipal hospital removes the center of contagion There is no question, when such a case is removed, that a benefit is conferred upon the city I know, myself, of a case which was not reported, that was visited by children invited from a kindergarten and several lives were lost and several children were sick for a long time I believe at least a hundred cases were kept out from the epidemic traced to this case The case was not reported and the doctor was brought into court and fined $5 for I don't know how many lives and how many cases of diphtheria

Dr W H SEIBERT, Pennsylvania—We have had the pathology, symptomatology, treatment, preventive measures, and even down to the police regulations, but one point has not been mentioned I refer to diphtheria occurring in regions not accessible to view, as in the alimentary canal or possibly in the posterior nares, where, however, it might be seen by proper instruments, and in other regions The Doctor has stated that he has gone from intubation cases to obstetric cases without danger Recently, I had some experience where a consultant, who had been treating malignant cases of diphtheria, was called to help in a case I asked him to examine the case, which he did He did not speak of his diphtheria case until the after course of our case of *obstetrics* There were peculiar symptoms appeared In fact, there were the general symptoms of diphtheria, but there were no symptoms of diphtheria about the throat The main symptom was complete anorexia, absolute repugnance of food That has not been referred to but is usually understood On examining everywhere, carefully, I could find *nothing to* indicate diphtheria until with the speculum I examined the vagina *On* the fifth or sixth day we found a diphtheritic patch inside of the vagina, which was nearly an inch in diameter The case occurred before the introduction of antitoxin, and the patient went on and died from diphtheria A few years ago, J Lewis Smith reported a case which died *from* what he had treated for some time for typhoid fever, but before death the patient passed a complete cast of the intestine, which *proved to be* diphtheritic on examination

Dr WELCH of Philadelphia [illegible] I fin[illegible] in t[illegible] enemy's camp That is to [illegible] no [illegible] have seen diphtheria, having had charge of a hospital where infectious diseases are constantly treated, for the past twenty eight years, and during the past six or eight years we have been receiving large numbers of cases of diphtheria, along with scarlet fever and some few of the other infectious diseases The death rate in our hospital before the days of antitoxin was never anything like as high as has been stated here by some of the speakers today Our death rate before antitoxin was from 28 per cent to 30 per cent, or along there somewhere as near as I can recollect now And, gentlemen, it remains there today We have not reduced the death rate whatever It is true in 1894 the death rate was higher than ever, it was high all over the world That is known by all who followed the literature of the period The death rate in our hospital was about 30 or 33 per cent It was about the same in the Willard Parker Hospital of New York, and in the Metropolitan Hospital However, in some of the hospitals the death rate has been very high, as high as stated here today After antitoxin came to our notice in 1894, we did our best to procure this agent, that our patients might have the benefit of it We succeeded in the fall of that year and were able to give it to only sixteen cases, I think, in the latter part of 1894 We watched those cases with a great deal of interest Their temperatures were taken every hour or two, notes made every little while, and we had complete histories reported of the first five cases They were pretty nearly the first cases in which antitoxin was used in Philadelphia Dr Fischer, who is present, knows something of those five cases, two of them died

We continued, and that year used antitoxin in about sixteen cases, but it was not lower than the usual death rate In 1895 it was not so difficult to procure antitoxin The preparation of the antitoxin we used then was Behring's number two It was not, of course, as easily and readily obtained in as large quantities as at present, it was high, and we economized its use as much as possible I attempted to select the cases which I thought most favorable to the action of the antitoxin Everybody who had written on the subject said antitoxin was useful only when used in the early stages of diphtheria I selected those that were from the first to the fourth day of the disease, well marked clinical casses, some of them very severe and others not so severe, but every one of them well marked and in every one of them the Loffler bacillus was present on culture Those which did not receive antitoxin were, first, exceedingly mild cases, which I believed would recover without any remedy, second, cases advanced beyond the fourth day, and third, malignant or moribund cases It was thought they would serve no fair test of the remedy At the end of the year in counting up the cases there were about three hundred received antitoxin and over five hundred did not receive it The cases were not analogous and could not be compared But the death rate among those from the first to the fourth day who received antitoxin was about 28 14 per cent, while among the other class it was 25 per cent and a fraction, I think very nearly 26 per cent Now, I do not say that these series of cases should be compared, for they are entirely different, as I have told you I was surprised that the death rate should be so high In closely watching these cases after the administration of antitoxin, particularly my early cases, no one can well imagine my disappointment I really expected antitoxin to do all they claimed for it It did not Now, I have no prejudice, I wish antitoxin would do what they have said it would I thought I would get out of writing so many death certificates, but the patients have died just the same In watching the cases I could not see such a beneficial effect from it Sometimes we thought we did see the change in the exudate, that it assumed a more fat-like appearance and peeled off more readily But right along the side of them you could pick out the same number that did not receive the antitoxin but behaved in the same way I can not say that I have observed that the exudate disappears more quickly after the use of antitoxin If there is any difference it is not striking There are some cases where it peels off quickly, there are other cases where it remains for a long time, there are cases where it disappears and reappears, and there are cases where it travels even down into the larynx A good deal was said about the temperature Temperature in diphtheria counts for very little, except in the worst cases it is usually low In the vast majority of cases the temperature is high at first, but in a short time it sinks to normal, or nearly so, and in bad cases to below normal In the hospital you will see very few cases with high temperature, except in cases of broncho pneumonia This is very common and many of the intubated laryngeal cases die from it Many of them die late, some die two or three weeks after they have been admitted into the hospital A week or two after the tube has been removed bronchial pneumonia develops and they die We all know the theory by which antitoxin acts, the theory of immunity, that in a person who has suffered from some one of the infectious diseases there is an antitoxin produced in the blood and that this antitoxin protects them against future attacks This is a beautiful theory, but it seems to me it is not proved No one has ever discovered antitoxin, described it or told us anything about it Now, what does nature show us? What do we find in practice in our daily observations? Take, for instance, a woman who is rendered immune to smallpox, which is a common disease and one of the most contagious and infectious diseases we have Take a person immune to smallpox, either by reason of vaccination or previous attack, say the individual is a female and there is an antitoxin developed in her blood which protects her That woman becomes pregnant and gives birth to a child That child, it seems to me, should receive immunity from its mother Yet that child, from the time of its birth, is susceptible to the disease The woman may not be affected by a disease to which she is immune, but the fetus in utero may be susceptible If it will protect her, why will it not protect the fetus in utero?

Dr R B **Gilbert**, Louisville —My experience has been so much in common with that of Dr Fischer that I regret the last speaker I have treated cases without the serum and have had a mortality of 65 or 70 per cent, and with the antitoxin I have had a mortality of from 7 to 10 per cent The cases were in the same epidemic with the same environment and proper attention I believe antitoxin should be used early and in the quantities stated by Dr Fischer In a case of laryngeal diphtheria in a child under two years of age it is scarcely worth while to use the serum late But if we see such a case early we might have quite a success with it My experience has been only in general practice through a number of epidemics and not in hospital practice I have succeeded in saving a large number of cases, which I know would have died had I not used the serum

Dr **Simmons** of Nebraska —I am sure antitoxin is as nearly a specific for diphtheria as any medicine we have for any other disease I do not believe quinin is as much a specific for malaria as antitoxin is for diphtheria In the early years of my practice I ran into a lot of diphtheria, in which all the physicians lost nearly all of their cases Nothing could save them Twice in my medical experience since then, once about eight years ago and once about six years ago, I had the same class of cases During the intervening periods we had a class of cases that were mild I have been anxiously waiting with a good deal of fear for a chance to try antitoxin in the old type of diphtheria About two months ago I had such a chance Until then I was ready to say that I thought what I had read was all right, for I had used it for some years, but during the last two months I have had such experience that I do not care what statistics are brought up nor what anybody else may say, I know I have saved cases with antitoxin I will just relate two instances in two families One was a family of nine children They were poor people and did not send for me or any physician until one of them was practically dead Another case was in bed when I got there The glands of the neck were all swollen The mouth and the fauces as far as I could see were covered with membrane In a bed in the same room were two other girls, and from a room above there were two boys coming down In one of the cases there was evidence that it was going to be a very severe case I did not use any antitoxin in the worst case because it was too far gone To the others I gave antitoxin and I saw an immediate good effect At the first sign of the membrane in the children not yet affected I gave immunizing doses of 500 units and they all got well If you could have seen the cases with me, you would have believed as I do that those cases were saved by antitoxin Across the street there was a brother in law who called a physician who is a bitter opponent of antitoxin He did not use it and he succeeded in saving one of the four children In one family the Christian Scientists created quite a rumpus but nothing was done to them In that epidemic there was not a case died in which antitoxin was used and nearly all the other cases died Therefore I feel like saying what I said two or three weeks ago in our local society, that I believe today a man is criminally negligent of his duty who fails to give antitoxin in diphtheria

Dr John A Lockard—From my experience as interne in the New York Hospital, I wish to emphasize what has been said about the mortality In six months' experience there I have failed to see the membrane melt away any quicker with the antitoxin than without it I have failed to see the so called "black" diphtheria get well under the antitoxin treatment In one class of cases I saw a good result, and that was in the cases intubated In its effect on postdiphtheritic paralysis I have seen no results you could call good I have seen cases of heart failure with regurgitation just as marked and frequent As to the antistreptococcus serum, we found that most of the incubated cases died from subsequent pneumonias We took the cases with no physical signs of bronchitis on admission and injected the antistreptococcus serum, 2 c c every day Out of the six cases we lost five We found the rashes most confusing The rashes of this and scarlet fever were so much alike that barring the throat symptoms they would be very confusing I think, however, the statistics from the hospital are likely to lead us astray, especially in certain directions Usually the cases sent in are old cases The children have parents who are not particularly careful in observing the children and they do not recognize the disease until it is pretty well advanced Another way in which the statistics may err is that we admit many cases as diphtheria which upon bacteriologic examination would be called a mere tonsillitis In the children we do not have an opportunity to observe the melting of the membrane as well as in the adults, because we were required to give antitoxin to all the children But in adults it was optional, and we occasionally advised them not to take the antitoxin that we might observe the cases Side by side, cases as near alike clinically as we could possibly get them, I have seen the membrane melt away without the antitoxin and others who had antitoxin remained in the hospital weeks longer Another peculiar and significant fact, it seems to me, is that when our nurses become affected with diphtheria they do not use the antitoxin, and the same was true when my predecessor and successor had diphtheria

Dr H D Jerowitz, Kansas City, in closing—In respect to intubation, I might have had a great many more cases in my practice if I had been permitted to perform intubation when I wanted to, but as the majority of the cases were among ignorant people, they were very much afraid of mechanical treatment Many of these cases presented cyanosis, upon whom I wanted to intubate, and the majority got well just the same The difficult breathing seemed to be only transient It shows the fact that a great many cases that seem to require intubation or tracheotomy at the moment you see them, may have the spell pass off in a few momints and the case for the time being will be better Very often when these cases present urgent symptoms, the cyanosis and dyspnea are due not to the membrane, but more to the mucus, which may not be brought up a certain moment, and if an emetic is administered, or the child has a severe spell of coughing or crying, the urgent symptoms pass off and the necessity of intubation or tracheotomy is obviated As to the use of iron, we all have our own opinions, which are based upon our own experience I used iron in the early part of my practice, but I never could see the rationality of it, nor could I see why it cures these cases Besides, my experience is that the cases that can be benefited by iron, can just as well get well with other treatment I can not see what such an irritating remedy as the perchlorid of iron can accomplish in such a disease as diphtheria It seems to be a very irritating drug, not only constringing the membrane of the throat, but of the stomach and bowels as well, thereby interfering with assimilation I think the value of it is more from the chlorin, and for that reason I often use hydrochloric acid internally, expecting also an effect from it as it passes the throat As to the antitoxin, the dose must be large Two thousand units may be employed three times a day in laryngeal diphtheria One gentleman referred to the fact the statement was made that antitoxin does not prevent paralysis My paper did not say so I said paralysis occurred in those cases that were either severe cases or cases of long duration Those cases in which there was extension of the membrane or which lasted ten or fourteen days, were as a rule followed by paralysis Then I further stated that in all cases where the antitoxin is used early, the membrane disappears in two or three days and it shortens the sickness, and from this fact it prevents paralysis I stated that if the antitoxin was used early, no paralysis is found Now, as to the spread of diphtheria and the placarding, it is very evident that there are a number of mild cases that do not go to bed and are not recognized, and children having a very mild form of diphtheria, that are hardly sick except possibly a slight headache, may go to school and spread the infection to others

Dr F E Waxham, Denver, in closing—In regard to the paper presented by Dr McClanahan, I would agree entirely with his conclusions, so briefly and explicitly set forth In regard to the paper presented by the first essayist, I would say that on account of my confidence in antitoxin I have discarded all gargles, sprays, iron, and other remedies I simply give a large dose of antitoxin, repeat it in ten or twelve hours, and give a third or fourth dose, if necessary Antitoxin has been compared to vaccination I think that is not proper at all The vaccine disease is another disease, it is a disease, smallpox, modified by passing through the system of a cow There is simply no comparison between antitoxin and vaccination In regard to the health department, I was very much interested in the methods employed in Chicago They are quite different from the methods employed here Here the physician inoculates a test tube and takes it to the health department, if it is found to be diphtheria, the health department takes entire charge of the case They isolate the case, and make repeated examinations of the patient's throat As long as the case shows any bacilli in the throat, the case is isolated and the house placarded If Dr Jaques lived in Denver, he would not have the temerity to have the secretions of his throat examined I am much surprised that any one at this day, can oppose the use of antitoxin I can not understand how any one, after reading the conclusions of the Pediatric Society, can fail to be convinced of the utility of antitoxin After my experience in the treatment of diphtheria, I would feel that I was not doing my duty as a physician, not doing my duty to my profession, unless I [illegible] the use of antitoxin as the greatest remedy that has been presented to the medical profession during this century I can not but believe there must be something wrong in the methods employed by those who have found so little benefit from its use They either have not used the remedy early, or have not used the remedy in sufficient doses, or have not repeated it when necessary I suspect the cases that have come under Dr Welch's care are late cases, for frequently we know cases are sick three or four days before they are taken to a hospital Then, if a bacteriologic examination is made before treatment is begun, another twenty-four hours is lost I feel like agreeing with one of the speakers when he says that he would feel guilty of criminal negligence if a case died under his care and he did not use antitoxin

Dr H M McCLANAHAN, Omaha—I only wish to bear testimony that I believe most thoroughly in the use of antitoxin I believe, however, we must not expect everything from this remedy I believe the statement by Dr Welch, that antitoxin can not undo the harm diphtheria has done, is true I think the cases crowded together in the hospital will not do as well But I think his line of argument should not give us reason to not use the remedy in private practice In the cases mentioned by Dr Welch, I have no doubt he found mixed infection, over which antitoxin has no influence I think we should get a clear idea of what this remedy should be expected to do, and what it should not be expected to do I became thoroughly disheartened and discouraged with antitoxin The patients would be relieved a few hours, and then the patch would extend on down After the use of antitoxin in the past year I have intubated *only twelve cases, and eleven of them* have recovered I can go back five years, when the patients under tracheotomy or any other treatment that we had, gave a mortality of 50 or 75 per cent It would be a retrograde step if we were to allow ourselves to lose our faith in the use of antitoxin. But we should not expect it to do everything When your examination shows that you are dealing with a mixed infection, then let us not stop with the use of antoxin Then I believe nascent oxygen is of benefit Even some of those cases can be saved by the use of nascent oxygen, with antitoxin In one case I saved a child in this way when the lips were blue It leads me to believe I will never give up a case of diphtheria until the case is cold and stiff and dead I have the most profound belief in the value of antitoxin in neutralizing the toxins of diphtheria

THE EARLY DIAGNOSIS OF DIPHTHERIA

Read before the Mississippi Valley Medical Association, Oct 13 1898

BY WILLIAM K JAQUES, M D

DIRECTOR ANTITOXIN STAFF HEALTH DEPARTMENT CITY OF CHICAGO

Outside of laryngeal complications, the mortality in diphtheria is due to the toxin produced by the Klebs Loeffler bacilli No physician can successfully treat diphtheria unless he understands the nature of this toxin, how it is produced, and how the cells may *be fortified against its destructive action He must* understand that the Klebs-Loeffler bacillus is a distinct living entity or vegetable organism, that one of the products of its existence is diphtheria toxin, just as the result of the life of the yeast plant in alcohol

Other germs in anginas will cause inflammation, pain, temperature and membrane, but only the Klebs-Loeffler bacilli produce the deadly toxin which begins with their invasion and progresses to a fatal amount as swiftly as conditions permit

To appreciate the danger of his patient, a physician must understand the rapidity with which these bacilli multiply under favorable conditions The clinical symptoms manifesting their residence may give no indication as to the rapidity with which the fatal amount of toxin is being produced The best means of comprehending this fact is to use the microscope and follow the multiplication of the Klebs-Loeffler bacilli in their cultural life Inoculate a box of culture-medium with infected mucus and place in an incubator at body temperature At the end of three hours, a cover-glass pressed upon the surface, properly stained and mounted, will show sufficient bacilli, if they are present, to give an idea of the number and arrangement of germs upon the surface of the medium Incubate the same culture eight hours, and an examination will show that the germs have multiplied many times Eighteen hours will reveal a large and complete colonization, from which an idea can be gained of the way in which the Klebs-Loeffler bacilli multiply under favorable conditions Understanding, as we do, that toxin is a product of these germs, their multiplication means an increased amount of toxin, which soon reaches the fatal point unless checked by the use of antitoxin This demonstrates the importance of a physician knowing at the earliest possible moment what germs are present in an angina It may be said that in the majority of cases there are two things he does not know the extent of the infected area, and the resisting power of the patient

The diagnosis of diphtheria in the early stage of the disease must be made from both clinical and bac*terial evidence From his patient the physician finds* clinical manifestations of an invasion of the mucous membrane of the respiratory tract When his microscope reveals the germs that are causing this invasion, he can then say whether or not the disease is diphtheria Delay in ascertaining this information can only be done at great risk to the patient's life and the doctor's reputation

In order to ascertain the value of direct diagnosis, —by which we mean the examination of material taken directly from the infected area without waiting for incubation—the Chicago Health Department has introduced the following culture outfit for the use of physicians, a sterilized swab is placed in a glass tube, a slide carefully wrapped in paper is placed with this in an envelope together with a culture box and directions for using same Physicians are requested to inoculate the swab from the inflamed site, spread a little of the mucus upon the slide and allow it to dry The culture medium is inoculated from the same swab and it is returned to the glass tube The whole outfit is then to to be sent to the nearest incubator station or laboratory

As this method has been in use but a short time, its value has as yet to be demonstrated conclusively From my own experience I have received very valua*ble information In one case I did not find any Klebs-*Loeffler bacilli in the culture medium but found that a large colony of the bacilli had incubated upon the mucus which was still left upon the swab In a number of cases I have been able to make a direct diagnosis by staining and examining the slides as soon as they come to the laboratory When no antiseptic treatment has been administered before the culture is taken, and the disease manifests malignancy, by stupor, hoarseness or swelling of the cervical glands, it has been possible in about 50 per cent of the cases to find sufficient bacilli to warrant a diagnosis of diphtheria, sometimes before any trace of membrane is visible When it has been possible to get a small portion of membrane to spread on the slide, there has been no difficulty whatever in about 75 per cent of the cases in making a direct diagnosis

Cases in which the Klebs-Loeffler bacilli can not be found by direct examination will lose very little by waiting for incubation of the culture

A bacteriologist can not be sure that his examination reveals the true condition of a case unless he knows the material was correctly obtained In a laryngeal case, mucus from the mouth may not have become infected sufficiently to show the bacilli present This may also be true with an invasion of the cervical glands, but if a piece of membrane is obtained from the tonsils and found not to contain the Klebs-Loeffler bacilli, the probabilities are that it is not diphtheria

In large cities, where examinations are made by the bacteriologists of health departments, a physician may perhaps be pardoned for not acquainting himself with the technique of examinations At the same time, the more a physician knows about the bacteriology of diphtheria, the more accurate will be the results from the perfectly taken cultures which he sends to the laboratory One of the greatest disadvantages we have to labor under is the faulty manner of making cultures by physicians who know nothing of bacteriology Even if the culture is recognized as imperfect before incubation, it means at least a few hours' delay in securing another

Because of the contagious nature of diphtheria, the health departments of large cities have been making bacterial examinations for physicians, and the success of the work in controlling and limiting the disease, as well as its statistical value, has justified the expense As long as there was no specific for diphtheria, the diagnosis was not of such vital importance Physicians could prescribe local treatment and await developments Now that we have a remedy which, when properly used, may truly be called a specific, and when the life of the patient depends upon an accurate diagnosis, the responsibility of the attending physician is very great

In the malignant form of diphtheria nearly 50 per cent of the cases die unless proper treatment is administered Any physician who neglects to make a correct diagnosis during the time when the remedy is efficacious—that is during the first two or three days —is responsible for the result He is responsible because it is within his means to obtain the knowledge which will make him competent to treat the disease intelligently, and therefore successfully He is also further responsible in permitting the continuance of infection to endanger the safety of the community The technique of the bacterial diagnosis is simple The entire outfit for this work may be obtained for less than one hundred dollars The essentials may be acquired at home by any physician who is willing to devote no more than his leisure moments to it

The users of antitoxin everywhere emphasize the importance of its early administration In a paper by Dr Edwin Rosenthal of Philadelphia read at the meeting of the American Medical Association in Denver, he gave a statistical record of sixty cases in which he administered antitoxin, with nine deaths The recoveries are not more instructive than the deaths, in all of which the record shows antitoxin to have been administered from the third to the ninth day The child who received the antitoxin on the third day died of bronchial pneumonia The other cases, all being in an advanced stage, illustrate in a forcible manner that antitoxin had not been given until after the destructive action of the toxin, against which no remedy is proof

To demonstrate the protective value of antitoxin, the following experiment has been conducted On October 10, in the presence of Dr F W Reilly, assistant health commissioner of Chicago, Dr Wynekoop, assistant bacteriologist, and myself, Dr Adolph Gehrmann, city bacteriologist of Chicago, injected nine guinea pigs with four times fatal doses of diphtheria toxin The first three were immunized two days previously by the injection of 1 c c each of Parke, Davis & Co 's antitoxin The next three received 2 c c of the same antitoxin each, following the injection of toxin The third three have had no treatment whatever since the injection of the toxin The pigs are here, and are correctly labeled as to condition, which presents decided effects on this, the fourth day All pigs that received antitoxin are alive and apparently well Of the three not protected, two are dead The third, being still alive, would indicate the possession of natural immunity against the toxin

From my connection with the Chicago Health Department, four years ago, to the present time, our efforts have been directed toward obtaining an early diagnosis in all anginas, and supplying a reliable grade of antitoxin The best methods of work have been studied and established, with a view to assisting physicians by furnishing such facilities for the diagnosis and care of contagious diseases as they might not have themselves As a result, our department corps of inspectors are doing harmonious work and our success in controlling diphtheria is demonstrated by the decrease in mortality from 38 per cent, not including laryngeal cases, to 6 7 per cent, including all forms of the disease During the month of September, the department treated 108 charity cases, 66 of which were bacterially verified as true diphtheria, with three deaths Two of these cases were in the last stages of toxin poisoning when the inspector was called It has become possible by improved methods to give a physician a diagnosis within an hour from the time he makes his first call, if a direct examination can be made, if not, he receives his answer in from six to ten hours from the time the specimen is received

It is fair to assume that our remarkable success in controlling and limiting diphtheria is due to the methods employed, the most important rule of which is, *first and always secure an early diagnosis then lose no time in applying the remedy*

SOCIETY PROCEEDINGS

Mississippi Valley Medical Association

Twenty fourth Annual Meeting, held at Nashville, Tenn, Oct 11-16, 1898

First Day—Morning Session

The association met in the hall of the House of Representatives at the State Capitol, and was called to order by Dr Duncan Eve, chairman of the committee of arrangements Prayer was offered by Rev James I Vance D D Addresses of welcome were delivered by Hon J M Head, on behalf of the city and State, and Dr C S Briggs, on behalf of the profession of Nashville

Dr John Young Brown of St Louis delivered the President's Address, after the reports of the secretary and the treasurer had been read and accepted He selected for his subject, "The Mississippi Valley Medical Association" and dealt with the history of the association, saying that it was organized twenty four years ago Its rapid growth is due to the loyalty of its members and to the fact that from its inception it has been a distinctively working body, it has never been a mutual admiration society He gave suggestions for its improvement, and said that inasmuch as the association contemplated the publication of an annual volume of Transactions, he would suggest that the dues be *raised from $3 to $5*

Dr **Charles T McClintock** of Detroit, Mich, read the first paper, which was entitled

IMMUNITY

Of late years a large part of the laboratory work in medicine has had to do with immunity Many facts have been discovered, in a few instances these have been of immediate practical value in the treatment or prevention of disease But for the most part these facts are uncorroborated, often contradictory, their meaning not clear Hypotheses have been advanced, but as yet we have no theory that will even approximately explain the facts of immunity The future of work in this line is full of promise For the infectious disease at least, immunity and cure are one and the same A diphtheria patient will be cured only when his tissues are immunized against the attack of the diphtheria poison There are several kinds and various degrees of immunity We have a natural and an artificial or acquired immunity, apparently these are entirely different in kind, dependent on different functions of the body, effected by different substances There is racial immunity Again, we have *an immunity correlated with age Variations in suceptibility* are noted in different varieties of the same species and even in different families Again, there is an individual immunity Still again, one part of the body, even one portion of the same tissue, may be immune, while the rest is very susceptible *These facts are not to be explained by general resistance, good* health, etc The most vigorous man may acquire smallpox or influenza The healthiest cow is likely to take pleuropneumonia

Metschnikoff's theory—phagocytic—is the best explanation we have for natural immunity Nuclein seems to be the germicidal agent elaborated by the white corpuscle If natural immunity is due to one or to several chemic agents, it follows that it is limited Chemic action is always greater than life

After recovery from an attack of certain of the infectious diseases, there is more or less of immunity to that disease In some instances, as in scarlet fever or syphilis, this acquired immunity generally lasts for life The immunity following recovery from disease is not proportional to the intensity of the disease process The ability of an organism to resist the attack of disease germs or their products can be increased, trained, *educated, if you will Thus, in producing diphtheria antitoxin,* we often get our horses to bear without apparent harm several times the fatal dose for an untreated horse It may happen that diphtheria or measles may, after generations or centuries, disappear, owing to the fact that the race becomes immune

To what extent an acquired immunity can be inherited is both an interesting and important question This sort of immunity is usually lost, at least so far as our tests show, before the animal reaches the adult stage This inherited immunity is not the same as the immunity of the suckling This is due to the fact that the immunizing bodies pass into the milk The child receives from its mother not only food, but disease resisting power We have active and passive forms of acquired immunity The horse producing antitoxin is actively immune, his tissues are producing antitoxin The child receiving a dose of antitoxin is passively immune It has borrowed the strength of the horse There is an *immunity to poisons* The wolf thrives on putrid flesh Some animals are immune to snake poison The insusceptibility of the morphin user may be something *more than mere tolerance The drug may be, in part,* destroyed, and this anti power may have to do with the craving for the drug

There is no satisfactory explanation for the facts of acquired immunity The various theories as to the nature of antitoxin and its mode of action were given, with the conclusion that *antitoxin, in some way as yet unknown, stimulates some por*tion of the body, and this in turn destroys the poison There is no antitoxin but in short, an immunizing body Immunity and cure are the same thing

Dr **George W Johnson** of Dunning, Ill, has had some experience with nucleinic acid in the treatment of pulmonary tuberculosis in cases of mixed infection, and has noticed a *diminution in the number of pyogenic bacteria*, and asks whether the phagocyte attacks the tubercle bacillus the same as it does pyogenic bacteria

Dr **McClintock** replied that he knows of no reliable investigations that have been made with reference to that point

Dr **Ernest B Sangree** of Nashville said it is believed by many investigators that the phagocytes eat live tubercle bacilli, and that cases in which tubercle bacilli are included in the phagocytes have a better chance to get well than those which do not contain them

Dr **Dudley S Reynolds** of Louisville is afraid that experimental observers have failed to note the necessary equilibrium *between the circulating blood current and the lymph stream* He elaborated the theory of phagocytosis, and showed how phagocytosis can never be successful if obstructions exist in *the lymph channels*

Dr **C L Minor** of Asheville, N C, presented a paper entitled

HYGIENE VS DRUGS IN THE TREATMENT OF PULMONARY TUBERCULOSIS

Under hygienic and dietetic treatment the author embraces all such non medicinal measures as are directed toward an *increase in the vitality of the organism and of its resistance to* disease, and remarks that climato therapy is but a branch of hygienic treatment, although he does not embrace it in his remarks, which are confined to the proper application to individual *cases of exercise, gymnastics, massage, hydrotherapy,* rest, sleep, diet, amusements, clothing and quarters A partial and unsatisfactory use of such measures is more or less general, but unless directions be definite and specific, they will fail of their purpose The difficulty of getting a patient to yield implicit obedience to the doctor was dwelt on, the indefiniteness of the orders given being in part to blame If he is to recover, the patient and doctor must both work hard, no half hearted seekers for pulmonary health being likely to recover The necessity of carefully and fully writing out exact orders for every detail of the patient's life, to be followed religiously by him, was urged, such a prescription in phthisis being of more value than the more common one for drugs All such measures were, for convenience, classed under three heads Those affecting the patient's surroundings, those affecting his life and those affecting his exercise The very common abuse of exercise was deplored, and the invariable rules were stated "*Exercise short of the point of fatigue*," and "*no exercise with* a temperature over 100 4 degrees" Following these no mistake can be made

A very gradual accustoming of the patient to longer and longer walks, beginning with only fifty or a hundred yards in many cases, and increasing until finally from two to ten miles can *often* be easily tolerated, and a judicious use later on of walks on increasing incline till steep hills are easily surmounted, is warmly recommended Pulmonary gymnastics was most especially dwelt upon for use in non active cases, and among several methods for chest development and the increase of vital capacity, that form of Indian club swinging called the "double figure of eight" was chiefly recommended

Finally any intention to advocate nihilism in medicine was denied In carefully selected cases certain drugs have undoubted value as adjuvants, never as the chief resource The short life of most drugs in *phthiso therapy was noted* and ascribed to the fact that no man can treat this disease long and not realize that nothing that in the *least* degree upsets the stomach can be anything but a curse to the patient The only valuable results are those based on a vitalizing of the whole system, a stimulation of metabolism on a strengthening of the cells to oppose the invader The thing to be attacked is not so much the lesion in the lung directly as the lowered vitality of the body, the diminished capacity of the lungs, and the deficiency of appetite, and drugs directed to a conquering of the bacillus *in situ*, are not to be compared with measures which enable the organism itself to acquire the strength to overcome disease These things can be brought about best by an improvement in nutrition, which must after all come from the stomach, and an increase of the amount of oxygen taken into the lungs Air and food are the drugs to which we can always trust, they will never deceive us If a patient can be taught to get both in good amounts wherever food can be assimilated and enjoyed and air breathed deeply, there is hope of cure Throw away two thirds of our medicine bottles and use the other third less often, carry out a hygienic plan of life, stimulate the appetite by nature's appetizers—air and exercise—which are alone permanent in their results, and which are as superior to gentian or quassia as sunlight is to darkness

Dr **S C Baldwin** of Salt Lake City contributed a paper on

CONGENITAL SCOLIOSIS

Scoliosis is the most common of all deformities, it is most often found in children under ten, rarely beginning after eighteen, it is found more often in girls, in the ratio of five to one, the etiology is in a large number of cases very uncertain Congenital scoliosis is very rare Tubley, of London, in the latest English work on deformities, says that he has been able only to verify four cases

The case reported by the essayist was first diagnosed as scoliosis when the child was twenty one months old, but the father had noticed the "lump" ever since the child was first washed The interesting features of the case are that the curvature is in the lower cervical and upper dorsal region There is some pressure on the cord, as shown by the more or less deficient development of the right side The convexity of the curve in this case is to the left There is partial paralysis of the fore finger of the right hand There is sweating and flushing of the left side with none on the right

The cause of the scoliosis in this case is thought to be the lack of amniotic fluid while in utero, probably allowing the muscular walls of the uterus to press on the fetus and hold it in a faulty position, and in this way cause a wedge shaped development of the bodies of the vertebræ This theory has been advanced by Weissenberg, Hirsh, and Schauz in the last year In this case the mother was very small, and passed at the time of confinement so little water that she did not know there was any, and felt no motion comparatively during pregnancy

Dr **Samuel E Milliken** of Dallas, Texas, has seen one case of scoliosis in a child under one year of age, but he is not prepared to say whether it is congenital or not

First Day—Afternoon Session

Dr **William L Baum** of Chicago read a paper on

THE THERAPEUTIC VALUE OF MARMOREK'S SERUM

He dealt with the literature of the subject in an exhaustive manner Twenty two cases have come under his observation in which the serum was used Of these, nineteen were cases of erysipelas, one of erysipelas plus tubercular nuchal glands, one of facial erysiplas during childbed without septicemia, and one of erysipelas with puerperal septicemia and double labial abscess The last was the only fatal case

The deductions he draws from an analysis of the literature and his own experience are 1, in pure streptococcic infections the serum undoubtedly exercises a favorable influence on the course of the disease, 2, in the mixed infections the influence of the serum is noticeably demonstrable, but it merits further trial as an adjunct to other treatment, 3, considering the grave character of the complications of a nonstreptococcic nature reported, ordinary rules of therapeutics demand that in such cases, as with the diphtheria antitoxin, all indicated therapeutic procedures must be employed as well as the serum, 4, in view of the fact that erysipelas streptococci and phagocytes have been found to exist side by side in the lymph channels, it is fair to assume that the influence of the serum is directly exerted bacteriologically on the streptococci and not entirely through a stimulation of phagocytic action, 5, the initial dose in all cases should be 20 c c, to be followed by 10 or 15 c c, according to the indications, every twenty four hours

Dr **Charles L Minor** said his experience is practically confined to secondary infections in tuberculosis He had used the serum of Parke, Davis & Co, with considerable satisfaction, in preference to Marmorek's

Dr **Samuel E Milliken** has used antistreptococcic serum in two cases, both of which terminated fatally One was a case of abscess of the liver, the other a suppurative appendicitis

Dr **William K Jaques** of Chicago, called attention to infections in the pulmonary tract that he has found to be purely streptococcic, and in such cases he has advised injections of antistreptococcic serum with good results

Dr **Baum**, in closing, emphasized the importance of diagnosing the kind of infection present

Dr **Albert Bernheim** of Paducah, Ky, presented a paper and reported three cases of syphilis, in which he administered blue ointment with satisfactory results by the mouth He urges a thorough trial of this method, believing it will please the patient as well as the physician The method of administering blue ointment by inunction is disliked by the patient on account of its nastiness and inconvenience, hence if another method of using the ointment can be substituted with the same good and quick results why not do so?

Dr **James T Whittaker** of Cincinnati, delivered the Address on Medicine, selecting for his subject "Diabetes Mellitus"

Dr **Andrew Timberman** of Columbus, Ohio, followed with a paper entitled

MASTOIDITIS WHEN TO OPERATE AND HOW

The causes and symptoms of this affection were described To know when to operate one must be able to exclude the diseases which are often accompanied by inflammatory conditions over the mastoid, without actual involvement of the bone, and which quickly recede when the primary disease is properly combated Every physician in his experience sees cases of simple furunculosis, and diffuse external otitis presenting as marked symptoms, painful and swollen mastoids The tissues are boggy and the edematous condition is determined by palpation and pain on pressure Such disease, as well as syphilis, must always be excluded as a *sine qua non* before the operating

He divides cases of mastoiditis into two classses, the first comprising those complicating acute aural disease, the second class, those complicating chronic aural affections This division ignores primary mastoiditis, which is very infrequent

The conclusions arrived at were Operative measures should be instituted 1, to preserve the function of hearing as well as to prevent a fatal issue, 2, earlier in mastoiditis due to scarlet fever, diphtheria, and the worst cases of influenza than when due to colds, measles, typhoid fever, etc., 3, in the acute cases of mild infection, when subsidence does not occur within at most eight days (Schwartze), but the shorter period is safer in a virulent infection, 4, recurrent mastoiditis due to any cause, 5, in mastoiditis complicating a chronic suppurative otitis, 6, in acute cases when there is a drooping of the lining membrane of the superior posterior wall of the external auditory canal, carrying with it the membrane Shrapnelli, in chronic cases when at the same place a crater like opening leads to the recessus epitympanicus and aditus ad antrum, even though in neither case symptoms immediately menacing life be present

The author favors the typic or original Schwartze method of opening the mastoid antrum Its success in given conditions justifies its application, its failure in given conditions has resulted in a more perfect procedure styled the Schwartze Stacke, or radical operation

Dr **J Homer Coulter** of Chicago maintains that the general practitioner should not treat cases of mastoiditis in which the symptoms are well defined, and no one who has not had considerable surgical experience should attempt the Schwartze operation

Dr **J A Stucky** of Lexington said that in many cases of necrosis of the malleus he has made a free incision along the posterior superior wall of the canal, curetted the diseased bone away, tamponned the canal lightly with iodoform gauze, and patients have done well without undergoing the radical operation

Dr **Dudley S Reynolds** laid stress on the importance of instituting constitutional medication in the stage of invasion in cases of mastoiditis, saying that an ounce of prevention at this time is most preciously bestowed

Dr **L B Graddy** of Nashville called attention to a point not mentioned in the paper—the differential diagnosis between mastoiditis and mastoid periostitis If cases are carefully observed there is as much difference between the two conditions as there is between a periostitis of the tibia and an epiphysitis This differentiation is of permanent importance in the treatment, whether it be medical or surgical

Dr **J Homer Coulter** of Chicago read a paper on

PROPHYLAXIS IN NOSE AND THROAT DISEASES

He said that there are many preventable pathologic conditions in the nose and throat, and that many of the ordinary diseases of this portion of the anatomy have evoluted into more serious and distinctly different affections, will be admitted without question He omits any reference to such conditions as syphilis, tuberculosis, diphtheria, influenza, or the exanthemata, inasmuch as the possible prophylaxis in each affection is a matter of general knowledge He also omitted reference to any technic details which are at best mooted points with authorities

Surgery does not cure all conditions, nor does it even prove always a prophylactic blessing So also do local applications and constitutional treatment prove unavailing if universally depended upon This is due, in a measure, to the lack of carefully exacting and eliminative diagnoses With the development of our knowledge of the physiology of the nose and throat have come, also, new ideas of the connection between many diseases of those organs and of their relative etiologic importance The impairment to ventilation and drainage is a most important factor, and one usually amenable to surgical treatment. "Taking cold" is not only a most frequent condition, but one the most susceptible to prophylactic measures Clothing of the entire body is a factor of paramount importance in prophylaxis Too much clothing about the head and neck is just as disastrous as insufficient protection Adenoids polypi, spurs, exostoses deviations, deflections, and sensitive areas, are each am[illegible] to [illegible]l treatment and demand such interfere[illegible] d ([illegible]ther hand, too much su[illegible] as [illegible]onserva tism The t[illegible] conditions as should be recognized as a most significant danger signal Anything which produces an alteration in the normal physiologic metabolism of the mucous membrane of the nose and throat, any alteration in the nutrition of the parts, any abnormal variation in functional activity, any considerable change in the histologic anatomy, are each and all remedial surgically or otherwise, and are, therefore, amenable to prophylactic efforts

Dr J A Stucky of Lexington followed with a paper entitled

PERITONSILLITIS OR QUINSY CAUSE AND TREATMENT

Of ten authors consulted, seven, after citing hereditary predisposition, exposure, etc, mention rheumatism and gout as the most prolific causes of this malady Close observation and careful testing in selected cases, convince him that the rheumatic, or more probably the uric acid diathesis, has more to do with the causation of this disease than any other factor

Coming to the treatment, he believes, if the majority of cases of quinsy are seen within forty eight hours after the first onset of the disease, they can be aborted to such an extent that suppuration will not take place In cases that progress to suppuration, he strongly advocates early and free puncture, just as soon as there is marked distention, in order to relieve pain and stop the destructive suppurative process For this purpose he uses a modification of an ear spoon, first described by Spier, and not a knife

(To be continued)

The Chicago Society of Internal Medicine

Second Regular Meeting, Sept 21, 1898

(Continued from page 984)

Dr Daniel R Brower read a paper before the meeting entitled

ACUTE CEREBRAL MENINGITIS OBSERVATIONS ON ETIOLOGY, DIAGNOSIS AND TREATMENT

Cerebral meningitis is, in all the large cities, a formidable cause of death In some years it is surpassed by but few causes of death The following table shows this, as well as emphasizes the fact that the ordinary therapeutic measures are of no avail

DEATHS FROM MENINGITIS IN CHICAGO

1860	1	1891	1,311
1865	21	1892	1,125
1870	172	1893	1,452
1875	255	1894	1,220
1880	408	1895	764
1885	528	1896	606
1890	817		

These figures are much the same as those of other large cities, and show the necessity of a more careful study of the cause, prevention and treatment of this class of diseases The cerebral membranes are favorably placed for the development of bacteria At least nine micro organisms have been found present, doubtless as causative factors in cerebral meningitis, as follows Pneumococcus lanceolatus, diplococcus intercellularis, streptococcus pyogenes, staphylococcus pyogenes aureus, bacillus tuberculosis, bacillus of Eberth, bacillus coli communis, streptococcus seiferti and the gonococcus

The classification of meningitis to be scientific should be based upon its causative, and it is therefore necessary to determine in each case the micro organisms that may have produced it, and herein the difficulty lies Lumbar puncture, and the chemic and bacteriologic examination of the cerebro spinal fluid obtained will enable, in some cases, a differential diagnosis to be easily made This lumbar puncture is a trifling operation It consists in passing a needle into the subarachnoid space between the third and fourth lumbar vertebræ in adults, or between the fourth and fifth lumbar vertebræ in children, about 5 mm to one side of the median line For young children the ordinary hypodermic needle is sufficient, for adults a larger and longer needle is necessary The fluid obtained should be tested first for albumin, but in acute inflammatory conditions the amount is considerably increased, it may be 1 or 2 per cent Then the examination should be made for pathogenic organisms, and when found the diagnosis is complete The Skeer sign, if present, will enable a diagnosis of tubercular meningitis to be made very early This sign was described by me in the Journal of the American Medical Association, Jan 7, 1888, and observed by the late Dr I D Skeer of Chicago twenty years before It is due to the deposition of the tubercle around the pupillary margin of the iris It shows itself first as a distinct wreath of white clouds about a millimeter from the margin (see Fig 1) This sign occurs before any change has taken place in the pupillary orifice After three or four days these minute, cloud like masses disappear and a yellowish, round circle takes their place (see Fig 2), becoming more attenuated as the pupil dilates These secondary changes are doubtless due to degeneration of bloodvessels and tissues from the tubercular deposits Unfortunately, this sign is frequently absent, but when present is pathognomonic of tubercular meningitis

Treatment —A dark, well ventilated, quiet room should be found The patient's should be shaved and surrounded by ice bags, leeches should be applied over the temples, the pain should be mitigated by morphin or antipyrin hypodermatically, the temperature should be reduced by cold sponging, the bowels should be freely moved by calomel, and there should be applied freely to the scalp every day a 10 per cent solution of iodoform The difficulty of medicating these cases by the mouth, led me to adopt the treatment by inunction about fifteen years ago, first with mercury without any success, and then with iodoform with some success Absorption usually takes place promptly, so much so that I have been able to detect the iodin in the urine and saliva one hour after inunction The amount absorbed can not be very great, inasmuch as I have never seen the untoward effects that sometimes follow the use of iodin in open wounds, and I have used in the treatment of a case as much as ten grams of iodoform I have suggested this treatment in consultations in at least a hundred cases, but have been able to get the results in the following cases only

	No of cases	Recoveries	Deaths
Dr J S Hunt (deceased)	8	6	2
Dr J W Fitzmaurice	6	4	2
Dr P H Conley	2	2	0
Dr M Leevenson	2	1	1
Dr W D Neal	10	6	4
Dr David O'Shea	7	6	1
Dr William Martin	2	1	1
Dr G W Reynolds	3	3	0
Dr J C Craig	1	1	0
Dr D R Brower	6	3	2
Total	46	33	13

In one of the cases that died in the practice of J S Hunt, and of the cases I have reported as terminating fatally, the Skeer sign was present, making the cases tubercular meningitis In the other fatal case I have reported, lumbar puncture determined the bacillus tuberculosis to be present The diagnosis in these cases was made by the attending physician and myself, and any one of those whose names appear in the list are perfectly competent to make a diagnosis Indeed, there are none more so Many years of practice and excellent scientific attainments are qualifications of them all Some of these cases were exceedingly unfavorable, notably the case of Dr Craig, that did not seem to offer the slightest hope of recovery

I trust that this communication will result in a more general use of this plan of treatment in this perplexing class of cases, and that it may aid in diminishing the great mortality from meningitis found in our city health reports

Dr W D Neal—It is a matter of surprise to me that Dr Brower brings this question up this evening I have not given the subject any thought for quite a while These cases were given over the telephone, and I am not sure there was a correct understanding as to the remedies employed in all of them If I remember correctly, two of these cases recovered where I did not use the inunctions It was before I began their use It may be possible that in one of these cases the diagnosis was not clearly made out The percentage of recoveries given here looks high, and the same ratio might not have been maintained if carried farther There were other elements brought to bear in some of these cases which I thought cut quite an important figure, at least, I put a good deal of stress upon the minute doses of calomel particularly in younger children It might have been the inunctions, but I have a good deal of confidence in minute doses of calomel often repeated I do not know how it acts, but I am sure I have had good results from the use of the inunction and calomel combined I have not kept any data of my cases since talking to Dr Brower, and I am inclined to think that the percentage of recoveries has not run so high, but I have come to the belief that the disease is not necessarily fatal, and that the mortality can be greatly reduced by this method of treatment

Dr M L Goodkind—I should like to ask if there are not a great many cases simulating meningitis that occur in infectious diseases, particularly in children, such as pneumonia, and intestinal toxemia, which get well spontaneously with the subsi dence of the malady producing the meningeal symptoms, cases of opisthotonos with convulsions and general rigidity, with contracted or dilated pupils—cases that can not be called meningitis, although they closely resemble it Possibly that may be an explanation of some of the cases recovering under calomel and iodoform inunctions

Dr Sanger Brown—I would like to briefly call attention to one aspect of this subject, and that is regarding the differentiation between pseudo meningitis and acute meningitis I think this is a point which frequently perplexes the practitioner, and one on which we would like some light It often happens to those of us who do some consultation work to find that between the time the practitioner decides to call a consultant and the time at which the consultant arrives the symptoms will have sufficiently declared themselves in one way or another so that then it is comparatively easy to make a diagnosis

It must be admitted that in a great many conditions, especially in children, it is impossible to determine, often for many hours, whether we have to deal with a case of pseudo meningitis or a case that will afterward become an undoubted acute meningitis I think we are warranted in the assumption, now that it has been discovered and pretty well demonstrated that so many different kinds of bacilli are competent to act upon the meninges and produce meningitis, that the symptoms that we get in many of the infections are probably due to the action of a bacillus or bacilli upon the meninges, and that, as the process advances, there is a concentration of the bacilli to some place or organ for which they have a greater affinity, and the meningitis aborts, so to speak I think this is a more rational view to take of the subject than to assume that the pseudo meningitic symptoms are due always to the action of a morbific influence in some remote part or organ, that is, to reflex action

I was struck forcibly with this recently in consultation where there were at first marked symptoms of pseudo meningitis, which disappeared in the course of a few days, and pronounced symptoms of acute anterior poliomyelitis declared themselves The attending physician, who was a very competent man, and had of course seen a great many cases of actual meningitis in his practice, felt sure that he had to deal with a case of this disease There was well marked opisthotonos, vomiting, and constipation lasting for a day or two, when the mother, who was herself the daughter of a physician, noticed that the child was not using the lower extremities and one arm as much as she thought it ought to In the course of a day or two all the pseudo meningitic symptoms entirely disappeared, and when I saw the case, ten days later, it was one of well marked acute anterior poliomyelitis Now, we have every reason to believe that acute anterior poliomyelitis is due to infection, and we know that acute meningitis is so caused I think this hypothesis is well worthy of our consideration, and it derives further support from the fact that as a general rule, in cases of patients dying from actual, well marked attacks of acute meningitis, in quite a large proportion we find very much less evidence of disease macroscopically in the meninges and cortex than we should have been led to expect, and yet we can have no doubt that the action of these microbes upon the membranes and cortex produced the meningitic symptoms I repeat, then, that it is not a difficult matter, at least according to the view I take of it, to infer that many of the symptoms in so called pseudo meningitis are actually due to the action of bacilli upon the meninges and cortex, and that they rapidly subside, either by destruction of the microbes that caused them, or that these abandon the meninges and concentrate in some other part of the economy, giving rise to this or that type of infectious disease

That shock, however, caused by intestinal irritation or extensive superficial burns, for instance, may excite convulsions in children, must be freely admitted

Dr R B Preble—The thing which impresses me most in this report is the wide difference between it and the mortality which we are led, both by our reading and experience, to believe prevails in meningitis If we take from the table the 4 cases which are admitted to be tubercular we have 42 cases with 33 recoveries, that is a mortality of 25 per cent for a disease which all authors agree is almost invariably fatal, with the exception of meningitis which is classified as epidemic, and even in this form the mortality ranges anywhere from 80 to 20 per cent, the cases toward the end of the epidemic being milder and averages about 37 per cent We must, therefore, be strongly impressed by a report in which the mortality is about 25 per cent, especially when we consider the fact that the therapy has undergone no radical change, we have here nearly the same therapeutic measures which have been employed for years and which have been, not given up but regarded by most authorities as having little more than a palliative effect

There are a great many conditions which simulate meningitis, nephritis for one, it being not uncommon for uremia to simulate meningitis, and the differentiation can be made only by an examination of the urine or a postmortem, in which the brain will be found in a normal condition or showing but little hyperemia or edema Another condition, which frequently gives rise to such meningeal symptoms, such as isolated paralysis of the ocular muscles, can occur from sepsis, just as it can occur from nephritis Personally I have seen a number of cases which clinically closely simulated meningitis, the simulation going far enough to pick out separate eye muscles, separate cerebral nerves for paralysis, but postmortem showed the cases were not meningitis I have seen other cases which I believed were meningitis that recovered, and I could only say that I was not certain I have only seen one case where I was sure that it was meningitis That case I saw recently in Dr Butler's ward at the County Hospital The man gave the usual initial history of meningitis, facial paralysis, choking of both discs, pure culture of the meningo coccus from the fluid gained by lumbar puncture, and yet he recovered I feel reasonably sure that in this one case I saw meningitis recover There are a few cases of tubercular meningitis in which recovery has taken place Elham records one case of recovery after lumbar puncture with demonstration of tubercle bacillus Eichhorst has one case Luebe had one case, and Koliako of Vienna had a case

In view of the wide difference between Dr Brower's results and the general opinion of the mortality of meningitis, we must demand more accurate details of the individual cases, before we can accept this table and before we can adopt the use of the iodoform inunction with any confidence

Dr H M Lyman—More than thirty years ago I had from the late Dr Bevan an interesting pointer in regard to meningitis I had a little patient whom the year before I had rescued from death by furnishing a wet nurse when he was starving, under the care of a homeopathic physician who did not believe in wet nurses, consequently I felt a good deal of interest in the case After recovering from the perils of lactation and early dentition, he was finally attacked with symptoms which I attributed to tubercular meningitis The classical symptoms were all present and I had no doubt of the result I called in Dr Bevan, who suggested that it might be pseudo meningitis and was probably due to some disturbance of the digestive organs He advised the use of small doses of calomel with tincture of belladonna, and in a few hours the photophobia, the irritability and other evidences of meningitis subsided and in a few days the patient made an excellent recovery Since then I have seen a number of such cases, and I think it would be well for us to recall to mind the fact that the onset of very many diseases, especially with children, is apt to be exceedingly severe and that many cerebral symptoms are prominent which would lead us to believe that they are really due to congestion of the meninges, and yet it will all clear up in a short space of time, with or without treatment So in analyzing a table of this kind, for the city record, especially, I think it would be desirable to have an accurate statement and description of the characteristics of the cases before we decide as to the results of any form of treatment

With regard to the symptoms involving the iris, I used to see some of these cases with Dr Skeer It was his belief that they were due to local tubercular deposit but I was never able to discover anything of the kind, the appearance depicted in the iris appeared to me to be due to effusion of an inflammatory character When tuberculosis involves the eye, tubercle is usually deposited in the choroid and does not manifest itself in the iris I am not able to find any description of tubercle upon the iris, but this peculiar formation in the iris is not so very uncommon, and is a very interesting symptom when present, though by no means as diagnostic as Dr Skeer was led to believe In those days the matter had not received attention and been described in the books as it now is, but now it is a well known symptom So far as the treatment is concerned in tubercular meningitis, you must rember that recoveries occasionally occur, but it has long been noted that patients who are supposed to recover from tubercular meningitis are liable to returns of the disease Certain foci of tuberculosis in a distant part of the body perhaps, would disseminate tubercular germs and there would be a temporary inflammatory condition lasting for a time, the patient apparently recovering from that, then there would be another scattering of seed upon susceptible soil and another attack which usually proves fatal So where there is reason to believe that there is tubercular meningitis temporary improvement or apparent recovery should not lead us to flatter ourselves that recovery has actually taken place any more than in tuberculosis of the lungs where a tubercular focus having formed giving rise to symptoms which have subsided, should lead us to suppose there is a final recovery, it is simply a stage in the disease Tubercular meningitis is almost invariably fatal in the first or second attack So far as the disease Dr Brown has alluded to as pseudo meningitis, is concerned, connected with spinal disease, it is a well recognized fact and I have seen a number of cases of the kind, that the onset of true poliomyelitis is attended with a violent reaction of a similar character, the disease frequently in its onset resembles clinically the ordinary form of spinal meningitis I have not seen a case resembling tubercular meningitis, but I have seen cases resembling epidemic spinal meningitis in the early stage, then points of differentiation appear so that finally the diagnosis is cleared So far as lumbar puncture is concerned, that is advisable as a means of investigation in asylums and hospitals where you can treat your patients as so many blocks of wood, but in private practice it is almost out of the question, and I think it would be advisable to reserve that method of investigation for selected cases I should not recommend it to be employed in general practice, for with such treatment you would lose a great many patients The result is uncertain, as has already been intimated, and you may make a puncture and get one kind of microbe, while another form that is producing fatal results will pass undetected So with regard to the treatment of the disease this much may be said that in the worst forms of tubercular and epidemic cerebro spinal meningitis there is no remedy that is of much value You can palliate, but you will rarely succeed in curing In the milder forms of the disease there is more hope The patient dies from the poisonous toxins that circulate through the fluids of the body, therefore, if the kidneys are active, if the liver is efficient, there will be a better chance of recovery Calomel is a positive diuretic, it does stimulate the action of the kidneys, it stimulates somewhat the action of the excretory functions of the biliary organs, and furthermore it intensifies the activity of other remedies As for iodoform, a patient with a shaven head daubed with ointment produces a very imposing effect upon the bystanders, but so far as its absolute potency in curing the patient is concerned it is very doubtful Its use has been pretty generally abandoned in the European hospitals where it has been tried

Dr H T Patrick—Ever since I was an interne in the Infants' Hospital in New York, some fourteen years ago, I have been slow in making a diagnosis of meningitis We had a lot of babies, and unfortunately a lot of deaths, as I remember—about a thousand a year Most of these were posted, and it was startling to see the almost uniform absence of meningitis on the postmortem table, as contrasted with the apparent frequency of meningitis in the wards It is a fact that is always recognized, but seems to be never quite comprehended that there is hardly a disease children have that will not produce the symptoms of meningitis I have seen all the principal signs of meningitis in acute follicular tonsillitis, in pneumonia and gastric trouble, and there is a whole group of cases of pseudo meningitis without apparent cause—a group the French call meningism In other words, I would say that pseudo meningitis is enormously more frequent than true meningitis Every little while I see a case of cerebral paralysis, for instance, in which a diagnosis of meningitis was made by the attending physician at the time of the attack, and held to for a considerable time subsequently Like Dr Brown and Dr Lyman, I not infrequently see cases of poliomyelitis that at the inception were very much like meningitis, and were so diagnosticated I do not mean, for a moment, to cast a shadow of doubt upon the diagnostic ability or medical acumen of the gentlemen quoted here this evening, but I would like to emphasize a caution that it is almost too easy to make a diagnosis of meningitis In the little consultation work that comes to me in this direction, I much more frequently have to say "No, I think it is not meningitis," than to say "I think it is" The symptoms of general toxemia arising from any sort of infectious disease in children are so prone to manifest themselves by cerebral symptoms, and if we have two or three or four striking cerebral symptoms and the patient is very low, it is so easy to say meningitis, when really there is no adequate foundation for such a diagnosis

Dr David O'Shea—Taking it for granted that Dr Brower's treatment for meningitis is now recognized as the most valuable treatment within our knowledge, there can be no doubt in my mind that Brower's treatment possesses very many advantages which are not possessed by others Lumbar puncture and Skeer's sign, with a good deal of experience, is a condition that will make a clear diagnosis of meningitis This method will certainly exclude pseudo meningitis diagnosis

Treatment is simple yet very effective, administered as follows Locally, after shaving the scalp, the following combination is applied Lanolin et iodoform, 10 per cent, three times, daily, ice continually in cap, dark room, plenty of fresh air, free bathing, diet milk, soups, icewater and fish General treatment potass iodid and ammo bro Local treatment as previously stated

The following cases consulted with Dr Brower

Case 1, in 1894, female aged 3 years, sick six weeks, recovery perfect

Case 2, in 1894, aged 3 years 6 months, sick nine weeks, perfect recovery

Case 3, in 1894, aged 4 years, sick seven weeks, fully recovered

Case 4, in 1894, male, 2 years of age, sick eight weeks, recovery perfect

Case 5, March and April, 1898, 1½ years of age, female, sick nine weeks, recovery perfect

Case 6, 1898, male, 3 years, sick seven weeks, recovery perfect

Case 7, 1898, female, 5½ years, sick seventy one days Hereditary tuberculosis This case broke my record I had all hopes of her recovery until the tuberculosis condition exhibited itself in miliary tuberculosis, complicated with acute nephritis Previous to Dr Brower's treatment my success was limited

Compared in percentage to the recoveries Brower's treatment, recoveries, 86% per cent Previous treatment digitalis and belladonna was my anchor sheet, but failed in percentage of recoveries In eight previous cases, 56 per cent of recoveries

To find the good effects of Brower's treatment, you will find iodid in the urine three hours after application I hope Dr Brower's success will continue

Dr D T Nelson—This discussion comes very close home to me, as I have had three cases in my family of what I called cerebro spinal meningitis Two died and one recovered The worst case got well The little girl was 1½ years old at the time of the attack, the whole duration of the disease was perhaps six weeks The baby was born nine days before the great Chicago fire She was seen by our best physicians I am not sure that Dr Lyman saw her, but the elder Davis and the elder Byford and Roler did, and like myself, they supposed she could not recover because it was tubercular meningitis To give an idea of the severity of the case, the child was ten days without winking, and as she recovered scales fell from her eyes I do not know whether it was simply dried mucus or whether they were portions of the cornea I supposed she would never see, but she sees as well today as any one She likewise hears as well as any one, and has had no nervous disturbance since except chorea at the age of 10 or 12 years She recovered completely from the chorea, she was loaded with strychnin until she fell down stairs, but whether the fall was due to the strychnia or the chorea I do not know Strychnia was pushed till there was rigidity of the muscles of the face and jaws Her mother said she should not take any more strychnia, and she did not, but she had considerable chronic symptoms afterward I am not familiar with the iodoform treatment, that has come up since I have had much to do with these cases There was one remedy, a sheet anchor in my day, in the treatment of these cases, and that was repeated blisters, as one healed it was repeated, and it did more to save lives than anything else in my belief, provided the patient could take nourishment I believe that was what saved this patient, she would take beef tea and milk, all that was given to her, and that was in large quantities The trouble was with respiration and the heart's action There was no trouble fortunately with deglutition The respiration was slow, it would stop entirely sometimes for minutes Once I went to the drug store to get a supply of medicine and they sent word that I need not bother about it as the child was dead, she had stopped breathing, they supposed so long that she must be dead, and with reason, except she did not become pale The child had received enormous doses, for her age, of digitalis and belladonna, and if any internal therapeutic agents saved the child it was these For external applications she had blisters

By the advice of William H Byford I once placed a blister on the forehead We believed the case to be tubercular meningitis, and therefore expected a girl of 12 to 14 years would die Our patient did die We should give as little morphin as possible I am a great believer in calomel I remember at that time I was consulting everybody, and one physician said, give diuretics, let your sheet anchor be diuretics, as potassium acetate, that is, if there is sufficient vitality in the nervous system to aid your remedies in producing their usual effect, if the system is not completely paralyzed by the disease, excretion is the desirable thing But the cases vary I remember in one of the early epidemics a leading dentist here died with what was believed to be cerebro spinal meningitis after an illness of thirty six hours I think we will always find that in the early cases of an epidemic the mortality is much greater than later, but it may vary from 100 per cent to almost nothing

One symptom has not been spoken of tonight, although it is recorded in the older books, namely, the spotted character of the skin, which was well marked in my severer cases

The first case I ever saw was in the army, soon after the surrender of General Lee, in the U S Post Hospital of Richmond, Va The disease was quite prevalent in the army at that time, and was called spotted fever The spots were well marked, as large as the finger nail and as small as a split pea, due doubtless to paralysis of the cutaneous vessels

To return to the blister it seems to me from a study of physiology in former years, that if one hand be put in ice water and a reduction of temperature be shown in the other, there is something of reflex action, though I see it decried now by many neurologists It seems to me a blister can and does have some effect Bromids and ergot were then used freely in the early stages of the disease, and later, when the evidences of effusion and paralysis appeared Iodid of potassium and diuretics were substituted, but blisters were continued until complete recovery took place

My little baby boy, who died at the age of four months, June, 1874, of cerebro spinal meningitis, in the stage of effusion, was the first case that I ever saw or heard of where the lateral ventricles were tapped by the Dieulafoy aspirator, which was then beginning to be used It was done by Dr H A Johnson at my earnest request, as he feared the child would die during the operation It was done through the anterior fontanelle, and about an ounce of serum removed, and while the baby rallied for a time, it died in some twenty four hours from the reaccumulation of the fluid. Although electricity was freely used, the child died from failure of respiration and of the heart's action

Dr **Archibald Church**—I am glad to be made familiar with the ocular sign in meningitis, and in the same connection I would like to call attention to the sign mentioned by nearly all writers on the subject, but which is rarely sought for in practice—the sign of Kernig It is due to the tendency to rigidity, and is elicited by straightening the leg upon the thigh flexed to a right angle with the trunk, as in the sitting posture In the great majority of cases a certain amount of contracture will be demonstrated in the flexors of the knee before nuchal retraction appears I have found this so constantly present that I look upon it as of extreme value

In a recent very comprehensive article by Councilman, published by the State Board of Health of Massachusetts, and based upon the examination of a large number of cases occurring in Boston during the past two years, the statement is positively made that in all of the epidemic forms of cerebro spinal meningitis the meningococcus of Weichselbaum was found He asserts that it is the essential organism in the epidemic form, and also suggests that a test of the nasal mucus in cases of epidemic meningitis will often lead to the detection of the meningococcus, thereby serving to establish the diagnosis A recent contribution in German literature, however, would give the negative to the assertion as far as the nasal secretion is concerned, because in a large number of cases where no meningitis was present, the meningococcus was found in the nasal secretions This, however, gives us an idea how infection occurs when the nasal vault or the internal ear is ruptured by fracture When Councilman presented his topic before the Johns Hopkins Hospital Medical Society, Welch, who had a large experience in the epidemic form from the material presented by Barker and Flexner, took the ground that very likely the meningococcus of Weichselbaum was one stage of the pneumococcus, which he had found invariably in the epidemic at Lanaconing He was not willing to assert this, but thought it might be the case

The relation of meningitis to pneumonia is one of great intimacy, as has been emphatically pointed out before this society by Dr Wells, and this table presents the same fact You will notice meningitis appeared to attain its greatest frequency in 1891 to 1894 and 1895, years when grippe was prevalent, and grippe, pneumonia and meningitis are almost interchangeable terms as we know from clinical experience Pneumococcus meningitis is almost invariably fatal, while the meningococcus form presents 15 to 50 per cent of recoveries If we can detect the micro organism we have a prognostic help Lumbar puncture, if giving positive findings, is of some value In a case under my care some years ago at St Luke's Hospital, lumbar puncture carefully performed several times was negative, at the same time the head was markedly distended It was an infant and the fontanelles were still open and bulging I subsequently punctured the lateral ventricle through the lateral angle of the fontanelle, and secured a large quantity of fluid which presented the pneumococcus in large numbers The child died, and a section made by Dr Eisendrath, showed that there was in addition a tuburcular meningitis—a rather rare mixed infection I think lumbar puncture should be carried out as a routine measure, and as a diagnostic measure has value, but as a therapeutic measure it is of slight importance Jacoby of New York has suggested making an opening into the ventricles through the skull and dura, in conjunction with lumbar puncture, for the purpose of washing out the intradural spaces By making such openings the entire field could be irrigated He also advises that iodoform be used in making the flushings I have used iodoform inunctions as recommended originally in Germany, in a number of cases, and like Dr Neal, have associated small doses of calomel I am indisposed to give up the calomel, feeling that it may act as a germicide, perhaps, or counteract in some way the toxic effects of the germ activity, besides increasing elimination through bowel and kidney

Dr D R **Brower**, in closing the discussion, said I am very pleased that this communication of mine should have produced such an interesting discussion I am very much obliged to you for the attention you have given it and I am very grateful that there is some disposition to investigate it and to induce further investigation I would not have dared to come to this Society and tell you that I knew of 46 cases of meningitis with 33 recoveries, I would have been annihilated if I had done so, but I brought with me the names of medical men who ought to know, if they do not, how to diagnose and investigate some of these cases I saw most of these cases but I will not father them all These observations began some ten or fifteen years ago I do not believe these cases were pseudo meningitis—I do not believe they were intestinal reflex irritation, I believe they were meningitis Dr Neal is sure his cases were meningitis and not pseudo meningitis The value of the therapeutic measure is the persistent use of 10 per cent inunctions of iodoform with lanolin to the shaved scalp, thoroughly applied, and in an hour we can find the iodoform in the urine or in the saliva The system is saturated with iodin and I believe that iodin is a germicide Calomel was given to most of these cases one time or another constipation characterized the majority of them, they vomited castor oil, and calomel had to be given as the agent that would produce a laxative and a diuretic effect

As to the Skeer sign, Dr Skeer, some fifteen years ago, first called my attention to this The first case he observed was a member of his own family who died of tubercular meningitis, and in another case occurring in his own family, the same sign was present and was verified postmortem He called my attention to this sign in a case I saw with him in consultation In that case the result was verified postmortem, and in two other cases in which this sign was present the result was verified in the same manner So I know of four cases in which this sign has been verified postmortem Of course that is not very many It is not present in all cases of tubercular meningitis If it is present in any other disease I have never seen it It is the first stage only of this sign that is easily diagnosed The reason I seldom see it in consultation is that I am never sent for until it is pretty nearly extinguished When the case is about to die the consultant is sent for in order that the case may go *secundem artem* I would suggest, as Dr Moyer has suggested, that there might be some positive investigations along this line and I hope the members of the Society will attempt to cure this disease by iodoform inunctions Use calomel all you please, and properly selected means of reducing temperature locally and generally, but give iodoform inunctions a trial and let us, a year hence give this subject further consideration I would be glad to have the members of the Society communicate their investigations I believe the Skeer sign is pathognomic of meningitis I do believe that some cases of acute meningitis are modified in their course, possibly aided to recovery by inunctions of iodoform and lanolin

San Francisco County Medical Society

Dr **Harry M. Sherman** presented a paper entitled

FAULTY UNION IN A FRACTURE OF THE FEMUR, RESECTION, AND UNION IN GOOD POSITION

The history of the case reported was as follows The patient, a young woman of 18 years and 10 months, had fallen when a child of 8 and struck on her hip since which time, or for over ten years she has had a limp, rendering locomotion almost impossible, and has suffered considerable pain The fall occurred during an epileptic seizure At that time she was confined to the bed for a week only, the trouble not being consid ered grave at first, it subsequently became worse She had not been able to stand on the right leg, the one affected by the fall, for ten years A few months ago she fell again, striking her knee, there resulted some soreness of the knee, but no trouble with the hip The patient, at the time she presented herself at the University of California clinic, was exceedingly fat, so much so as to prevent her from walking almost entirely, for she could only with great difficulty and for a short time use crutches On examination she exhibited 20 degrees of adduction, and the greater trochanter was 5 25 cm above Nelaton's line, owing to the excessive fat the diagnosis could not be exactly made out, but seemed to be a posterior dislocation of the head of the femur The possibility of an intracapsular fracture was discussed, but was not held to be very probable There had been no epileptic seizure for some years The right leg was flexed 40 degrees, and had the characteristic appearance of a posterior dislocation The girl was sent to the Children's Hospital, where it was decided to operate for the reduction of the dislocation An incision after the method of Lorenz was made, the proper muscles divided, and then, when the finger was introduced, the head of the femur was found to be in the acetabulum Forcible traction was made, resulting in a prompt fracture of the neck of the femur, at the site of the old fracture A gauze drain was introduced, the limb bandaged and fixed with some considerable abduction The operation was made August 14, and the patient was up October 20 Shortly after first getting up she had an epileptic attack and was placed upon bromid as an article of diet She was discharged from the hospital with instructions to use for two weeks, two crutches, for two weeks, two crutches in the street, and one in the house, for two weeks one crutch in the house and a crutch and a cane in the street, for two weeks a crutch in the street and a cane in the house for two weeks a cane in the street and nothing in the house, and after another two weeks to use no artificial support either in the house or out of doors At the end of three months the patient was again seen, and at that time she had a slight amount of adduction, but walked well without any assistance She was seen still later, and the result was very satisfactory There was considerable fibrous anchylosis, but little motion at the hip joint, yet she could walk well and had no pain Dr Sherman urged that operative interference be more often resorted to in those cases of intracapsular fracture of the neck of the femur which were not impacted, where there was impaction, interference was not needed, but he urged that many cases of this fracture in old people might be very markedly improved by operation somewhat after the method he had employed Dr Sherman also exhibited Grattan's osteoclast, recently devised for the more satisfactory refracture of bones He illustrated its manner of easy adaptation to almost any bone or region, and dwelt upon the fact that with this instrument it was possible to fracture the bone by means of what was practically a blow and not merely a crushing, consequently it gave a much cleaner fracture than could be obtained by other devices, and the fracture was always at a known point, opposite the descending jaw, or "jack," of the instrument He had that day used the instrument on two legs with eminently satisfactory result He also exhibited some photographs and skiagraphs of a case of arthritis deformans of both knee joints, which was remarkable for the amount of deformity, and the fact that apparently the man ought not to be able to walk with the amount and extent of deformity present The knees, especially the right, were so much disturbed in their relations that the inner tuberosity of the tibia was exactly over the external condyle of the femur Yet the man could walk easily and had very little limit to the proper motions of the joint He had applied to the University of California clinic for a brace to relieve the tendency of the leg to spring outward in walking, due to the improper location of the strain caused by the deformity

Dr Kenyon said that he recalled a case he had operated upon many years ago, for relief from the deformity resulting from a fracture of the femur He had operated by sawing through the femur between the greater and lesser trochanters, and the result had been excellent, the patient being some years afterward killed while she was riding horseback, thus showing that she had improved sufficiently to take such exercise

Dr Sherman said, in reply, that his case was one of intracapsular fracture, and that the operation had been an intracapsular fracture, and not a subtrochanteric osteotomy, as was the case with the patient reported by Dr Kenyon He urged that these cases of non impacted fracture be operated upon, being strongly of the opinion that the results would be very much better than at present if this was done

Dr Whitney said that he had recently seen two cases of intracapsular fracture of the neck of the femur, in both of which there had been crepitus and every evidence of non impaction, and yet both of the patients had refused to remain in bed, and had gotten up almost immediately after the accident Both were doing well and walking around with very little discomfort One was a woman 82, and the other a woman 85 years of age Certainly there would have been nothing gained in these cases by operating He asked what explanation Dr Sherman would make of the fact that these women were so soon walking about, apparently with a perfectly healed fracture of the neck of the femur, where there had been no impaction and no operation

Dr Sherman answered that he thought the patients mentioned were probably walking on the capsule, and that there had not been bony union of the fracture He did not believe that bony union ever occurred in cases of intracapsular fracture of the neck of the femur in old people It was a question entirely of the nourishment of the upper fragment, and the nourishment was so trifling, without impaction, that he did not believe it possible for true bony union to occur For that reason he was extremely careful in examining all cases of suspected fracture of this region, not to use any force, he never made the examination under chloroform, and never manipulated the leg at all forcibly If he could not easily determine the condition he much preferred to await developments rather than to use force and run the chance of breaking up an impacted fracture

Dr Nusbaum presented a report of a case of

CONGENITAL DEFORMITY

He had hoped to be able to present the case to the society, but, unfortunately, it had some days previously developed bronchitis which proved fatal very suddenly At birth the case presented the following appearance The right radius was absent, the hand was clubbed, the thumb, which was perfectly developed, hung by a mere thread from the hand, the right ear was bent forward, and in front of it was a tit of skin, sharply pointed, near the umbilicus were two hernias, there was right facial paralysis The child had been born on Jan 17, 1898 It was the fifteenth child of the parents, the father was a confirmed drunkard, the mother was apparently healthy, six of the fifteen children are living and all were normal at birth The birth of the present one was normal and no forceps were used The mother stated that she had fallen four times while carrying the child, and it was probable the husband had abused her during the period of gestation The husband had applied to the doctor during the pregnancy for some ergot, expressing his desire to produce an abortion, it was not supplied by Dr Nusbaum but the man may have obtained it from some other source The Doctor then cited a number of authors on the subject of multiple deformities, and stated several theories

Dr Hunkin said he did not think that external violence could have produced the deformities described, he was rather inclined to believe that the condition of the thumb and the absence of the radius might be explained by assuming an incomplete intra uterine amputation, from the cord having encircled the arm Dr Kerr asked if there were any rudiments of the radius and it was stated that there were no rudiments, that the radius was totally absent

Dr Kerr then said that he thought no pressure or external violence could have produced the trouble, nor yet that it could have been caused by uterine amputation, for in either of these cases there would have been some trace of the missing bones He mentioned some statements which he had seen in a medical journal, the writer of which he could not recall, which were to the effect that in a number of cases where these multiple deformities had occurred, alcoholism could be directly traced as the probable cause One case in particular was mentioned in which the conception had commenced when the father was quite intoxicated, other children by the same parents, but which had been conceived when the father was sober, did not show any deformities at all

Dr Hunkin mentioned several cases which he had seen, but in which the radius was missing from both arms, and not only from one, as in this case, he felt that alcoholism could be eliminated from the cases he mentioned

Dr Sherman stated that he thought the condition of the thumb was the result of an incomplete intra uterine amputation, as has been suggested, no matter what the cause of the other abnormalities might have been As to the statement that the radius was totally absent, that he thought could not have been made with absolute certainty unless the case had been skiagraphed, which had not been done in this case He did not believe it possible to be absolutely sure of the absence of any bone, without the aid of the X rays He mentioned several cases which he had had the good fortune to see, one of which was the child of apparently, perfectly healthy parents

Two children had been born, both of them normal and healthy, the parents were abstemious, the father not drinking at all, and he thought not even smoking Yet there had been many deformities in the third child It had been brought to him to see what could be done He refused to make any statements or attempts at treatment until the child had doubled in weight It was then again brought to him, and a careful examination revealed double club foot, double club hand, rachitic deformities, and a peculiar condition of the knees Both knees were much deformed, the tibia on both sides was riding upon the femur, and there was absence of patellæ, with hyper extension He applied constant traction, till the tibia was drawn down to a point where it just rested on the femur, no amount of strain would, however, cause it to descend into place The child had sickened somewhat in the hospital, and he had sent it away to the country, but would later on make further effort to improve the very unfortunate condition of affairs

Dr Nusbaum said, in closing, that he was quite sure that there was no radius in the case he had reported, several physicians saw the case, and they were all of the same opinion

Cincinnati Academy of Medicine

Regular Meeting, October 17, 1898

Dr Ricketts made a supplementary report to a case of "Ununited Fracture of the Middle Third of the Left Humerus," which he had first reported to the Academy in February, 1898 This fracture had been but one of numerous injuries, there being sustained at the same time both maxillary and Potts' fractures The case had been operated on when it was found that union was not taking place A long external incision was made, the ends of the bone freshened and brought in apposition with a single piece of silver wire Unfortunately, erysipelas set in and involved not only the wound of incision, but spread over the arm, shoulder, chest and back, neck and face, and downward involving the buttocks Two months afterward his fracture was still not united The arm was not put in any kind of casing Whether the effect of erysipelas causing great irritation about the non united pieces, or what not, at any rate when he began to recover from the debilitating effects of his erysipelas, the ends of the bone began to knit, and now he has almost perfect use of the arm with but a minimum of shortening The Doctor, in investigating the source of the erysipelatous attack, found that the patient himself had had the disease but a few months previously It is interesting to note that previous to the operation the patient had but little or no use of his forearm and fingers It was found during the operation that the median nerve had been caught between the fragments and more or less lacerated Release of the nerve was eventually followed by perfect use of the muscles supplied by it The man is 58 years of age

The second case reported by Dr Ricketts was one of epithelioma of the nose, almost centrally situated He had burned away the diseased portions with a caustic paste, and had performed a plastic operation, pushing the flaps from the cheeks and using the septum nasi as a sort of beam for their support This was three years ago, and while during that period he had been compelled several times to remove recurring nodules, the present result may be looked upon almost as a cure

Dr Robert Sattler reported two cases of myopia of high degree In one, a young woman, the exact degree could not be exactly determined, owing, probably, to dioptric as well as axial astigmatism The best vision obtainable was 2/10 Treating each eye separately, he first established a traumatic cataract, removed the lens, and by a number of discissions established a clear pupil Fourteen operations were made in all Now with slightly plus glasses she is able to read the finest print. In the other case, a young man, the myopia of each eye amounted to sixteen diopters Only one eye has as yet been touched, and a traumatic cataract is very evident The Doctor expects by removal of the lenses to take away from nine to twelve diopters from the myopia, so that the boy with a concave glass of from seven to four diopters may have fairly good vision

Dr Sattler then read the regular paper of the evening, entitled "Recent Advances in Ophthalmology of Interest to the General Practitioner" He first called attention to the modern hope of restoring comparatively good sight in patients afflicted with high grade myopia, not rapidly progressive, nor connected with serious damage to important structures as liquefaction of the vitreous and detachment of the retina The case he exhibited was but one of a large number both in his own and in the experience of others The method was first the formation of an artificial cataract by means of carefully guarded traumatism, the removal of the cataract thus formed, followed by discissions in sufficient number to establish a useful pupil, or the removal of the non cataractous lens —an operation attended with slightly increased danger

He then took up the subject of senile cataract, and the actions of the numerous charlatans who advertise its removal without the use of the knife, their method consisting in instilling into the eye a collyrium of any mild combination, usually with boracic acid, and following this up with massage which massage could only be administered by the advertiser himself The relief—never cure—occasionally obtained, the speaker ascribed either to the imagination of the patient, or to the lenticular myopia sometimes occurring in old age, presenting the well known phenomena of second sight Complete relief from any lenticular opacity could not be brought about without operative procedures

The third point to which he called attention was the care of the new born infant's eyes as a prophylactic to blenorrhea neonatorum He recommended that in all hospitals and public institutions, among the lower classes of society, and in all infants in whom a possible infection was even suspected, there should be immediate disinfection of the conjunctival sac according to the method of Credé the careful and proper use of a 2 per cent. solution of nitrate of silver, not dropped into the eyes, but with the child's head between the obstetrician's knees, with proper cleanliness especially of the hands, with the lids everted, a thorough brushing to be made, followed by the washing away of the excess of silver solution with sterilized water If the silver solution were merely dropped into the eye, a severe traumatism of the cornea might result, which might be followed by the direst consequences He also stated that while specific gonorrheal infections were undoubtedly the most virulent, any purulent ophthalmia at this very early period of life would probably result seriously as far as ultimate vision was concerned

Discussion was by Drs Christian, Caldwell, Johnston, Jones, H M Brown, J Louis Brown, Judkins and the essayist

PRACTICAL NOTES

Ichthyol in Variola —A writer in the *St Petersburg Med Woch* of August 20, extols his remarkable success in variola with 20 per cent ichthyolized collodium, which he had found very effective in herpes zoster

Mentholised Iodol —The addition of 1 per cent menthol to iodol disguises the odor while enhancing the therapeutic effect in nasal and laryngeal troubles —*Klin Therap Woch*, September 25

Helmerich's Salve New Formula —Triturated sulphur 10 gm, potassium carbonate, 5 gm, aq dest, 5 gm, vaselin 40 gm Dissolve the salt in the water, heated, add the sulphur and vaselin and stir in a warm mortar until cold —*Jour de Méd de Paris*, September 18

Dry Bismuth for Burns —This is recommended by Lassar as the most effective of all dressings Bardeleben prepares "bismuth burn badges" which insure a painless and reactionless healing in nearly every case —*Dermatol Ztschft*, iv, 4, in *N Y Med Monatsheft*

White of Egg for Inflammations —Lewith asserts that fresh white of egg applied with the finger soon dries into a protecting and contracting membranous shield under which itching subsides and inflammations heal —*N Y Med Monatsheft*, August

Amyl Nitrate in Post Hemorrhagic Anemia —Bompiani of Rome has obtained remarkable results with inhalations of amyl nitrite in cases of acute anemia consecutive to extensive hemorrhage, and recommends it as superior to the subcutaneous injection of ether in reviving persons in danger of death from hemorrhage —*Journ de Méd de Paris*, September 18

The Sources of Hematuria —Dr David Stuart (London *Lancet*, July 2, 1898) classifies renal diseases with reference to hematuria, as follows 1, traumatismal, *a*, injury, *b*, calculus, 2, passive hyperemia, *a*, pressure on renal veins, *b*, torsion of the same, *c*, reflex spasm of arterioles, 3, inflammatory hyperemia, *a*, nephritis, acute and chronic, *b*, tuberculous disease, *c*, cystic degeneration and hydatids, 4, tumors of the kidneys

Curare in Epilepsy —Inject, every five days, one third of the following solution curare 50 cm , aq dest 5 gm , hydrochloric acid 1 drop Let it stand twenty four hours and filter The injection is not painful, does not produce any reflex symptoms and has never caused the slightest indication of intoxication —*Jour de Méd de Paris*, September 18

Absorbing Power of Potassium Iodid —In cataract operations large doses, 3, 5 to 10 gm a day, must be administered, and the remains of the lens will be rapidly absorbed, rendering a second operation unnecessary In operations for myopia a small discission opening is all that is necessary with the potassium iodid, thus preventing irritation of the uveal tract by masses of lens substance —*Klin Therap Woch* , September 25

Orthoform in Intramuscular Injections —Loeb adds 5 to 10 per cent orthoform to his injections of 10 per cent hydrarg salicylicum and paraffin, and finds that it prevents the local pain from the injections for eight to ten hours He first tested the intramuscular injections of 10 per cent orthoform with paraffin on himself, and established its efficacy and harmlessness The medicinal injections were absorbed as readily as without the orthoform —*Klin Therap Woch* , September 11

Hot Water in Hemorrhage —Hot water injections have been found effective not only in gastric hemorrhage, but hemorrhages from the nose and lungs Two or three injections a day with water at 45 to 50 degrees C , have arrested cases that had resisted all other treatment One is described in the *Klin Therap Woch* of September 18, a woman with commencing tuberculosis, whose severe hemoptysis had persisted for days, but yielded in one day to the injections

Menthol in Anthrax —Braun has found 2 per cent alcohol solutions of menthol very effective in anthrax, curing it in much less time than usual He applies it on a gauze strip, with which he packs the main cavity, after it has been cleaned out with cotton, and covers with an air tight covering and compressing bandage, left for twenty-four to forty eight hours The application is slightly painful at first —*Klin Therap Woch* , September 18

Aseptic Tamponade of the Uterus —A large funnel shaped speculum is introduced into the vagina, and the anterior cervical lip is seized with a pair of ball forceps, provided with a hook on ach side, and drawn down until one hook rests on the edge of he speculum The posterior lip is seized in the same way and ooked on the other blade of the speculum The tamponade hen proceeds as usual , the operator has both hands free, and he gauze does not come in contact with the external genitals, while he can visually inspect the whole process —From Wyder's clinic, Zurich, *Munich Med Woch* , September 20

For Subconjunctival Injections —Take metallic iodin 1 to 2 cgm , potassium iodid 1 gm , boiled distilled water 30 gm Inject 4 or 5 drops of this solution under the bulbar conjunctiva every two or three days increasing progressively to 10 or 15 drops These injections are comparatively very slightly painful, but cause a light transient chemosis The favorable effect of the treatment becomes evident in the course of two or three weeks, as the size of the floating bodies diminishes and the scotoma improves, as does also the central visual acuity, even in cases of macular choroiditis —*Semaine Méd* , September 28

Raising Paralyzed Eyelid —J Hirschberg (*Deutsche Med Woch* , September 28) describes his success with the Birnbacher operation in five cases of pistol shot in the temporal region, causing paralysis of the eyelid on that side, although the sight was retained in some cases No narcosis is required , the upper edge of the superior tarsal is exposed by a perpendicular incision, and three double strong silk threads are passed through it and then under the skin to above the eyebrow, where they are tied tight over drain tubes The free edges of the lids are temporarily sutured together lightly to prevent irritation of the cornea by the lashes In three or four days the eyelid can be raised and closed at will, as the muscular power of the non paralyzed muscles is transmitted to the paralyzed lid

Tests for the Hearing —Ostino asserts that a deficient perception of the spoken letter "S," in comparison with our consonants, indicates otitis of the internal ear, the more decidedly as the formula for the distance of perception of the other letters is inverted If in addition "C" and "G" are also deficient, it indicates that the disturbance is not limited to the scale "do, do," but affects also the middle scale Diminished perception of consonants spoken in a bass tone indicates alterations in the apparatus for the transmission of sounds In affections of the internal ear there are islands of deficient perception limited to one consonant, but in affections of the middle ear, the deficient perception extends contemporaneously to several consonants of varying height and tonality, but all comprised in the lower limits of the tone scale A deficient perception of the letter "F" is an almost constant indication of acute otitis of the middle ear, simple or with effusion, with or without perforation Beyond the maximum limit for the perception of a consonant, it is confounded with another consonant, usually one of the same tone height as the first —*Gazzetta degli Osp e delle Clin* , September 18

Treatment of Pulmonary Gangrene —This treatment is founded on antisepsis (editorial in *Journal de Méd de Paris*, September 18) The patient should be placed in a large room and the air disinfected with phenicated spray To disinfect the lungs, give one of the following potions in teaspoonfuls during the twenty four hours No 1, alcoholatum eucalypti 2 gms, julep with syrup of poppies (julep diacodé) 120 gms Or No 2, Labarraque's solution 4 gms , sodium hyposulphite 4 gms , julep 120 gms Antiseptic inhalations are also useful phenic acid 50 gms , water 950 gms Put in a bottle and inhale the vapors Trousseau recommends essence of turpentin Pour a few teaspoonfuls of the spirits in hot water and inhale Jaccoud recommends for internal antisepsis 50 cgms salicylic acid during the day Tonics of all kinds should be used *larga manu*, with digitalis and caffein when collapse threatens If there are several foci, medical treatment is all that is possible, but if the gangrene is circumscribed and this treatment is ineffectual, pneumotomy and drainage are indicated The part of the lung involved has been resected in some cases with satisfactory results

Sattler's Operation for Myopia —This operation has been performed on thirty patients to date, and has proved more than satisfactory , the operative astigmatism is very slight as a rule , the eye heals much more rapidly than with other methods and without the least inflammation, in nearly every case , and only two interventions are required He first makes an incision 5 to 7 mm in length, perpendicular to the vertical meridian and about 1 5 mm from the edge of the cornea, with a Weber hollow lancet The anterior capsule is then seized with a sharp hook and the lens substance loosened at the equator and from the posterior capsule A Daviel spoon is then pushed a little way into the front chamber, slightly pressing down the upper lip of the wound, while another Daviel spoon is applied to the region of the lower edge of the cornea in a horizontal position with a moderate pressure backward By this maneuver the entire nucleus is evacuated and the process is repeated a second or third time, as long as it brings lens substance without difficulty The iris is then replaced and one drop of atropin instilled The amount of the lens substance thus evacuated amounts to two thirds or even three fourths of the entire lens In some cases this intervention is sufficient, but usually discission of the posterior capsule is required later He has recently applied this same operation to nine cases of lamellar cataract with perfect success —*Klin Therap Woch* , September 18

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE INCLUDING POSTAGE

Per Annum in Advance	$5 00
Foreign Postage	2 00
Single Copies	10 Cents

In requesting change of address give old as well as new location

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
No 61 Market Street (Occidental Bldgs), Chicago Illinois

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association Dr Henry P Newman 100 Washington St Chicago Ill sending him a certificate or statement that the applicant is in good standing in his own Society signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character intended for publication in the JOURNAL should be addressed to the *Editor* and all communications relative to the business of the JOURNAL proof sheet returned or in regard to subscriptions should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL

SATURDAY, OCTOBER 29, 1898

AGAIN THE BICYCLE

At more or less regular intervals the medical journals discuss the use and abuse of the bicycle That the latter is a valuable aid as a promoter and restorer to health the active partisanship of the bicycle world will testify, regardless of any and every attack made by physicians Like every other therapeutic resource, it should not be applied indiscriminately to all cases, such a course would soon establish an abuse No one would advise a patient afflicted with organic heart disease to become a professional "scorcher," or to exercise to the extent of a fifty- or a hundred-mile run, any more than he would countenance a hundred-yard dash as a daily exercise, yet we can easily see how an easy ride of five or ten miles or a walk of the same distance would be of great advantage to such a patient Every individual is a law unto himself Where one would look upon a century run as but a pleasant bit of exercise, another, in apparently equal physical health and with the same training, would be incapacitated for several days by such an effort

A number of years ago, before cycling attained its present popularity, medical writers warmly discussed the terrible results this sport would have upon the female pelvis, especially as regards child-bearing The manufacturers quickly took advantage of this state of affairs, and reaped the rewards of their industry in the sale of various patterns of sanitary saddles so-called We are not aware that the obstetricians are having any greater difficulty in delivery than formerly possibly it is due to these very saddles, possibly not The heart was the next to claim the attention of the bicycle enemy We read the dogmatic statements of a medical brother that no one with organic heart disease should ride a wheel, we were impressed with his reasoning and nodded sympathetically as we perused his doughty arguments, and we turned contemplatively the pages of the JOURNAL and were soon absorbed in Professor A 's article on "The Use of the Bicycle in Organic Heart Disease", and perhaps as we glanced out of the window we observed that infatuated Dr B , with his aortic incompetency, wheel smilingly by as he makes his rounds, happily unconscious of his deadly peril And now it is the kidney and it must be confessed that there is evidence of a more tangible character here MUELLER (*Munchener med Woch* , 48, 1896) reports his observations on the urine of twelve cyclists, eight of whom were in training and the remaining four not Their rides were from one and a half to three hours at an average rate of speed Examination before the ride showed the urine free from albumin in all instances save one—a professional Seven of the eight in training showed a marked albuminuria after the ride, six of the eight, including the one whose urine contained no albumin, showed large numbers of casts for the most part of the hyaline variety, and a few white-blood corpuscles. Of the four untrained cyclists, two developed albuminuria and a third the presence of cylindroids after their ride In all these cases these rather alarming symptoms disappeared in a few days, leaving no trace "Leaving no trace," and if there is one thing that pathologists have endeavored to impress upon the profession, it is that a chronic irritation will eventually result in the evolution of new-formed connective tissue, and again that new formed connective tissue in whatever part of the body it may be found, will in time undergo cicatricial contraction, in the kidney this would mean a condition of chronic interstitial nephritis The above cases were taken at random, and probably correctly reflect the urinary phenomena of a large majority of cyclists Your enthusiastic wheelman rides every day that he has a possible excuse for so doing in other words, he produces a condition of chronic congestion in his kidneys that is practically constant for as MUELLER says, several days elapse before the alarming urinary symptoms entirely disappear Is this condition any less dangerous than that chronic congestion produced by the ingestion of alcohol? Surely the decryer of the bicycle would have enough to rave against were he to leave the heart alone and turn his attention solely to the kidneys Nevertheless the bicycle will survive

THE DOCTOR IN THE SCHOOLROOM

In these doleful days of overcrowding and hospitalism it ought to be welcome news that a new field is opening up for our professional activity To the prophetic vision of the Cassandras of both sexes in our ranks—and they are many—the direful prospect has already presented itself of the day when disease having become extinct through the noble but suicidal efforts of the doctor and sanitarian, our occupation, like Othello's, will be gone Any new outlet for our energies will help to either postpone that *dies iræ* or to mitigate its horrors when it does arrive And we wish to seriously call the attention of the profession to the fact that there is opening up before us today in the schoolroom an almost entirely new field of usefulness, one which could profitably absorb the entire energies of one-third of our present membership and whose possible extent and usefulness to the community are alike well-nigh unlimited

Within the past fifteen or twenty years there has come a change in educational ideals and methods which amounts almost to a revelation Up to that time the wheels of the educational machine had been placidly revolving in the comfortable ancient rut of the belief that education was solely a matter of the mind, of the intellect, regardless of the body That this intellect aforesaid could be trained and increased in power and grasp simply by putting it through a divinely-ordained course of stereotyped mental gymnastics The chief problem was how to make the young idea acquire a certain standard number of mind tricks by a certain age All that was required of the body was that it should not interfere with the progress of the course, by breaking down or going to sleep To avoid these undesirable contingencies it had to be considered and even humored a little occasionally, but officially recognized, never It was by nature opposed on principle to the entire process and must be rigidly disciplined with an iron hand to submit to it True, the course of necessity extended over some ten or fifteen years of the child's life, and during that period the body grew and developed in a most remarkable way, but that was a mere coincidence, the mental growth was all due to the scholastic drill Time spent on training the body was simply time wasted, the mind alone was worthy of attention

Now all this is wonderfully changed, although the old error dies hard and still holds much of the field It is becoming recognized that the mind has an inevitable natural tendency to grow and to follow certain laws of development just like the body, that the extent of this development can not be altered or added to by "taking thought" much more than the "stature," that this growth proceeds on absolutely parallel lines with that of the body and for the most part *pari passu* with it that whatever hinders the healthy development of the body hinders or impairs the growth of the mind, whatever promotes the one favors the other

A new science has been added to the teacher's "requirements"—Child-Study The idea has at last dawned that education was made for man and not man for education that the system should be made to fit the child, not the child the system, as hitherto Hence the burning question of the day is, "What is the child?' "What is the natural history of the young human animal?" And the only man in the community at all competent to answer that question is the family physician And even he needs much training before he can safely be accepted as an authority upon the subject He has a good fundamental training, and his knowledge of the subject, both scientific and personal (practical), is fairly extensive, but it needs classifying, systematizing and testing by abundant actual experiment in the schoolroom The relations between the teacher and the doctor have not been at all as intimate as they should be nor the feeling as cordial Both have exhibited too much of that clerical spirit which HUXLEY describes so pithily as "that frame of mind engendered by much speaking without fear of reply" The doctor has been too ready to denounce what he can see to be the hurtful absurdities of the teacher's Chinese worship of ancient method without a proper appreciation of the practical difficulties of the problem of the teacher's position He is between the devil of the doctor and the deep sea of the proud and *exigeant* parent, who raises a "yellow roar" if his young hopeful does not know his seven times seven at eight and his capitals of Europe at nine precisely

Hence we must not be surprised if the teacher resents our criticisms, however well meant, and is inclined to regard us as a sort of perpetual opposition, only too anxious to advise the anxious mother to take her delicate child out of school, when the real cause of the "break down" has been parties and pie

The child is little, physically, but it takes at least four people to understand him, the doctor, the teacher and *both* parents And the time has now fully come when the doctor's contribution to this science should be prepared and made available for use in the great new educational advance The parent has full confidence in us, and the teacher is beginning to lean toward us, though slowly and half reluctantly, and if we but respond as we should, there is opening out before us one of the noblest fields of usefulness to the race that we can conceive of What, then, are the questions upon the solution of which our assistance is beginning to be demanded? They are many and hard and will increase in number and difficulty, but they fall into three great groups The first group concerns the hygiene of study and of the school, the school-room and building itself, the playground, the hours of study, of meals, of recreation The second group concerns the physical fitness of the child for study, his eye sight, hearing, muscle-balance, digestion, sleep, powers of resisting fatigue at different ages, periods and sexes The third relate to the most fundamental and fruitful question of all What is the child, what are his interests, his needs at successive ages, what course does he naturally follow in his development? We are beginning to trust instinct and nature even in the school-room In response to the first group of questions we can return fairly positive answers, for enough careful work upon the problems of school-sanitation has already been done by certain members of our craft to render the principles of the science and art fairly clear and definite But to reduce them to practice in a given building is a problem worthy of our best ingenuity And it is amazing how many of them are utterly disregarded even in our modern buildings Sufficient desk-space for a given number of children in rooms that look fairly light is secured, and then the vital questions of the plumbing, ventilating and heating are solved by letting them to "any reliable" firm making the lowest bid or having the most plausible or persistent representative Perhaps a land-surveyor known as the "city engineer" may be consulted or a busy doctor asked for an off-hand opinion, but usually the united ignorance of the school-board regards itself as fully competent to decide A committee appointed to investigate the public school buildings of one of our most progressive large cities reported over half of them defective and a fourth of them disgraceful There ought to be a physician on every school board and in every town of more than two thousand inhabitants, as school physician, with salary enough to enable him to devote a substantial share of his time to the study and remedy of these conditions Nor is this merely one of the "ought to bes" of the Utopian future In Boston there are already four physicians who, we believe, devote their entire time to this invaluable work and our most prominent educators are declaring that school-hygiene is to be the burning question of the coming quarter century The matter is being taken up in teachers' conventions, " normals " and summer-schools all over the country The conviction has been brought home to teachers by practical experience that to get the best work out of a class of children you must place them under the most favorable hygienic conditions possible They are taught that unless the air be fresh and the room cool, little can be expected of the pupil in the way of either attention or industry The better class of teachers everywhere are, as a rule, keenly alive to the defects of their rooms and eagerly anxious for competent advice and assistance to remedy them A daily visit from and consultation with a medical inspector would be welcomed by them A proper adjustment of window-space to floor, of cubic air-space to each child, of the desks to the direction of the light, of the height, slope and "hang" of the ventilation and heat-supply, would make a wonderful difference in the effectiveness of any building as an educational appliance Then would come the consideration of the play-ground This has grown up hitherto as a sort of accidental adjunct to the school-building and in many cases seems to be regarded as a necessary evil, which may be reduced to its lowest possible terms with impunity All that seems to be considered essential now is enough open space about the building to give it sufficient light, so that its shape and size are those of a narrow "halo" for the former The school house monopolizes two-thirds of the spaces leaving only a tiny plat in front, a narrow strip at the sides and a larger plat behind The lot is bought to fit the building, and whatever ground happens to be left over is turned into a play-ground Now, this is all wrong, for the play ground is as necessary and important a part of a good school as the building The educational and hygienic value of a play-space is enormous For ourselves, if we were compelled to choose between a school-house without any play-ground and a play-ground without any school-house, we would prefer the latter A certain area per child ought to be provided just as much as a certain cubic air-space of house room At least a fourth, if not a third, of the building fund ought to be spent upon the grounds A liberal space ought to be roofed with glass so as to be available in wet or stormy weather But what recognition of its importance do we find? Little or none Not content with reducing it to a mere border around the building and fag end of the lot, we choose the best part of the ground to put the building on We have seen a building containing four hundred children and its only play-ground the rear half of the lot, which sloped so abruptly down into a ravine that neither gravel nor sand would lie on its surface Worse yet, with a positive refinement of idiocy, if the remnant of the lot happens to lie in front of the house it is delicately laid down in turf, planted with ornamental shrubs and decorated with signs, "Keep off the Grass"! which ought to be supplemented by placards, "Go Play in the Gutter"! Grass and geraniums are evidently "of more value than many children "

THE DEPOPULATION OF ONTARIO

The question that has been troubling the French sociologists for the past few years—the low and decreasing birth-rate in their country—is now also becoming a living one with our neighbors over our northern borders, and it would appear with even greater show of reason If a birth rate of only 22 to the 1000 should give concern to the French statesmen and physicians, the still lower one of only 20 7 in the Province of Ontario ought, it would seem, to excite still livelier apprehensions for the future of a country that is thus failing in the very source of power, the production of an active and aggressive population The problem is made the more serious by the reverse condition existing in the adjoining Province of Quebec, where a very high birth-rate has long existed in what some would claim is in many respects an alien and inferior race The result is that, as in some parts of New England, the French Canadian is crowding out the Anglo Saxon in certain regions, and fear is expressed that unless some reversal of present tendencies occurs, all of Eastern Canada will become thus transformed The matter has been the subject of extensive discussion by the Canadian press, has been seriously considered in at least one convention of a prominent religious body, and will, it seems probable, give still more disquiet to the minds of Canadian publicists and patriots before any final satisfactory facts or conclusions are developed

As we have said before in this JOURNAL, the question is more a sociologic than a medical one, and yet it has its medical side, and there are many points of view from which it may be of interest to us as physicians In Ontario the people are, as in France, moderately prosperous, thrifty and forehanded, and in addition to this they annually lose, as in New England, a considerable proportion of their most virile and energetic element by emigration These are exactly the conditions that might be supposed to tend to a restriction of the birth-rate, the conditions favoring the existence of an aggressive proletariat are lacking In Quebec, on the other hand, the latter are directly favored by the influence of the Government and the church, as well as by the racial character and social state of the population, which has not been modified as in France, by military and political changes during the past hundred years In this province we have still the Frenchman of the seventeenth or eighteenth centuries, but living under vastly more favorable conditions, not the French peasant or citizen of today with his burdens of militarism and his non-prolific tendencies

It has been often charged, especially by some social alarmists among the clergy and elsewhere, who support themselves by the statements of a few medical writers, that amongst the Protestant population of the eastern border of our continent certain very reprehensible practices are commonly resorted to to check the increase of families, such as actual criminal abortion and other illegitimate methods That any wholesale charges of this kind are likely to be unjust ought not to require argument A population losing permanently its more vigorous male population by emigration is likely to have its birth-rate reduced When the late marriages, and the enforced spinsterhood of an undue proportion of the female population are also considered, the case is rendered still clearer The French Canadians, on the other hand, emigrate to return or take their women with them, their ideals of living are not so high and they marry early, and are probably not specially influenced by considerations of prudence in such matters, while, as already said, they have the direct encouragement of the provincial government, which, it is stated, offers a bounty for large families, and the active sanction of the church If other proof were wanting of the more direct dependence of the birth-rate upon social and political conditions than upon racial or physiologic peculiarities, the comparison in this regard between the Gallic race in Canada and in its native France at the present time would alone be sufficient There is, it is true a physiologic side to the question, it is well known that high feeding diminishes reproductive capacity in animals, and it is more than merely probable that the same law applies to the human species The more luxurious, or even the more comfortable we make a people in their living or diet, the less their fecundity

There is still another feature of the problem that is worthy of attention in a medical point of view A high birth-rate generally implies also an augmented death-rate, especially in the earlier periods of life This is seen in the slums of our cities, and everywhere by the general practitioner, who finds the greatest infant mortality in the class that is most productive in this respect Were this not the case, the question of population would be a more serious one than it is at present, but the fact implies a great waste of human life It has been calculated that if only one woman in six should do what she was well able to in the way of producing children, the population of the earth could be easily maintained The rest is a simple arithmetical problem—if four, five or six women out of the six are to do likewise, nature must interfere with some provision to keep down population, and this is generally effected to a large extent by increased infant mortality At the present time France, with the lowest birth-rate in Europe, has also the smallest death-rate while in some parts of Russia exactly the reverse conditions prevail

The low Ontario birth-rate, however we may view it, is nevertheless a misfortune to Canada, the greater since, unlike the somewhat similar state of affairs in some of the New England States, the country as a whole does not profit by her emigrants They come over the border very largely, to add to the wealth and population of the United States and, Canada is the loser In any way it can be considered, it is a matter worthy of the close attention of Canadian statesmen and patriots

CEREBRAL TETANUS

Tetanus has always been regarded as a nervous disease, but it is only since the discovery of the tetanus toxin that one could say precisely that the disease is due to a poisoning of certain nervous cells The affinity between nervous cells and tetanic toxin is shown very well in the following experiment of KNORR, inspired by WASSERMANN and TAKAKI[1] The cerebral substance of a guinea-pig is emulsified and mixed with tetanus toxin, and this mixture is then centrifugalized Two layers form at the bottom, the nervous matter, above this an opaque fluid In well-made mixtures it will be found that the fluid thus separated does not contain any poison, which has been fixed to the nervous tissue after the manner of a coloring matter This tangible reaction which occurs in the test-tube also occurs in the organism The tetanus toxin injected subcutaneously in an extremity of a guinea-pig becomes fixed by the cells of the spinal cord after a certain time when characteristic contractions appear, part of the poison reaching the cord by way of the nerves, another part by way of the circulating blood

---

[1] Münich med Wochenschrift, 1898, No 12

This specific affinity of nervous elements for the toxin is also shown when one injects the toxin into the brain of a rabbit In this way is produced a characteristic disease, namely, cerebral tetanus, which has recently been studied by ROUX and BORREL [2] This fact alone overthrows the opinion of WASSERMANN,[3] that there exists an antitoxin in the normal brain The poison adheres so strongly to the nervous material with which it is mechanically mixed, that when introduced into the subcutaneous tissue of animals it is not diffused, but is taken up and digested by phagocytes

The immediate fixation of tetanus toxin by nerve-cells renders it possible to limit the action of the toxin to certain groups of cells Thus when toxin is injected into the brain of the rabbit or the guinea-pig, there develops as shown by ROUX and BORREL, a disease characterized by intermittent convulsions, motor paralysis and polyuria, together with characteristic psychic disturbances The injection of five times as much sterilized water or physiologic salt solution in the same manner as a small amount of toxin does not produce any symptoms, hence the results can not be ascribed to mechanic injury

Eight to twelve hours after the injection the animal becomes restless, turns its head from side to side, runs around in the cage Abundant urine is secreted epileptiform convulsions come on, either simultaneously or on slight excitation The animal grinds its teeth and the wires of the cage, at the same time the hind legs may become paretic Intermissions in these symptoms often occur One-tenth c c may kill the animal in from twelve to twenty hours, smaller doses give rise to an affection lasting from three to eight or more days still smaller doses of toxin cause a tetanic affection, with emaciation, from which recovery may take place It is possible to inject the toxin into various parts of the brain with marked differences in the symptoms produced, and thus there is furnished a novel method of studying the functions of the various regions of the brain that may be of interest from a physiologic standpoint

The rabbit is much more resistant to tetanus toxin when it is introduced under the skin into the blood than when it is introduced into the brain The guinea-pig resists the intracerebral injection somewhat better than the rabbit, but the cerebral tetanus of the guinea-pig is as characteristic as that of the rabbit In the rat the symptoms of cerebral tetanus are markedly psychic The animal appears to be subjected to sudden attacks of great fear, and frequently it acts as though it were under the influence of certain delusions or hallucinations

An animal which receives antitetanic serum acquires a so-called passive immunity and withstands many times the fatal dose of tetanus ROUX and BORREL made the following experiments They injected large doses of antitetanic serum subcutaneously into rabbits Twenty four hours afterward 1 c c of tetanic toxin was injected into the brain, and all the animals died with typic cerebral symptoms in from forty-eight hours to six days later And yet the blood of these animals contained antitoxins One drop of the blood of an immunized rabbit mixed with the tetanus poison rendered the mixture inoffensive, when introduced into the brain of a new rabbit The extravasation of a small amount of blood during the intracerebral injections of immunized animals may neutralize the toxin and prevent the appearance of cerebral tetanus In guinea-pigs, therefore, similar experiments often failed to produce the desired result, because their brain is more vascular than that of the rabbit and less susceptible to the tetanus toxin

All these facts can also be demonstrated to be true as to the diphtheria toxin, which is more rapidly fatal when inserted into the brain than under the skin Immunized animals resisting enormous doses of toxin given subcutaneously perish when a small quantity is introduced into the brain The symptoms are more exclusively nervous, and at the autopsy one does not find any of the characteristic lesions of diphtheria intoxication, as for instance, congestion of the suprarenal capsules, because all the other organs have been protected by the antitoxin except the nerve cells Hence it is very evident that the nerve-cells have not the same affinity by any means for the antitoxin as for the toxin This is probably the reason why, in the prevention of tetanus, antitoxin serum so often fails, because when the antitoxin is used a part of the toxin has already become fixed to the nerve cells The antitoxin may neutralize the poison which is still circulating, but does not reach that which is fixed by the cells of the brain or spinal cord

Further experiments by ROUX and BORREL show that a few drops of antitetanic serum injected into the brain have a much better effect in tetanus of animals than large quantities of antitoxin introduced into the blood or under the skin Intracerebral injection does not save all the tetanized animals It must be injected before a certain length of time has elapsed after the poisoning Before recommending this method of administering antitoxin in human tetanus ROUX and BORREL insist that it will be necessary to extend the experiments to various species of animals, because it may be that in the horse and sheep for instance, as well as in man, the results

Annales de l Institut Pasteur 1898 No 4

[3] Berlin klin Wochenschrift 1898 No 1

would be different from those observed in guinea-pigs and rabbits

As already stated, rabbits and guinea-pigs passively immunized suffer from cerebral tetanus when the toxin is injected into the brain The question arises *Is this also the case in animals whose immunity is active?* This question is very pertinent, because many observers have advanced the opinion that antitoxin is elaborated by the cells which are susceptible to the toxin, that each symptom which is influenced by the toxin responds by producing antitoxin Two rabbits immunized against tetanus, and possessing an antitoxic serum, were found to be insusceptible to subcutaneous injection of 12 c c of tetanus toxin, which was fatal in a dose of 2 c c in the case of a susceptible rabbit One-tenth c c of toxin was introduced into the brain of the immune rabbits at the same time as into a normal control animal On the following day all the rabbits presented signs of cerebral tetanus The control animal died during the course of the day, the immunized animals died with typic symptoms, one after seventeen days, the other after twenty days These experiments demonstrate that the nerve-cells of an actively immune rabbit are sensitive to the toxin and that it becomes very difficult to understand how these nerve cells could prepare an antitoxin It would appear, on the other hand, as if during the course of the immunization the nerve-cells had *never come into contact* with the toxin

Certain animals are naturally immune to various microbic toxins The rat, for instance, does not suffer from a dose of diphtheria poison which is sufficient to kill several rabbits One tenth c c of diphtheria toxin was injected into the brain substance of a rat, and death followed on the third day, hence the brain of the rat is also sensitive to the poison, and as it does not die when large quantities of toxin are injected subcutaneously, it follows that the poison does not then reach the brain but is arrested in some part of the body The natural immunity of the rat does not depend upon the resistance of the nerve cells against diphtheria, but upon some other property of the body Roux and Borrel showed that similar facts obtained with regard to the rabbit as to morphin, toward which this animal is looked upon as being insusceptible In other words, the nerve-cells of the rabbit are not insensitive to morphin

All the facts go to show that in acquired as well as in *natural immunity against certain poisons*, the immunity does not depend upon insusceptibilty of the nerve cells, at least not of those of the brain The poisons are retained by other cells, which exercise a protective rôle and probably manufacture antitoxins Roux and Borrel ask *Where are those cells?* and answer that perhaps phagocytic cells are capable of also destroying the poisons produced by microbes They are not ready to insist upon this, but it would seem to them that the questions of immunity against the microbes and of immunity against the toxins will ultimately receive similar solutions

CREOSOTE NOT A SPECIFIC

The drug, creosote, has become so inseparably connected in history, in clinical experience, and in present day teachings, with the disease of pulmonary tuberculosis, that its acceptance as a specific becomes a natural consequence Such empiricism, however, is fatal to the scientific treatment of tuberculosis even though creosote does seem to be indicated in every case Creosote probably exercises its curative action in the lung because of its physiologic property of stimulating the bronchial mucosa, where it is eliminated, and its action as an expectorant, not as a specific for the disease of tuberculosis

The healthy human body is not susceptible to infection by the germs of tuberculosis because a vital resistance of the tissues prevents the development of any bacteria that may gain entrance, and those bacteria that develop in a lung to cause a miliary tuberculosis, do so because—from malnutrition, lack of exercise, the inhalation of sewer gas or dust particles, an ordinary cold or a previous attack of pneumonia—the lung tissues possess a diminished resistance and afford a suitable soil for their development A diminished resistance is probably present in the bronchial mucosa, *of which there is a vast expanse in the lung*, and when an infection is once established at a given point it is clear that the adjacent mucosa will afford slight hindrance to an extension of the tubercular process *The object of our treatment should be to* raise the vital resistance of these adjacent cells of the bronchial mucosa, in order that they may resist an extension of the disease and thus limit the tubercular inflammation to a single spot, which should mean an eradication of the disease Creosote *does* improve the resisting power of each cell, because it stimulates it to a more perfect metabolism, and if to this favorable condition there are added an abundance of good food to supply these cells with nourishment, and plenty of fresh air to supply the blood with good red oxyhemoglobin that may further assist their metabolic processes, the patient is placed under the best conditions for recovery The creosote, it will be observed, does not exercise an antibacillary action, nor does it even diminish the virulence of the tubercle bacillus, but as a treatment for tuberculosis it is the most satisfactory agent that we know, since it succeeds in establishing a condition of health in the mucosa that will help nature to overcome the disease

CORRESPONDENCE

The Jugglery of Statistics A Reply to an Absurd Editorial

Washington, D C, Oct 22, 1898

To the Editor —I desire to invite attention to the editorial comment in the *Philadelphia Medical Journal* of Oct 15, 1898, under the caption "The One Fact the Whitewashing Committee Must Explain" I would not have troubled you with this communication but that I have regarded the said *journal* as a paper of value and of increasing importance whose editorial utterances should have weight The article to which I take exception as unworthy of the columns in which it appeared, presents to its readers the large ratio of deaths from disease in the Spanish War, as the one fact to be explained, "the crux of the entire discussion," and manifestly elated with his discovery, the editorial writer exclaims in a burst of triumph "Explain us that right thoroughly and without equivocation, Honorable Sirs," etc This exuberance of diction from the editorial pen manifests that the writer sent his manuscript to the printer while dazzled by the brilliance of his discovery and without giving it that careful consideration which is needful for the reputation of the editorial columns I am constrained to look upon this as the explanation of the article Doctors are generally credited with being weak on figures, and my experience shows that they are not strong in questions of ratios, making honorable exception in this regard of the health officers who deal systematically with medical statistics I must charitably suppose that the writer in question participates in the general professional failing because I am unwilling to believe that he knowingly presented figures which did not sustain his conclusions, trusting that the latter would be accepted by readers who were unfamiliar with his arithemetical premises These premises are that There were killed in the War of the Rebellion 46,874, died of wounds 39,715, died of disease 172,907, and in the recent war killed 289, died of wounds 65 and died of disease 2565 These figures are official, and I have no exception to take to them But he continues "If we reduce these figures to percentages based on the best estimates of the numbers of soldiers participating, and place figures side by side we find

' Causes of Deaths	Civil War	Spanish War
Killed	18 1%	9 6%
Died of Wounds	15 3%	2 3%
Died of Disease	66 6%	88 1% "

Now in the calculation of these ratios no consideration is given, as claimed by the editorial, to "the best estimates of soldiers participating" nor, I may add, to the relative duration of the two wars. They express merely the relative proportion of deaths from battle casualties and disease in the constitution of the total mortality Yet from these data the editorial writer, knowingly or unknowingly, concludes that the 88 1 per cent of deaths from disease in the Spanish War, as compared with the 66 6 per cent in the Civil War is a point of the highest importance "There can be no possible question" he says "that the general mortality from disease has been greatly and indubitably lessened in the last thirty three years If so, of course the percentage mortality from disease in the Spanish War should be decidedly lower than in the war of the Rebellion Instead of this it has been decidedly higher," and the members of the Presidential Investigating Commission are called upon to take note that the medical profession regards the cause of this as the main thing that is before them for explanation

The absurdity of this may be well illustrated by adding to the statistics and ratios given above those derived from the reports of the engagement of Admiral Dewey's fleet on May 1, 1898, at Manila Dewey's fight lasted only one day The figures given for the Spanish War covered a period of five months and those for the Civil War a period of five years and two months, but as the element of time does not enter into the *calculations of the ratios criticised* this element need not be considered in the engagement at Manila Here we find that no man was killed, no man died of wounds received, but that one man, an engineer officer, succumbed to heat exhaustion or insolation Stating these figures as percentages of the total mortality we find killed 0 per cent. died of wounds 0 per cent, died of disease 100 per cent, as compared with 88 1 per cent in the Spanish War and with 66 6 per cent in the War of the Rebellion If it is needful for the Honorable Sirs to give such high consideration to the greater death rate from disease as compared with the deaths from wounds and deaths on the battle field in the Spanish War considered as a whole, how serious is the consideration they ought to give to this frightful rate of mortality from disease as compared with that from battle casualties in the Bay of Manila

It was my intention in beginning this letter to state the conclusions that are really admissible from the figures and ratios presented by the *Philadelphia Medical Journal*, but the pressure of current work at this time is very great, and I conceive that I have effected my purpose by directing attention to the unsubstantial basis on which the argument of the editorial writer was constructed

Repectfully yours, CHAS SMART,
Deputy Surgeon General, U S Army

Twins with Complications

LAUREL, IOWA, Oct 18, 1898

To the Editor —October 2 I was called to attend Mrs R in confinement and found myself confronted with a number of unpleasant conditions, not the least of which was a morbid fear on my patient's part that she would not be able to give birth to her child, or children as proved to be the case, she having been told at her previous confinement, about a year ago, when she gave birth to triplets, all still born, that she would not live through another confinement She was a German woman, large and strongly built, about 40 years of age and had given birth to five children, the oldest 14 years of age She said she had suffered a great deal at all her previous confinements and that they had been slow, lasting from twenty-four to forty eight hours She complained of being "deathly sick" and felt as if she was going to vomit

From the size and shape of the abdomen, I concluded I had a case of multple pregnancy, but the sound of but one fetal heart could be heard on auscultation Digital examination revealed an irregularly contracted vagina, due, no doubt, to the healing of her previous lacerations The os, however, was fully dilated, and I found a foot protruding, which as a strong pain now came on, I grasped, making slight traction and with some manipulation succeeded in bringing down the other foot During the next pain the body was born and the head, with chin to the front, was engaged in the superior strait Now, when good pains were most needed, the patient "gave up" and wished me to leave her to die, as she had been told that she must Finally, after a delay (which proved fatal to the child) she was delivered of a large girl weighing eight pounds Another child could be outlined high up in the fundus uteri, and digital examination showed a "cone shaped" bag of water through the os The fetal parts could not be made out The patient gave up entirely, and I let her rest an hour and a half, when, as the pains did not come on, I gave her 15 m fl ext ergot and in a short time they again became quite strong and regular Another digital examination showed that the child was not presenting, hindered, I think by the low attachment of the placenta But by making slight downward pressure from above during a pain, I finally succeeded in getting the parts to engage The sac, which was very dense, had to be ruptured, when an unusually large amount of the liquor amnii came away and I found a foot protruding almost exactly as did the first one The child, a boy, also weighed eight pounds and was alive, but minus the penis Where the penis should have been there was a slight elevation about one eighth of an inch above the surface, with an opening at the apex, through which the child urinates The placenta, which was delivered in about thirty minutes, also seemed to share in the general anomalous condition It consisted of two distinct placentæ, seemingly enveloped in a common sac They were connected at their sides by a strong fibrous band and each had a circulation of its own, there being no anastomosis of blood vessels between them I report this case because of its many bad features and of its comparatively happy ending, as at this writing the mother and baby are doing well I hope it may be of interest to at least some of the readers of the JOURNAL, who, like myself, have not practiced long enough to become familiar with this class of cases and patients

Respectfully L W PENCE, M D

ASSOCIATION NEWS

To Commemorate Joseph O'Dwyer's Name—At the meeting of the Section on Diseases of Children of the AMERICAN MEDICAL ASSOCIATION held at Denver, Colo, June 7-10, 1898, it was moved and carried unanimously that a Memorial Committee be appointed to commemorate the late Joseph O'Dwyer, with suitable powers etc, to collect such moneys and to act with other bodies for the same purpose The committee is composed of the following Dr Louis Fischer, New York, chairman, Dr J P Crozer Griffith, Philadelphia, and Dr F E Waxham, Chicago

SOCIETY NEWS

Tri State Medical Association—The Tri State Medical Association of Mississippi, Arkansas and Tennessee, meets in Memphis, Dec 20-22, 1898 Physicians attending this meeting are promised a pleasant and profitable time in the "Queen City of the Mississippi Valley" Titles of papers should be sent to Dr Richmond McKinney, secretary, Continental Building, Memphis, Tenn

Utah State Medical Society—At the recent meeting of this Society the following were chosen officers for the ensuing year President, C M Wilson of Park City, vice president, Ira A E Lyons of Salt Lake, second vice president, J W Aird of Heber City, secretary, R W Fisher of Salt Lake, treasurer E S Wright of Salt Lake, board of censors, G M Perkins of Ogden, W W Betts of Salt Lake, G L Smart of Springville, H J Powers of Ogden A J Hosmer of Salt Lake

Cumberland County (N J) Medical Society—This society held its semi annual meeting at Hotel Cumberland, October 11, with the president, Dr , A Judson of Newport, in the chair A paper on 'Peritonitis" was read by Dr Hummel of Deerfield Dr Charles P Noble of Philadelphia read a very interesting and instructive paper on "Conservatism in Gynecology" The society unanimously voted to celebrate its eightieth anniversary on Dec 8, 1898

Mississippi Valley Medical Association—The following officers were elected at the recent meeting President, Duncan Eve, Nashville, Tenn, first vice president, A J Ochsner, Chicago, second vice president, J C Morfit, St Louis, secretary, *Henry E Tuley, Louisville, Ky (111 W Ky St), treasurer,* Dudley S Reynolds, Louisville, chairman of committee of arrangements, Harold N Moyer, Chicago Chicago was selected as the next place of meeting, in October, 1899, the date to be determined by the executive officers and the chairman of the committee of arrangements

Washington, D C, Medical Society—At the meeting of the 19th inst Dr Sterling Ruffin presented the specimen and gave the history of a very interesting case of aneurysm of the aorta, which involved the entire arch, but did not give the symptoms of pulsation during life, the other usual symptoms, however, were well marked, the patient eventually dying of inanition, The subject was discussed by Dr Claytor, who referred to the latest points of diagnosis, calling especial attention to the frequent mistake of considering the presystolic murmur associated with that form of aneurysm as being of valvular heart origin, and the subsequent injudicious treatment with digitalis He referred to similar cases occurring in his own practice Dr Storch read an essay entitled "Function of the Appendix Vermiformis" The principal function which he assigned for this organ was that of a lubricant to the caput coli He considered constipation, and not obstruction by intestinal contents, the cause of appendicitis, he considered the appendix a necessary organ and its function an important one Dr D S Lamb did not agree with Dr Storch, but believed the appendix had no physiologic function He regarded the organ as a degeneration of a formerly existing diverticulum from the intestines, and being a degeneration was prone to disease He considered the only function the organ possessed was that of inducing disease and death He went into the morphology of the appendix, calling attention to its existence in certain animals and absence in others, and explained the evolution, anatomically, which appeared to explain its origin The discussion was continued in a very interesting and instructive way by Drs A F A King, Stone and J Ford Thompson

Detroit Academy of Medicine—The annual meeting of the Detroit Academy of Medicine was held October 13, and the following officers elected for the current year President, F W Robbins, vice president, Geo Duffield, secretary and treasurer, H D Jenks, trustee, J E Emerson Reports from retiring officials showed the society to be in a flourishing condition The annual address was given by the retiring president, Dr David Inglis, on "Social Factors of Today and the Future of the Medical Profession" He said that for weal or woe the steady trend of modern life is toward socialism Socialism as distinguished from individualism has already affected the medical profession in the matter of the license to practice being restricted to qualified practitioners There can be no doubt that all thoughtful medical men favor State examining and licensing boards Michigan is an unfortunate example of pure individualism in this matter Socialism, as exemplified in the change from competition to combination, is at the bottom of the steady extension of hospitals, dispensaries, railway and other contract surgeons and physicians Like the trust and department store, these phases of combination are probably permanent Socialism as exemplified in the concentration of wealth seriously affects medical incomes If, as the *Iron Age* puts it, "Prosperity has returned, but it is prosperity based on a permanently lowered rate of wages," medical incomes must also be permanently lowered Finally, as it seems likely that the way out of combination of capital for private gain will be found in the combination of capital for the public weal, the full establishment of a commonwealth, so medical men will find under the socialism so evolved an opportunity to pursue scientific medicine unhampered by the present overpowering commercialism After the regular meeting Dr and Mrs Inglis entertained the members and their wives

NEW INSTRUMENTS

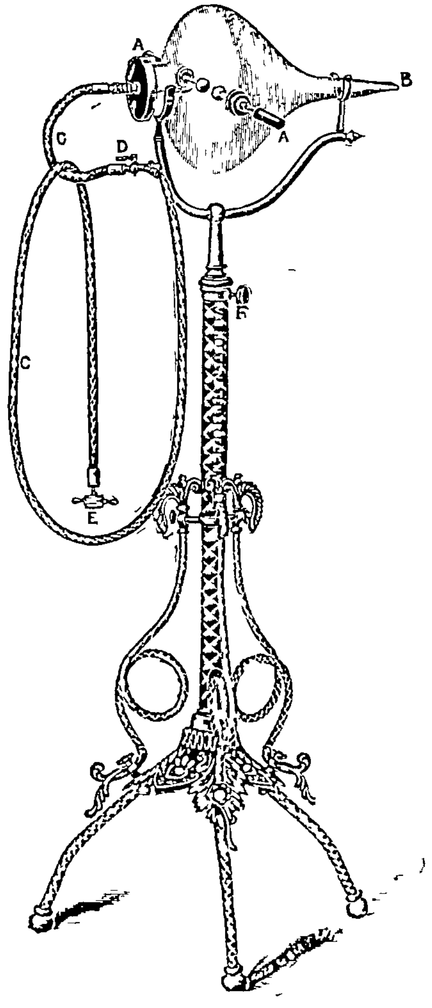
A SCIENTIFIC OZONE INHALER

BY CYRUS EDSON, M D
NEW YORK CITY

In describing this new instrument, which I have devised for the purpose set forth in the foregoing title, the adjective "scientific" has been used in order to distinguish the apparatus from the numerous so called "ozone inhalers" with which physicians and the laity are confronted in advertising columns and on every hand—nostrums which develop so little ozone that chemic means have never been able to detect it In point of fact, the word "ozone" has been so abused by misuse in connection with inhalers that it has come to mean something physicians view askance This ozone inhaler was suggested to me by a conversation with a medical friend who told me of a series of cases of phthisis pulmonalis treated by him that were greatly benefited by inhalations of ozonized air These patients had been made to inhale the air acted on by the discharge between the poles of a static machine

The familiarity of physicians with the properties of ozone makes it quite unnecessary for me to enter upon a dissertation respecting the antiseptic and disinfectant qualities of ozone It may be well, however, to point out the fact that the beneficial effect of climatic change to regions abounding in pine forests in cases of respiratory diseases due to germ infection, is generally ascribed to the presence of ozone in the air of such localities in greater amount than elsewhere

The ozone inhaler is well shown in the accompanying cut Two terminals or poles (A A) are passed into a glass receiver, about a foot wide in its greatest diameter, through holes bored in the glass for this purpose These poles are so constructed as to be separated or approximated at the will of the operator and are connected with the poles of a static machine by means of insulated wire, just as the Crooke's tube for X ray work is connected One wire carries the current from the positive and the other from the negative pole of the machine An apparatus capable of throwing at least a six inch spark is best adapted for the purpose The glass receiver has two large openings, one of which is terminated in a mouthpiece (B), while the other is connected by means of rubber tubing (C) with an air tank containing air under pressure The rubber tubing is furnished with a stopcock (D) for the purpose of regulating the supply of air The inhaler may, however, be used without this air supply When used with it, the stream of air enters the apparatus in such a way as to pass directly between the poles or terminals inside the receiver, and thence on through the mouthpiece, to be breathed by the patient When in operation, the current is seen passing through the space between the two terminals in the form of a silent discharge spray or a stream of sparks, depending on the separation or approximation of the poles The amount of ozone developed is directly under control of the operator The silent discharge when the poles are widely separated effects the development of the maximum amount of ozone, while the amount lessens as the poles are approximated The ozone admixture may be further controlled by regulating the air supply from the air tank to the receiver The amount taken by the patient may be still further graduated by having him inhale the stream of ozonized air as it issues from the mouthpiece, his face being at a greater or less distance from it, or by having him apply his lips to the mouthpiece, thereby drawing the admixture of air and ozone directly into the respiratory tract



In using ozone as a remedial means in the great quantity capable of being furnished by this apparatus, we must bear in mind that it is an exceedingly powerful and active agent, having stronger affinities than oxygen, rapidly destroying all forms of bacterial life In comparatively weak admixture with air, it is very irritating, and should be inhaled with caution The strength of the ozonized air should be carefully regulated to suit each case or violent coughing and strangling will follow its respiration With a little care, however, commencing with a very weak admixture and increasing its strength gradually until very slight irritation is apparent, then decreasing a little to the point of tolerance, it can be safely administered Its beneficial effects are almost immediate Cough and expectoration are rapidly diminished and a marked general improvement follows

I have noted also that the appetite of persons in health to whom the inhalations were given for experimental purposes, was increased, the action of the heart became stronger the face flushed, and the effects noted after administration of oxygen were apparent It is too early yet to report cases upon which this treatment has thus far been tried Suffice it to say that I have used it both alone and as an adjuvant to other treatment in a number of cases of phthisis and of bronchial catarrh, and am more than pleased with the results I hasten to give the ozone inhaler to the profession, well knowing that it will appreciate the device to be valuable, since its operation and application are founded upon sound principles

Before closing, I would add that I have modified the apparatus so as to apply a similar device to the purpose of furnishing quantities of ozonized air to hospital wards, dwellings, theaters, etc The object of this is to revivify the atmosphere of such places I believe it of importance that the air in wards of contagious disease hospitals be kept fresh by this means Benefit to the patients suffering from diphtheria and other contagious diseases must necessarily follow, if not directly from remedial effect of ozone operating as a bactericide, at least as a result of improvement of the air supply furnished for breathing

As in the case of the inhaler, the ozone admixture can be regulated and supplied in any effective strength, while the cost of application in this electric age will be inconsiderable after the apparatus has been once introduced

Messrs Van Houten & Ten Broeck of 300 Fourth Avenue, New York City, have constructed the inhaling apparatus after my designs, and caused the cut shown here to be made

20 West Forty eighth Street

RAMAUGE S NEW INTESTINAL COUPLER

A Ramauge of Buenos Ayres again presents a device for an improved button (*Semana* [illegible] *a*, S[illegible] r 1) A cylindric tube 2 c m long by [illegible] each end with a circular rim project[illegible] total diameter of the button 3 [illegible] the centre of the tube sh[illegible] the outer edges of the rims are much nearer together than the part close to the tube, thus forming a couple of partly enclosed canals encircling the tube, while the surface of the tube is left exposed between them This exposed space is studded with small holes These partly enclosed canals are packed with compressed sponge forming a couple of sponge rings around the tube held in place by the overarching rim at each end Some water is then introduced into the two ends of the intestines and a draw thread run around each edge The button is then inserted and the threads drawn tight, thus fastening the intestine around the free space in the center of the tube The water is then made to flow down to the spot and as it finds its way through the small holes the sponge begins to swell and gradually compresses the two ends of the intestine together, above the threads, until they become consolidated in the peripheral line of the serous surfaces in contact, while the central part will slough away and release the button No actual tests of the button had been made at the time of his communication

NECROLOGY

Deaths Abroad —Max Wiener, professor of obstetrics at Breslau ——Karl von Mettenheimer of Schwerin

Donald A Taylor, M D , acting assistant surgeon at Fort McPherson, died of peritonitis, October 15, aged 25 years The Doctor was a graduate of the University of Virginia At a meeting of the medical staff of the United States General Hospital at Fort McPherson, Ga , held on Oct 16, 1898, the following resolutions were adopted

Whereas, It has been our sorrow to lose from our midst our friend and colleague, Dr Donald A Taylor, Acting Assistant Surgeon, U S A , and,

Whereas, His premature death has been in consequence of disease contracted in the faithful performance of his duties,

Resolved, That we, the members of the medical staff of the United States General Hospital, Fort McPherson, Ga , do hereby express our esteem of our late friend and colleague, and our regret for his sudden loss

Resolved, That a copy of these resolutions be sent to the family of our deceased colleague, in expression of our heartfelt sympathy with them in their bereavement, and further be it

Resolved, That copies of these resolutions be furnished to the following journals for publication The *Army and Navy Register*, The *Army and Navy Journal*, The Journal of the American Medical Association, The *Atlanta Constitution*

[Signed] For the staff Wallace Neff,
Major and Brigade Surgeon, U S V
Charles E B Flagg,
Captain and Assistant Surgeon, U S A
J C Garlington,
Acting Assistant Surgeon, U S A

PUBLIC HEALTH

Toxicity of Woman s Milk with Diphtheria —The *Arch Clin de Bordeaux* for August reports a case of severe diphtheria not treated with serum, in which tests of the milk even late into convalescence proved that it was toxic for guinea pigs, hence would have proved toxic for her infant had she been allowed to nurse it

Governmental Research on Malaria —The London *Lancet* announces that a commission for investigating the various questions associated with malaria, which has been appointed by the Colonial Office and the Royal Society, consists of the following members Dr C W Daniels of British Guiana, Dr S R Christophers of University College, Liverpool, and Dr J W W Stephens, John Lucas Walker student in Pathology in the University of Cambridge Drs Christophers and Stephens will proceed almost immediately to Pavia to work in the laboratory of Professor Golgi and thence to Rome to work in Professor Cetti's laboratory The Commission will eventually proceed to Africa, when its first work will in all probability be to determine the clinical varieties of malarial fevers occurring there

Sodium Sulphocarbolate in Scarlet Fever —J J Gonzales describes (*Cronica Médica Mexicana*, October 1), his success in preventing contagion of the other children in a family when one child was infected with scarlet fever during a recent severe epidemic The isolation was very incomplete, if attempted at all His dose was 30 cgm a day for children under 3 years of age, 50 cgm for children from 3 to 10 and from this to 1 gm for older persons, administering it for more than a month and thus entirely preventing contagion in seventeen families and a hospital, protecting 139 other children exposed Two cases of contagion occurred, one showing evidences of the disease a few hours after commencing the sulphocarbolate, and the other having refused to take it at all It was tolerated perfectly in every case with no after effects of any kind

Yellow Fever —The dispatches since our last report (vide Journal, p 998), are as follows October 18, New Orleans, 2 new cases and 1 death, Wilson, 4 new cases, Franklin, 1, Jackson, Miss , 4 and 1 death, Yazoo City, 4, Waveland, 1, Madison, 2, Hattiesburg, 2 and 1 death, Poplarville, 6 new cases, Starkville, 1, Edwards, 5, Natchez, 3, Orwood, 4, Harriston, 2 Frost throughout the fever belt gave promise of a decrease in the fever, but October 19 Jackson reported 6 new cases, Natchez, 4, Madison, 5, Canton, two suspicious cases, Hattiesburg, 2 new cases and 1 death, Oxford, 4 new cases Quarantine restrictions in Northern Alabama were removed on this date On October 20, but 1 new case was reported at Jackson, Miss , 3 and 1 death at Yazoo City, 2 and 1 death at Hattiesburg, 1 at Harriston, 1 death at Warren, Ohio, 3 new cases and 3 deaths at New Orleans October 22 dispatches reported frosts through the infected districts generally, while quarantine in Mississippi was removed All traffic restrictions being removed in Louisiana trains began running regularly October 24

Sero diagnosis of Leprosy —Professor Spronck of Utrecht announces that Hansen's bacillus can be cultivated on glycerinated and neutralized potato (10 days, 38 degrees C) and continues to flourish transferred to Loeffler's gelatinized horse serum or, even better, simple fish bouillon (cod or turbot) Artificial culture produces a modified form of the lepra bacillus, resembling more the diphtheria and pseudo diphtheria acilli than the Koch bacillus It is not pathogenic for animals It is very seldom that the serum of a non leprous person will cause agglutination even at 1 in 30 to 1 in 40, but in every one of the twelve cases of leprosy he examined, agglutination was produced with 1 in 60 to 1 in 1000, except in three cases of anesthetic leprosy dating from fifteen to thirty two years, which required 1 in 20 to 1 in 40 The leprous serum will retain its agglutinating power six weeks if 1 per cent phenicated bouillon is added and air and light kept out Dried, it retains the agglutinating power a month at least Living recent cultures must be used for the sero diagnosis — *Semaine Méd* , September 28

Malt Soup for Infants —The Breslau University children's clinic has long been investigating to discover a food adapted to cases with gastro intestinal disease, and reports in the *Deutsche Med Woch* of September 28 the extremely satisfactory results attained with a food made of 50 grams wheat flour stirred in one third of a liter of cow's milk, and worked through a sieve In another bowl 100 grams malt extract are dissolved in two thirds of a liter water at 50 degrees C , and to this is added 10 c c of an 11 per cent solution of potassium carbonate The malt extract mixture is then stirred into the flour milk and the whole cooked together A table of the gain in weight in 28 cases is appended (all less than six months old), which averages very high under the circumstances, 43 grams a day in one case, fed on the malt soup 31 days None of the children had severe rachitis afterward The article concludes with an appeal for more children's hospitals, as the benefits to infants of scientific treatment and diet far outbalance the burden of the extra responsibility they would entail

The Plague in Vienna —The press dispatches of the 23d announce that the plague situation in Vienna continues extremely critical, the death of Dr Mueller, on this date, adding to the already great alarm that the city will not escape the plague Dr Mueller attended Herr Barisch, the surgical assistant at Professor Nothnagle's bacteriologic establishment, who died on Tuesday Great precautions have been taken to prevent infection from the dead and sick Dr Mueller recently returned from Bombay, where he studied the plague and brought with him some of the bacilli He cultivated the bacilli and Professor Nothnagle and he have been experimenting with them on lower animals with a view to obtaining a serum with which to inoculate against the plague The man Barisch was a servant in the laboratory, which he kept clean He also fed the dogs, cats, rabbits, and guinea pigs on which Professor Nothnagle experimented with the plague bacilli When Barisch was taken ill he was removed to the Vienna General Hospital, where the physicians, learning his last and dangerous occupation, isolated him Dr Mueller then attended Barisch When Barisch died a bacteriologic examination proved him a victim to the dread disease

Prevention of Epilepsy —Children react with convulsions to so many slight causes gastro intestinal disorders, fright, etc , that they are always standing on an inclined plane as far as these reflex phenomena are concerned, and each attack progressively increases the danger of epilepsy by lowering the "threshold of the neuron" Max Breitung of Cologne asserts that epilepsy should never be allowed to develop, and that the physician of the future will devote much energy to switching off to another track any child that shows the slightest hereditary or acquired tendency to convulsive attacks This can be accomplished by wise supervision, dietetic and physical measures and moral training at home and in school, avoiding any disturbance of the nervous system, keeping up the reserve of nerve strength and toning up the neurons so that they will subside rapidly into repose after an excitation As "dietetics of stimulations," he mentions mild electric baths, massage, tepid douches, etc , and muscular exertion, gardening, carpentering, drawing, book binding, etc He refers to the bicycle as a wholesome exercise when rationally used "but who uses it rationally? certainly not the bicyclanthropos curvatus of the present day "' He adds that this "Bahnungshygiene," as he calls it, is a seed for the future "It requires time, but the Eden of Humanity, in which, as gardeners we work, extends timeless before us Every progress in our science and our art hastens the day when the physician will be the freely chosen guide of mankind "

Not Part of State Quarantine System —Many complaints are being made concerning the quarantine detention camp at Egmont Key, and almost invariably it is thought that this camp is a part of the Florida quarantine system This is a mistake, as that camp is a creation of the United States Marine Hospital Service, is run entirely by the United States Government and is managed and controlled by the Federal authorities Neither Dr Porter nor the State Board of Health has anything whatsoever to do with the management of that station A gross injustice is, therefore done the State quarantine system and the health officer when the two are confounded Governor Bloxham has recently been petitioned in respect to the brutal, immoral and indecent environment of that camp, showing that those presenting charges believe it to be a part of the State's health protective system It is therefore necessary that the attention of the public should be invited to the great distinction between that quarantine camp and the various quarantine stations of our State Board of Health The Tampa Bay quarantine station, on Mullet Key, is, and has been for eight years, built, operated and controlled by the State Board The quarantine detention camps at Egmont Key (Tampa Bay) and those near Key West are part of the United States quarantine system, and are entirely separate and distinct from and in no way connected with the State stations —Jacksonville *Times Union and Citizen*, October 1

Sanitary Surgery —The following appeared as an editorial in the *New York Evening Post* of March 4, 1898

SANITARY SURGERY

> Attention has recently been called in these columns to the importance of the establishment in the United States of a National health organization, which should be so broad in scope and so wise in detail as to render speedily and practically available to the citizens of the whole country those new measures for the prevention of diseases which science has within the past few years made known We have deprecated the notion still prevalent in many minds as a heritage of an earlier day, that quarantine is the be all and the end all of national health organizations
>
> That this suggestion was not premature is attested by the fact now become widely known that the committee of the Senate at Washington, having the matter in charge, has reported favorably, not a bill to create a National health bureau with all its wide and beneficent possibilities but a bill to increase the quarantine powers of the Marine Hospital Service This bill, known as the Caffery bill or Wyman's bill, gives almost dictatorial powers to the Supervising Surgeon General of the Marine Hospital Service in all parts of the country, and, in its recent modifications, sanctions the establishment of a system of annoying espionage upon the State quarantines, largely ignoring the important ends for which a National health bureau is urgently demanded by the medical profession
>
> This Wyman Caffery bill seems to have been framed largely from the point of view which dominated the New York quarantine under the redoubtable Jenkins, a few years since, and which was a source of much keen mortification to the medical profession of the country Apart from the implication which this bill carries, that quarantine is one of the most important functions of a National health organization, its provisions if legalized, would place grave commercial as well as sanitary interests in the hands of a single individual, who, not inconceivably, might be more a politician than a sanitarian, more concerned in strengthening his service and his following than in fostering conditions of public and private sanitation, which, the world over among civilized people, are tending to reduce quarantine to an entirely subsidiary function
>
> We do not, of course, in suggesting such a sinister possibility, allude to the present organization of the Marine Hospital Service The medical profession is the best judge of the eminence, as a sanitarian of the present supervising Surgeon General They can best judge whether or not his administration has been signalized by absolute devotion to science to the exclusion of all political involvement of the great bureau which he directs But legislation like this must not be made for a day but should have in mind all possible personal vicissitudes of administration
>
> The so called Spooner bill now before Congress, providing

for a national health bureau of the wide scope which we have indicated, guards against the abuse of power in quarantine as in other matters of administration, by the creation of an advisory council representing the various parts of the country, which would share with the head of the bureau or commission the responsibilities of critical situations, and secure attention to the often diverse interests of various parts of the land

It will interest the student of the civilization which this country is evolving, sometimes it seems in very jerky fashion, to see whether the United States, through their representatives at Washington, are to practically ignore the great advance which sanitary science has made within the last two decades, and the high possibilities for the prevention of disease which are close at hand, and revert to such a blind and ignorant reliance as marked the era of sanitary savagery

MISCELLANY

An Enormous Brain —While the average weight of the European brain is 1380 grams, Bismarck's weighed 1867, Cuvier's 1830, Byron's 1807, Kant's 1650, Schiller's 1630 and Dante's 1420 But is weight synonymous with power?

Hernia of the Lung —There are forty cases on record and Potain adds another, the first observed in the suprasternal region Tuffier reduced a pneumocele lower down by suturing the pleura in stages, curing the hernia completely, but this would have been impossible in this case, and fortunately the intratracheal tension held it in check —*Semaine Méd* , September 28

Oidomycosis —The *Vienna klin Woch* , of September 29, describes the case of a woman of 64 years with symptoms of acute cystitis and pneumaturia The urine was found full of thrush flakes, forming a two inch sediment in a pint glass and quantities still floating The bladder was washed out twice with a thousandth solution of arg nitr , which cured the trouble so that the patient did not return The bacteriologic investigation showed that though the oidomycosis was so pronounced, yet the pneumaturia was due to the presence of the bacillus coli

Generalised Sclerodermia —The necropsy of a very severe case of this affection showed the nervous system intact, and the arteriosclerosis noted entirely out of proportion to the severity of the cutaneous lesions The dermatosclerosis was, therefore, a specific lesion, the direct effect of the cause of the disease, which must be some toxic substance affecting the connective tissue, as the toxins of tuberculosis are supposed to produce the "cutaneous tuberculides," according to a current theory In fact preceding infective diseases have been noted in sclerodermia rheumatism, typhoid fever, erysipelas, diphtheria, etc , and in the above case, syphilis —*Semaine Méd* , September 28

Stimulation before Operation —Before a major operation, Hanks of New York (*Am Gyn and Obstet Jour* , September) uses the following method of "moderate and judicious stimulation" in all cases Commencing six hours before the operation, he administers from one to three teaspoonfuls of good whisky in one ounce of hot water every hour until the time for operation, and two hours before the operation he passes into the rectum "high above the brim, if possible, from one to two ounces of good whisky in four ounces of warm, normal saline solution, adding, when it may be wise, a little tincture of opium " He believes the patients, so prepared, recover more quickly from the ether narcosis, and generally return to complete consciousness in less than one hour

Artificial Anus in the Symphysis —Roux of Lausanne cuts out a U shaped piece of bone in the upper edge of the symphysis without disturbing the rectus muscle, and brings a loop of the intestines through the hole in such a way that the vertical proximal intestine fills the upper four fifths of the U, while the distal intestine is compressed flat in the lower fifth The loop is then sutured to the bone below and the rectus muscle above If a neoplasm has to be removed, it is inspected at this time, but not removed until later, after the artificial anus is working perfectly The bony setting for the anus possesses great advantages The feces are easily discharged, bending forward, the bandages keep their place better and the subject can conceal his condition much more satisfactorily —*Cbl f Chir* , from *Revue Méd de la Suisse Romande*, 1898, No 1

To Close Defects in the Skull —Prof A Barth recently announced that a successful bony regeneration of a defect was only to be obtained by supplying calcareous salts for a foundation, which is best accomplished by filling the space with a spongy calcined bone, easily prepared and sterilized He proved his assertions on animals and—in one case of pseudoarthrosis of the tibia—on man J Grekoff reports (*Cbl f Chir* , October 1) his success in two children, both extensive defects, one quite ancient The calcined bone (shoulder blade of a calf) has healed firmly in place (five to seven months) and percussion elicits the normal sound He recommends the method in high terms to others, advising filling the defect as smoothly as possible, freshening the edges, absolute asepsis and young subjects No test has yet been made on an adult

Laryngeal Diphtheria —In the *Am Gyn and Obstet Journal* for September, Rosa Engelmann presents an analysis of 100 cases of laryngeal diphtheria She found that sex played an unimportant rôle, although the 100 cases showed a preponderance of males Age, she considers a decided factor, and the day on which the antitoxin was given had a more appreciable effect on the cases not intubated than on those intubated In the former, even as late as the fifth and thirteenth days, "surprisingly good results were obtained "

Heliotherapy Founded by Diogenes —Sir Samuel Wilkes, in the *Practitioner*, announces himself as a follower of the cynic philosopher, Diogenes He says "The remedy for consumption is not medicine, but fresh air In various parts of the globe this may be obtained Seeing that all the places best fitted for consumptives are blessed with sunshine, it is quite possible that the latter may be one of the conditions favoring recovery, it may be directly destructive to bacilli, as the warmth and the beauties of the landscape brought out by it indirectly excite the interest of the patient and revivify his nervous system Air and sunshine are the needs of the consumptive, without them no other remedies will succeed When reading at school of Diogenes in his tub, and the visit of Alexander the Great to him, I thought he was a man of very bad manners in telling the monarch to get out of his sunshine, and it was not until late years that I took a different estimate of the philosopher After an attack of influenza I went to Worthing to convalesce, requiring air and sunshine Everything else was put aside for these, they were my only wants When, therefore, as I sat looking on the sea and basking in the sun, a friend stopped in front of me to talk, he was stripping me of my only shred of comfort, and I exclaimed, 'Get out of my sunshine' I then discovered the greatness of Diogenes, who evidently knew that the sun was the source of all power "

Serum Treatment with Serum from Convalescents —Walger reports four cases of abdominal typhus treated with typhus serum, and with such favorable results that he recommends the method to others He injected 10 c c , repeating the injection in one case of relapse Weisbecker has been very successful in cases of measles, scarlet fever, typhus and pneumonia, with serum from a convalescent, and he now reports equally favorable results in thirty cases of diphtheria One injection is sufficient—from 4 to 6 or from 8 to 10 c c , according to the age of the child The serum must be obtained exclusively from diphtheria patients whose disease healed spontaneously, that is, without any injections The epidemic of diphtheria was exceptionally severe, but with these single injections the mortality was only 12 to 13 per cent The gen eral health improves at once after the injections the croupy cough is transformed at once into an ordinary catarrhal cough, and a copious perspiration occurs in nearly every case, followed by a falling temperature.—*Munich Med. Woch.*, September 27.

Optic Neuritis and Brain Tumors.—Krauss (*Phila. Med. Jour.*, October 1), in a study on brain anatomy and brain tumors, concludes that optic neuritis is present in about 90 per cent. of all brain tumors, more often in cerebral than in cerebellar, the location of the tumor exerting little influence over the appearance of the papillitis. Over the production of the papillitis the size and nature of the tumor also has little influence, while slow growing tumors are less likely than the more rapid to be accompanied with optic neuritis. He believes it "probable that unilateral choked disc is indicative of disease in the hemisphere corresponding to the eye involved," and considers it doubtful whether increased intra-corneal pressure is solely and alone responsible for the production of an optic neuritis in cases of brain tumors.

Stone in the Bladder.—With the belief of many, that recurrence of stone is especially liable to occur after litholapaxy, Cabot (*Boston Med. and Surg. Jour.*, September 29) does not agree. In his experiences, cases of recurrence after litholapaxy have, with one or two exceptions, been due to a general diathesis or local conditions. Recurrence follows the suprapubic operation also, and he concludes from his cases that the constant reappearance of a phosphatic stone in the bladder usually indicates the resistance of some local cause which should be sought and removed." He believes the suprabubic affords the best opportunity for inspection and operative treatment of the condition found. For removal of stone he thinks litholapaxy the safest operation, and usually competent to work a complete cure.

Electricity in Gynecology.—In considering the limited but fairly well defined field in which electricity may be used, not only with safety but also with advantage, Ford (*Medical News*, October 1) includes the following conditions: amenorrhea in young women not dependent on their anemia "but rather in connection with plethora, in which there is an undersized or undeveloped uterus due to perimetric inflammations, which have resulted in slight bonds of adhesions about the broad ligaments, cutting off the blood supply;" amenorrhea following long, exhausting nervous affections, with or without anemia; simple metritis, where ovaries and tubes are not infected; dysmenorrhea dependent on neuralgic tendency or on slight bands of constriction about the Fallopian tubes without pus formation; hydrosalpinx; subinvolution dependent on infection after childbirth, when there are no pus collections about the tubes or ovaries, and small fibroids in the uterine wall.

New Electric Lighting Filament.—One of the chief difficulties in electric lighting is to find a filament which will emit the light without being itself consumed. A scientific journal reports the discovery of a new substance which appears to have the qualities desired in greater proportion than any yet used. This is called osmium, the densest and most refractory of all metals, being infusible except at the highest attainable temperature. Osmium is found native as an alloy in certain ores of platinum and iridium. It is a hard bluish gray metal with an extraordinary atomic weight and enormous specific gravity. It is said to be the heaviest substance known. The properties that suggested its use for incandescent lamps are its practical infusibility, and its known resistance to temperatures in which platinum and iridium volatilize and disappear. It is well known that the intensity of light emitted by an incandescent substance increases rapidly with its absolute temperature. By heating osmium in a vacuum with an electric current strong enough to volatilize platinum it is said to attain a luminosity hitherto unknown, emitting a white light of an agreeable color, but of great intensity.—*Scientific American.*

Spirilla in Pleuritic Exudation.—In a case of pleurisy treated in the military hospital of Munich, Dr. Welke detected very peculiar micro-organisms, which he has described in the *Munich Med. Woch.* A soldier presented symptoms of pleurisy and pneumonia; he suffered from rigors, high fever, pains in the chest, etc.; on percussion there was dulness in the left side, auscultation showed bronchial respiration with rhonchi, and an exploratory puncture gave evidence of highly fetid purulent exudation. Before an operation could be performed a large quantity of this fluid was suddenly discharged through the bronchi, the fever decreased, and the patient recovered, although very slowly. During convalescence, pleurisy of the other side appeared, but passed off in a few days. In the fluid obtained by the puncture, Dr. Welke discovered, in addition to leucocytes and streptococci, a great number of filiform micro-organisms which were extremely motile, displacing the leucocytes in the course of their movements. Some of them had a fusiform process at each end, and their length was from 100 to 140μ (1/250 to 1/180 in.). By and by, their motility became less and stopped altogether in from twenty-five to thirty minutes, when the pus had become cold. The fluid discharged through the bronchi could not be examined until after the lapse of two hours, by which time the organisms were, of course, dead. It was not found possible to classify the organisms; their great strength proved that they did not belong to the bacilli, and Professor Hertwig, to whom they were shown, believed them to be either spirilla or protozoa. How they had come into the pleuritic exudation could not be ascertained; probably they had made their way into the pulmonary abscess during the act of inspiration, and finding this medium favorable to their development they had increased very rapidly.—London *Lancet*, September 24.

Rape by Boy Between 7 and 14 Years of Age.—If it be conceded, says the court of appeals of Kentucky, in Davidson vs. Commonwealth, Sept. 11, 1898, that the testimony showed that the accused was not 14 years of age, yet clearly showed that he was much more than 7 years old, and that the jury were authorized by the evidence to believe beyond a reasonable doubt that he was physically capable of committing the crime of rape, and that he was mentally capable of understanding that it was wrong to do so, a verdict of the jury finding him guilty of the offense as in this case is sustained by sufficient evidence.

Sufficiently "Visible Mark."—An accident insurance policy contained a provision that it should not cover "any injury, fatal or otherwise, of which there is no visible mark upon the body." The shoulder of the policy holder of the plaintiff in the case of Thayer vs. the Standard Life & Accident Insurance Company, was injured by a fall, causing pain, and depriving him of the use of the arm, but the only visible mark of the injury was a discoloration of the arm and shoulder. A point was sought to be made of this. But, in overruling exceptions to a judgment for the plaintiff, the supreme court of New Hampshire holds that the "visible mark upon the body" required by the policy need not be a bruise, contusion, laceration, or broken limb, but may be any visible evidence of an internal strain which may appear within a reasonable time after the injury is received.

Special Physical Examination Indispensable.—Where a civil service regulation requires an application for appointment to a position of a certain class to be accompanied by a certificate of a practising physician of good repute that he has examined the applicant, and found him free from any physical defect, etc., and a further regulation requires that, "whenever physical qualifications are of prime importance to the proper discharge of the duties in any position, applicants must pass an additional examination as to their physical condition and capacity," the second appellate division of the supreme court of New York hold, in People vs. Gleason, July 23, 1898, **that the** examination required by this second regulation must be had under the direction of the civil service commissioners, and that no other method of examination is a compliance with the rules, and it is immaterial that any other physician's certificate may have been accepted by the board as final, such acceptance being a clear disregard of the civil service regulations

Why a French Physician was Fined —A physician in France was recently fined, although not very heavily, for refusing to testify in a matrimonial action to the circumstances of an altercation which he had witnessed between the husband and wife on the occasion of a visit which he made to the family in his professional capacity The quarrel occurred immediately upon his arrival at the house, and he went away without either prescribing or giving any medical advice whatever For this reason the divorce court held that he was absolved from all obligations of professional secrecy, and was bound to disclose what he saw, just as any non professional witness would be He contended, on the other hand, that inasmuch as he had been summoned solely as a medical adviser, his presence at the scene was wholly due to his professional character, and that if he had not been there as a doctor he would not have been there at all, in which event he would have nothing to tell The smallness of the fine imposed, which was only 10 francs, indicates that the court did not deem his refusal to testify a very heinous offense, and before he was compelled to give the desired evidence the case was settled —*New York Sun*

"Deferred Annuities" for Medical Men —Annuities, so popular among the professions in Great Britain and the Continent of Europe, do not find much favor on this side of the water In addition to this being the case as to regular annuities, whereby a certain sum is paid down in cash for an annuity to commence its year at once, "deferred annuities" are rarely if ever heard of in America, although they have been adopted to a great extent in Europe and are readily obtainable from life companies here A "deferred annuity" is one under the condition of which the yearly payment commences early in life, and the annuity does not go into effect until, say, ten, twenty or thirty years have elapsed The American companies, however, make very little mention of them in their circulars and manuals, and therefore even a well informed agent connected with one of our life companies may be excused for not being informed on the subject

The "Camp Ghost" at Camp Wikoff —The following sketch of the physical human wrecks that were so numerous at the Montauk recuperation camp appeared in a New York Journal "The most pitiable sight that is to be seen at camp, outside of the hospitals, is the 'ghost' type The 'camp ghost' is the man who is not ill enough to be admitted to the hospital, but is too weak to do duty He has nothing to do but wander, and he really lacks the strength for this, but he always essays it, with the result that he drops by the wayside and lies until a jolting army wagon or hospital conveyance picks him up Or, feeling his energy waning, he essays a short cut over the succession of ground swells that exist here There was one of the Twenty Second Regulars whose knees gave out when he was in the hollow between the hillocks one morning On his hands and knees he crawled through a marsh to the summit of the neighboring hillock and there fainted Swirling banks of fog were chasing each other over the land, limiting the range of vision to a few yards all the morning, and it was not until noon that two volunteers found him and carried him to the roadway 'Such cases,' says one of the surgeons here, 'are just about beyond treatment I have not yet been able to comprehend the condition of mind and body which produces the 'camp ghost' The cause is the hardships of the Cuban campaign, repeated attacks of fever, and lack of nourishing food at the time when it was most needed Yet these ghosts are not ill in the ordinary meaning of the term There is no specific ailment They are simply devitalized It is useless to take them into the hospitals Their best chance is in plenty of fresh air and cheering companionship, although there is little enough of the latter If we could surround those fellows with the people they love and who love them, we could guarantee 99 per cent of cures It would revive their interest in life As it is, their sad faces are a contagion They droop a little more each day, until one day they droop into the hospital The next day they are more than likely to be dead On the records we put it down as exhaustion, and I guess that is pretty near it, exhaustion of all the vitalizing instincts that bind a man to this earth' "

Temple of Esculapius —The German archeologists working in Greece have excavated the celebrated Temple of Esculapius on the Island of Paros, described by several Greek authors It measures 41 25 by 19 5 meters, and is in an excellent state of preservation, though pillaged of all its treasures

Personal —Dr F E Waxham of Denver, Colo, has returned to Chicago, with office in the Columbus Memorial building and residence at 3633 Grand Boulevard

New Publication —The *Texas Clinic*, Vol i, No 1, October, 1898, comes to our exchange table It is to be published monthly at $1 00 a year, and is edited by J B Shelmire, M D, Dallas, Texas

Societies

The following recent meetings are noted

Illinois —Æsculapian Society of the Wabash Valley, Paris, October 27, Brainard District Medical Society, Petersburg, October 27, Chicago Gynecological Society, October 21, Military Tract Medical Association, Canton, October 20, Scandinavian Medical Society, Chicago, October 21, Stephenson County Medical Society, Freeport, October 13, Will County Medical Society, Peoria, October 25

Maryland —Johns Hopkins Medical Society, Baltimore, October 17

Michigan —Saginaw County Medical Society, Saginaw, October 14

Missouri —Medical Society of City Hospital Alumni, St Louis, October 20, St Louis Medical Society of Missouri, October 22

New Hampshire —N H Surgical Club and Center District Medical Society, joint session, Concord October 11

New Jersey —Camden District Medical Society, October 11

New York —Central New York Medical Association, Auburn, October 18, Jefferson County Medical Society, Syracuse, October 11, Oneida County Medical Society, Rome, October 11, Washington County Medical Society, Whitehall, October 6

Pennsylvania —Franklin County Medical Society, Chambersburg, October 18, Lycoming County Medical Society, Williamsport, October 14

Vermont —State Medical Society, Brattleboro, October 13 and 14, Vermont Sanitary Association, Montpelier, October 25

Wisconsin —Kenosha County Medical Society, October 13, Northwestern Wisconsin Medical Association and Fox River Valley Medical Society, joint session, Oshkosh, October 25

Cincinnati

Appointment —Dr Louis Molony has been appointed acting assistant surgeon in the volunteer army to be stationed in Santiago with Brigade Surgeon Lawrence Carr of this city

Dr Wallace Neff, Brigade Surgeon U S V, has been visited with a severe attack of appendicitis, at his station near Atlanta, Ga He was attended by Dr C A L Reed of this city

Ohio Volunteers —The surgeons of the First Ohio Volunteers are busy examining the members of the regiment previous to their mustering out The soldier makes a written statement of his condition which he signs, answering as to whether he has any physical disabilities, and if so, when, where and how he received them This is followed, if the man declares that he has any such disability, by the certificate of the company's commander The man is then examined and the surgeon makes his written report as to the man's condition Major Hendley is in charge of the examining

Society for Original Research —At the regular meeting, October 13, Dr J E Greiwe presented specimens of the various forms of syphilis of the brain and spinal cord

Baltimore

Medical Schools —The winter sessions of the schools are now in full swing The University of Maryland and College of Physicians and Surgeons are recovering from the effects of the adoption of the four year course in 1895, and have increased classes, especially the former The University is much advanced by the splendid new hospital and its successful school for nurses Professor Tiffany, who, owing to some disagreement with his colleagues of the faculty, had withdrawn from didactic teaching, has resumed full charge of the chair of surgery Prof Hammeter has one of the finest clinical laboratories in the country, and gastric physiology, pathology and therapeutics are demonstrated there in all the fullness of their modern development There was no formal opening at the University Prof Bevan opened the course at the College of Physicians and Surgeons, Prof Street at the Baltimore Medical, and Prof Batchelor at the Woman's Medical I understand the class at the Baltimore Medical is smaller than usual, owing to the four year rule coming into operation there for the first time with the class of 1896 What is to be the status of our new college, "The Maryland Medical," is only a matter of conjecture It opened in September with twenty five to thirty students, It has a three year course, but the sessions are of eight months The Baltimore University has a supplementary session each year in the spring months Really the number of schools has multiplied so here that the question of a name is becoming a difficulty, almost all the available terms being already appropriated We have now here seven "regular" schools, including one for women, one homeopathic school, three dental schools and one college of pharmacy

Opening Address —The medical event of the week has been the address of Prof T Clifford Albutt, of Cambridge University, at the opening of the Johns Hopkins Prof A is returning home from the Pacific Coast, where he has been delivering a series of lectures The address was largely technical There were many non medicals in the audience, including ladies The Johns Hopkins opened with 207 students, a larger number than ever before This is the seventh session There were no graduates until the fifth session, no students being admitted to advanced standing There are now thirty five women in attendance, nine being new students The first year class numbers sixty six The new buildings of the medical school are appreaching completion and will be occupied during the present session The hospital occupies four squares, but the college buildings occupy another entire square Prof Osler has been quite ill since his return from Scotland, where he went to receive the degree of LL D He has been suffering from influenza which led to pneumonia He has, however, recovered sufficiently to leave the city and is now recuperating in the mountains of Pennsylvania He expects to return and assume the duties of his chair and deanship on November 1

Centennial —We are looking forward to a great occasion next year when we will celebrate the centennial of our Medical and Chirurgical Faculty One hundred years ago the society was chartered by the Legislature of the State and given control of professional interests in Maryland One hundred and one physicians, representing all the counties of the State, were named as incorporators in the charter Organization was effected at Annapolis, June 2, 1799, the first president being Dr Upton Scott of Annapolis an Irish physician who came over with Governor Sharpe in 1753 Prof Samuel C Chew holds the office this year, having been selected as above all others in the State fitted to fill the chair during the centennial year by reason of his high standing, his ripe scholarship and his dignity The semi annual meeting of the faculty will be held next month in Frederick City, Md Through the generosity of the Messrs Frick the medical library has made great strides the past two years and now has a really fine collection of books available It is especially rich in those departments in which Prof Charles Frick was interested—fevers, renal, nervous and intestinal diseases

Washington

St Elizabeth's Hospital —The report of Dr W W Godding, the surgeon in chief of the Government Hospital for the Insane, for the year ended June 30, 1898, shows there were 1767 patients at the close of the last fiscal year, 437 were admitted during the present year, making a total of 2204 patients treated, of this number 351 were discharged, 93 recovered, 49 improved, 3 were not insane, and 197 died The general summary shows that 32 28 recovered, 16 26 improved, 2 39 were unimproved, and 31 87 died Since the opening in 1855, 10,772 cases have been treated, of which number 3478 recovered, 1749 improved, 3433 died, and 2726 were unimproved The daily average of inmates during the present year was 1798, an increase of 88 over the preceding year He asks for additional space and an increase of appropriation to care for the large number of patients, which have come to the hospital as a result of the Spanish American war, and recommends a change in the existing laws governing the commitment of the insane patients As a result of an increase of 20 per cent of patients during the past year, he asks for deficiency appropriation of $12,000 in order to settle last year's accounts

Microscopic Society —At a recent meeting the following officers were elected President, Dr H H Robbins, vice president, Prof Hall Bartsch, corresponding secretary, H H Doubleday, recording secretary, L M Morers, treasurer, Dr Robert Reyburn, curator, W H Seaman A committee was appointed to draft suitable resolutions on the death of Dr Edwin A Gibbs, a member of the Society

Clinic Pathological Society —At the meeting of the society, on the 18th inst, the following officers were elected President, Dr John Van Renssalaer, vice presidents, Drs John R Wellington and Sterling Ruffin, recording secretary R T Holden, corresponding secretary, J T Kelly, treasurer Frank Leach

Health of the District —The report of Health Officer Woodward for the week ended October 15, shows the total number of deaths to have been 100, of which number 60 were white and 40 colored At the close of the week there were 131 cases of diphtheria and 90 of scarlet fever under treatment The annual death rate for the whites was 16 29, and for the colored 23 43 There were 5 fatal cases of typhoid fever, 6 of diphtheria and 1 of scarlet fever There were 125 births, of which 99 were white and 26 colored Dr A Barnes Hope has been appointed a physician to the poor, to act during the illness of Dr William G Morgan

Episcopal Hospital —At the recent quarterly meeting of the Eye, Ear and Throat Hospital, it was announced that Bishop Satterlee had set aside the last Sunday in October as hospital Sunday, and that all collections on that day, in the local churches would be donated to the hospital fund, the Directors are endeavoring to secure an endowment of $50,000 The total number of patients treated during the past nine months, ended September 30, was 1027, 553 white and 474 colored One hundred and thirty six patients have been received into the Hospital, 173 operations have been performed, $998 has been received for pay patients

Unlicensed Dentists Fined —A Dr Crosby, who was tried and convicted on the charge of violating the law regulating the practice of dentistry, by engaging in practice without a license, was fined $50 by the judge of the police court The local dentists are highly gratified by the enforcement of the law So far, they have been much more successful in enforcing their Act than the doctors have in enforcing their regulation

Philadelphia

Contributions from the Public Schools —Although members of the medical profession are constantly doing little acts of charity for which there is seemingly no recompense, the good seed sown must surely bring forth its just reward An example of what this means in dollars and cents, is seen in the penny contributions of school children for the benefit of sick soldiers in the different hospitals of this city and to be distributed as follows Medico Chirurgical $584 80, St Agnes $408, University $248 90, Presbyterian $152 35, St Joseph's $145 55, German $163 20, Episcopal $115 60, St. Mary's $58 50, Jefferson $138 75, Hahnemann $81 60, Polyclinic $40 80, St

Timothy $8 18, Samaritan $8 18, Women's Homeopathic $54 40, Methodist $36 75, other hospitals $76 20 Total $2,338 11

Sick Soldiers —There have been treated in all the hospitals of this city a total of about 2500 sick soldiers Since September 12, Maj D C Peyton, a brigade surgeon, has had full charge of the work here and has a corps of eight assistant surgeons to transact the business necessarily entailed upon that department The following is the method of caring for the convalescents, according to the *Ledger* "Men discharged from the hospital report first to the office with their hospital certificate, stating that they are convalescent They are then given sick furlough and sent to the quartermaster, who furnishes transportation and commutation of rations at the rate of $1 50 a day for the time necessarily taken in traveling to their homes If a soldier is weak and has some distance to go, the quartermaster, on certificate from the surgeon's office, furnishes sleeping car accommodations If in need of clothing, he is furnished what is needed from the quartermaster's department on request of a surgeon When hospitals notify the surgeon's office that certain soldiers are ready to be discharged, clothing is procured for them through the quartermaster's office and this is in many cases sent direct to the hospital, so that it is ready when discharge from the hospital is given

Memorial to Dr Joseph Leidy —At a recent meeting of the Academy of Natural Sciences of Philadelphia, Dr Edward J Nolan presented a memorial of the late Dr Joseph Leidy The gift consisted of five volumes containing drawings and writings by that author Dr Leidy at one time practised medicine in this city and for several years was professor of anatomy of the University of Pennsylvania, where he was much esteemed by the faculty and students He is probably best known for his studies in the lower forms of animal life, comparative anatomy, and for his able and painstaking work of estimating the ages of stalactites and stalagmites of the Luray Cave, Virginia Dr Leidy was a thorough scientist, investigator and teacher, and his fame extends throughout the world

Lecture by Dr Albutt —Dr Thomas Clifford Albutt, who has been traveling quite extensively in America and who occupies the chair of the theory and practice of medicine at Cambridge University, recently lectured to the graduating class of the University of Pennsylvania The speaker was introduced by Dr James Tyson, who lectured upon "Diseases of the Arteries in Association with Apoplexy " Dr Albutt recently arrived from Baltimore, where he was the guest of Professor Osler of the Johns Hopkins University

Homeopaths Want Insane Hospital —At a meeting of the Homeopathic Medical Society of this city, at which time it is stated 100 delegates were in attendance, mention was made of the overcrowded condition of the insane asylums of the State of Pennsylvania As matters now stand, these unfortunates are being cared for by the regular profession to the disadvantage of those who practice according to the tenets first promulgated (but not now practiced) by Hahnemann In order to correct this discrimination a committee was appointed and instructed to use urgent means to have the subject brought before the proper legislative bodies We await results

Testimonial Performance – Arrangements are being made by members of the Ladies' Aid Society of the Medico Chirurgical Hospital for a testimonial performance for the benefit of the sick soldiers in that institution The Medico Chirurgical has shown great enthusiasm in bringing the sick soldiers to the city through the medium of hospital trains, and deserves great credit for the manner in which it has increased its facilities on so short notice This action, therefore demonstrates the enterprise and capabilities of the men who comprise its managers and teaching faculty

Want of Co operation —Some time ago citizens of Germantown held a meeting, at which time a committee was appointed to devise ways and means for the erection of a children's hospital It is stated, however, in the lay press that letters have been received from residents and business men who were appointed, declining to act as members of the board of directors It is stated that contribution boxes have been placed in different stores and offices for the benefit of the hospital fund, and committees have been appointed to draft rules and by laws and to procure a charter Invitations have been addressed to fraternal orders in Germantown asking financial aid for the institution

Evading Vaccination Law —The fact has reached the board of health of this city that the compulsory vaccination law regarding school children is being evaded by the wholesale A resolution has been passed by the board of education asking that the board of health be notified of the "large percentage of non vaccinated children attending the schools, the children having been admitted upon certificates signed without proper evidence " It is further stated that the board of education has passed a resolution that the board of health be requested to disinfect the schools of this district or to provide the means for doing so The disinfectant which was recommended was chlorid of lime and it was thought best to instruct the janitor in the proper use of this

Addition to Samaritan Hospital —Owing to the increased amount of work by this institution, the managers have decided to buy the dwelling house adjacent to the property and convert it into a department of the hospital The entire property has a frontage of fifty feet and extends eastward a distance of 230 feet

New Medical Laboratory —Among the many other improvements going on at the University of Pennsylvania, another laboratory is to be built To stimulate a spirit of friendly rivalry, Provost Harrison submitted the matter to the junior members of the architectural department for a proper design, but the jury of award has so far been unable to decide on whom the honor will be conferred

Verdict Against Telephone Company —Dr John Marshall, dean of the Medical Department of the University of Pennsylvania, was recently awarded $737 against the American Telephone Company for injuries sustained to shade trees at his summer home In the construction of a line for the company along the estate some sixty or seventy ailanthus and locust shade trees were destroyed, thus injuring the property

Report of the National Relief Commission —The National Relief Commission which has so liberally provided for the sick soldiers in the field and in the hospitals of the different cities, has reported contributions of money and supplies aggregating thousands of dollars The last report, made public by Mr George C Thomas, treasurer at the banking house of Drexel & Co , is Cash, etc , $76 631 57 , value of supplies to date, $40,325

Mortality Statistics —For the week ending October 22, there were reported to the Bureau of Health a total of 389 deaths, of which 122 occurred in children under the age of 5 years The total number of deaths is an increase of 58 over that of last week and an increase of 13 over the corresponding period of last year

Soldier Patients —The government recently transferred twenty five sick soldiers from Camp Meade to this city, where they are being treated at the Woman's Hospital

Society for First Aid to Injured —A society has recently been formed here for the purpose of giving instruction in "home nursing' and to render "first aid to the injured " Lectures will be given at stated times in suitable rooms, both in this city and throughout the State of Pennsylvania

Reception —Members of the Philadelphia Medical Club recently tendered a reception to Dr W L Rodman, professor of surgery in the Medico Chirurgical College A representative body of physicians attended

Red Cross Hospital —Members of the Red Cross Society of this city have secured a site for a hospital at the corner of Twentieth and Cherry Streets, and are rapidly putting in equipments necessary for the care of patients soon to be admitted A committee has been appointed, consisting of several physicians and lay members, who will act as the board of managers

Louisville

Garvin —Dr Samuel H Garvin has just been re elected jail physician for the ensuing four years The place is awarded by vote of the justices of the peace of Jefferson County Dr Garvin is a native of Louisville, and has spent the best part of his life in this city He has served as jail physician nearly twenty two years, under both republican and democratic administrations There was but one opposing candidate

Morgan —Dr L C Morgan of Dugansville was the victim of a dastardly attempt at robbery on the 4th inst While on his way home from a neighboring town, about 10 P M , he was decoyed into a house by three negro men, who told him a colored woman was very ill and in need of a physician's services When the Doctor entered the house the negroes set upon him for the purpose of robbery The Doctor drew a pistol, but one of his assailants shot him with both barrels of a shotgun before he could make any resistance He remained conscious long enough to give a description of his assailants, and they are now under arrest and close guard, as there is great talk of lynching

Koehler —Dr Henry H Koehler has announced that his practice will be limited to genito urinary and skin diseases from this time, with an office at 1001 Fourth Avenue

Johnston —Dr Geo Ben Johnston of Richmond, Va , en route to the Mississippi Valley Medical Association, where he delivered the address in surgery, was the guest of Dr L S McMurtry at a dinner on the evening of the 10th

Medico Chirurgical Society —This society's membership has been depleted by the death of Dr John A Larrabee, and the resignation on account of removal from the city of Drs Wm L Rodman and Jno L Howard Dr P L Butler and Dr T C Evans have been elected for two of the vacancies, and Dr H H Grant is in nomination for the third

Marvin —Dr J B Marvin and family have returned from a three months' sojourn in Europe

Pharmacy —The regular meeting of the State Board of Pharmacy was held in Frankfort, last week, for the purpose of examining applicants for license

Quarantine —Upon the advice of the State Board of Health the Commercial Club, one of the principal organizations of business men in the city, has issued a proclamation, inviting yellow fever refugees from the South to Louisville, as was done last year As a result there has been a great number of the Southern residents in the city during the past three weeks

Cattle —Drs F T Eisenman and J G Gashin respectively State veterinarian and State bacteriologist, have returned from the meeting of the Interstate Association of Live Stock Sanitary Boards, and are preparing their report for submission to the governor, in regard to "ticky" cattle One of the chief points developed at this meeting was the fact that cattle dipped in dynamo oil and sulphur can be safely mixed with northern cattle, and when inspected by either State or Federal authorities, can be shipped north at any time of the year It was decided that the open season should extend from November 1 to January 1, when cattle can be shipped north for immediate slaughter It was determined to ask the Secretary of Agriculture to so change the quarantine laws of Oklahoma, Kansas, Missouri, Tennessee and Texas that cattle from all points below the quarantine line may not be shipped to points above the quarantine line, unless intended for immediate slaughter The only way cattle may be admitted above the quarantine line is by inspection by Federal and State authorities after being dipped A resolution in line with the above was sent the Secretary of Agriculture by the Louisville Live Stock Association endorsed by the State Board of Health

State Board of Health —The State Board of Health held its annual session at the Galt House on the 20th inst , with the following members present J M Mathews, president, J N McCormack, secretary, of Bowling Green , J H Letcher of Henderson , J H Samuel of Maysville and Wm Bailey of Louisville The report of Secretary McCormack was a review of the Board and detailed much important work done, characterized by the Secretary as the most active and anxious in the history of the Board This anxiety was caused by the yellow fever epidemic in the South and the number of refugees passing through the State , the prevalence of smallpox which was so widely epidemic in the State and in separated districts The inspection service of the Board and disinfection on board trains was reviewed by the report, and the obstacles thrown in the way of the Board by one railroad was mentioned Attention was called to the fact that the epidemic of smallpox necessarily made a heavy drain on the appropriation of the Board, and that it is practically without funds at present. It was stated that the General Assembly is adding new work to the Board every year, but is making no increase in the appropriation The increasing prevalence of scarlet fever, diphtheria and typhoid fever was mentioned and the alarming death rate from these causes, causing more deaths than yellow fever and cholera have in the history of the State Dr McCormack commended the work of the State veterinarian in cases of Texas fever, anthrax and glanders which have appeared among the cattle and horses in the State It was stated that owing to the increase of the routine work of the executive officer of the Board it would become necessary shortly for him to devote his whole time to it The amount expended by the Board was $3,544 20 Action was taken at this session on the cases of several who have been guilty of unprofessional conduct or quackery in the State Dr Adaline Bell of Paris, who appeared before the Board to stand the required examination for candidates to practice osteopathy, had failed to come up to the standard in the subjects upon which she was examined, and she was refused a license Dr G N Murphy of Bowling Green, who claims to cure what physicians generally recognize as incurable, and guilty of other unprofessional conduct, was represented by an attorney and his case set for hearing on November 7 Mr Aaron Kohn, attorney for the Board, presented the report as an answer to Harry Nelson, who has been practicing osteopathy The answer says for the Board that osteopathy is simply a perfected system of quackery and empiricism, and denies that it requires any learning or ability to "become versed in the pretended doctrines" of the system The reply says that Nelson has never applied to the Board for a license to practice and has refused to submit himself or his qualifications to the provisions of the statute enacted by the legislature The reply concludes that to allow Nelson to practice would be to sacrifice the lives, health and limbs of the citizens of Kentucky Notice was prepared to be served on P H Woodhull of Bowling Green, also an osteopath, to appear before the Board on November 8, and answer charge of unprofessional conduct The Board adjourned to meet again on November 7

Chloroform —A death from chloroform occurred at St Joseph's Infirmary on the 20th inst The patient was a police man who was to have a toe amputated, and was found in good condition to take an anesthetic, which was administered by the interne of the hospital There was a prolonged stage of excitement and much struggling and the patient died in this state before the operation had been begun

Druggists —Several of Louisville's retail druggists have just returned from St Louis, where they attended a meeting at which the National Retail Druggists' Association was organized The Louisville druggists represented the Louisville Botanical Association and the Kentucky Pharmaceutical Association One of the representatives, in an interview, stated that much was done at the meeting which would aid the druggists of this city in getting away from the cut-rate business, which has demoralized the retail drug trade in the past two years Resolutions were adopted calling upon manufacturers to cease selling to department stores, to rabid cut rate druggists and to retailers in large quantities They also requested the assistance of all retailers and jobbers and manufacturers in having the medicine tax remitted, or if that be not possible, to have the Government remit the tax on such simple remedies as druggists may put up themselves according to public formulæ This meeting was held at the time the Wholesale Druggists' Association and National Proprietary Medicine Manufacturers were in session, yet the roll call showed twenty one States represented and about 150 in attendance

THE PUBLIC SERVICE

Movements of Army Medical Officers —The following *named* officers have been ordered to duty in connection with the mustering out of volunteer commands Major Ezra Woodruff surgeon U S A Ft Trumbull Conn for Rhode Island Vols Major Augustus A De Loffre, surgeon U S A Austin Texas for Texas Vols Major Charles K Winne, surgeon U S A Ft Crook Neb for Nebraska Vols Major W I *de* Niedeman brigade surgeon U S V , to Jefferson Bks Mo *for the* 1st Missouri Inf Major Timothy E Willcox surgeon U S A to New York City for New York Vols Major Louis W Crampton surgeon U S A Ft McHenry Md for the 5th Maryland Inf Major Geo W Crile brigade surgeon U S V from Cleveland Ohio to Ft Sheridan Ill *for the 1st* Illinois Cav Major Elmer F Heg brigade surgeon U S V from the general hospital Ft Myer Va to Omaha Neb for the 2d Neb Inf Major John P Dodge brigade surgeon U S V from Camp Wikoff, Montauk Point L I to Columbus, Ohio for Ohio Vols Major Eugene L Swift brigade surgeon U S V from Camp Wikoff to Concord N H for New Hampshire Vols Capt Chas Willcox asst *surgeon* U S A *to* Columbia S C for South Carolina Vols Capt Chas Lynch asst surgeon U S A from Camp Frank Ardmore Ind Ter to *Little Rock*, Ark for the 1st Arkansas Inf Capt Henry D Snyder asst surgeon U S A from Ft Ethan Allen Vt to Burlington Vt for Vermont Vols First Lieut Weston P Chamberlain asst surgeon U S A from the general hospital Ft Monroe Va to Richmond Va for the 2d Virginia Inf and Acting Asst Surgeon Alexander McL McMaster his orders to Cuba being revoked to Philadelphia Pa for Pennsylvania Volunteers Capt Francis A Winter asst surgeon U S A, and Acting Asst
